The ATTORNEY-GENERAL said he was not quite clear as to what really they were entitled to against these third parties on this point; but he contended that he was entitled, as of simple right, to an order for costs in the action, and the appeal as against them, they having appeared as the real defendants, and conducted the whole matter on an indemnity. He should have been glad to have had time to consider more thoroughly the question of the injunction. Having cited various authorities in support of his contention the Attorney-General, after further argument between the Judges, himself, and Mr. Aston (who followed on the same side), asked leave, if necessary, to amend the statement of claim, so as to put the Brush Company in the position of defendants.

Sir HORACE DAVEY, for the respondents, argued that if the plaintiffs deliberately chose to sue Holland, who used the lamps, instead of suing the persons who, it was alleged, made and furnished the lamps, it would be contrary to all precedent to allow the plaintiffs, after having got judgment, to amend by making the Brush Company defendants for the purpose of obtaining relief against them.

LORD JUSTICE COTTON: I do not think we need hear you further on the question of amendment; but do you object to an order being made for costs against you?

Sir HORACE DAVEY: As a matter of fact my clients do not care, but if your lordship asks me whether, as a matter of form, it would be right, in my submission it would not. I do not, however, think the question of costs worth discussing, because we intend to pay the costs.

Digitized by Google

The ATTORNEY-GENERAL having replied,

LORD JUSTICE COTTON said the point raised was a curious one, but it arose simply after judgment. The plaintiffs now claimed to treat the third parties as if they were defendants, not only in the way of making them pay the costs, but also in the way of granting relief against them by granting an injunction and consequential relief. As regarded that he thought that the plaintiffs were wrong. Third parties were not defendants. If a plaintiff had a direct claim against a third party, as soon as that was known the proper course was to amend the statement of claim and make him a defendant, and then the Court had all that jurisdiction as against the defendant which was obtained by serving that party with a writ and bringing him in as one of the parties to the action. Why that was not done in this case he could not understand, except that possibly the plaintiffs did not like to bring in another person against whom they would be liable for costs if they failed, as they did before Mr. Justice Kay, as regards the violation of the Edison patent. One did not wish that there should be unnecessary litigation, but he did not see that, for the best reasons, they could assume a power which, in his opinion, they had not got. It would have been very easy when the third party came in and desired to defend the action to obtain directions that he might have that liberty given on his undertaking to submit to whatever judgment the Court might think fit to give against him as being really the person who ought to have been made the defendant; but that was not done. The order which was made was simply in these terms—that he should be at liberty to appear at the trial of the action and take such part therein as the judge should direct, "and the said Anglo-American Brush Electric Light Company shall be bound by the decision of the Court in this action in any question as to the above indemnity which may arise between that company and the defendant." The plaintiff was satisfied with that. He ought to have said "No, that will not do for me; other terms ought to be imposed upon the third party." The proper course for the plaintiff to have brought the third parties within the region of the jurisdiction of the Court would have been to have amended his statement of claim, and to say that the third parties were the real persons who were disputing their rights in the patent, and who were making those things which the plaintiff alleged were an infringement of the patent. That course, for some reason which he did not know, had not been taken. In his opinion the Court had no jurisdiction to make a decree against this third party, as if he was a defendant, or to grant an injunction against him, and to grant damages against him in this action. It was a new departure. Whether the Anglo-American Brush Company would be unwise enough to dispute the plaintiffs' right as regarded this patent when another action was brought against them he could not suppose. Then the Attorney-General asked leave to amend, and Mr. Aston said, that he (the learned judge) had frequently expressed the view that they ought to make such order as the Court ought to have made below, and to make such amendment as might be necessary. What was the course taken by the plaintiffs on the trial before the Court below? In the Court below they never asked for this relief as against the third party. It was very true there was an expression by Sir Horace Davey which was relied upon that the third party ought to be put in "direct relation" to the plaintiffs. He did not quite understand what that meant; it was not as clear as Sir Horace Davey's expressions usually were, but the parties did not act upon that. It might have been material then, because all the costs that were given were the costs of the defendands as regarded that part of the action in which the plaintiff failed. The costs were given against the defendants as regarded that part of the action in which the plaintiffs' succeeded. In his opinion it would be wrong under those circumstances, and having regard to the course which was adopted by the plaintiffs, now to grant liberty to amend to enable the Court to grant different relief against the third party other than that which was asked for at the trial of the action. As to the question of costs, the third parties having appeared upon the appeal, and having been served with notice of appeal, there would be no difficulty about making an order against them for the payment of the costs of the appeal, and in his opinion the Court had jurisdiction under Rule 54 to make them pay the costs. Therefore, as regarded this part of the action, he thought it would be wrong to alter the judgment, but as regarded the other part of the action they might, when they altered the judgment of Mr. Justice Kay, make an order against the third party, as well as against the defendants for the payment of the costs of the appeal.

LORD JUSTICE LINDLEY said that in substance the third parties were the people who fought the plaintiffs, and if he had tried the case, and come to the same conclusion as he had done upon the merits, and had been asked to make the third parties defendants, he should have done it without the slightest hesitation, and he was not at all sure if he had been sitting alone upon appeal that he would not have done it now. He thought there was a power to do it; but he would not differ from Lord Justice Cotton on that point. There was a little doubt as to whether it ought to be done quite so late, but he thought no conceivable injustice would be done; there were no merits in question, and it was a mere matter of form. There would, therefore, be no amendment, and as to costs he concurred in the decision of Lord Justice Cotton that those who really fought the plaintiffs should pay the costs.

The London Electric Supply Corporation (Limited) v. Roberts, jun.

In the Westminster County Court yesterday (Thursday) an action was brought by the London Electric Supply Corporation (Limited) against Mr. Roberts, jun., the professional billiard player, of 99, Regent-street West, to recover a sum of money for light supplied. The defendant put in a counter claim for damages, by reason of the failure of the light, consequent loss in his business, and also claimed £10 compensation for allowing the company to fix a pole on the roof of his premises for the purpose of carrying the wire. For the defence it was alleged that on several occasions the light failed, and gas had to be resorted to, and that in consequence of that the company had been given notice to discontinue the supply, but had failed to do so for some time afterwards. It was proved on behalf of the company that the pole on defendant's house was erected expressly for him, and was what was known as a terminal pole. The Judge found for the plaintiffs on the claim, and for the defendant on the counter claim for £5. 10s.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *February 9th*, 1889.

A very interesting idea of the amount of inventive work being done in the field of electricity is furnished by the summary which is contributed this month to the New York *Electrcal Engineer* by Mr. T. D. Lockwood of the patents on electrical and related inventions issued from the Patent Office during 1888. It appears that the number of such patents is no less than 1,503, or 7·67 per cent. of the total number of 19,585 patents of all classes. Of the electrical patents no fewer than 365 relate to arc lamps, incandescent lamps, fixtures, motors, and methods of distribution for light and power. Supplementary to this class are 347 patents relating to primary and secondary batteries, dynamos, magneto machines, dynamo regulators, governors, and instruments of measurement, &c. The old class of telegraphs includes only 64 patents, but in electric signalling there were 185, and in telephony no fewer than 202. These figures go to show that the two fields being most actively developed at the present time are those of telephony and the utilisation of heavy currents. The indications are that the present year will show no falling off from the large total above given, but that in all probability it will be exceeded. It is to be noted that no fewer than 137 patents related directly to electric rail ways and motors for that work, and the present extreme activity in this field is calculated not only to greatly increase those figures, but to create a number of subordinate classes of considerable extent. There is at present no sign of decrease in the creative and adaptive power of our leading inventors. Thus it is said, for example, that Mr. Edison alone has some 200 or 300 applications now filed in the patent office, and I have occasion to know that the attorneys of other well-known electricians are also as busy as they can be.

A great many of our American inventions and ideas have already been welcomed abroad, and the figures that I have given above go to show that a great many more will soon be offered for exploitation in Europe as well as here. It seems likely that attention will be drawn to the development of electricity in America by the exhibits that will be made at the approaching International Exposition at Paris. There is every promise that, no matter what may be the show in other departments, America will be at least well represented so far as electricity is concerned. It is currently reported that Mr. Edison will spend from £8,000 to £10,000 on his personal exhibit, all his inventions being grouped together in a space of 8,000 square feet in the machinery hall. This exhibit will not only trace Mr. Edison's evolution as an inventor, but will also illustrate the development of his inventions on a commercial basis. I hear that very elaborate preparations are now going on for this exhibit at the Edison laboratory, Orange, New Jersey, where Mr. W. J. Hammer, who is noted for his success in this direction, has been entrusted with full charge of the work. I also hear that there will be a very interesting personal exhibit made by Prof. Elihu Thomson, who has also been fertile in the development of electricity in a number of directions. The list of exhibits also includes a number of new motors, telegraph systems, &c., and it may be taken for granted that American dynamos and lamps will do no small part of the lighting which is expected to be such a feature of the exhibition every night. The exhibition proves a very attractive "card" for all our transatlantic steamship lines. It is already practically impossible to secure accommodation from this side to Europe during the early summer months. I think I mentioned already that a goodly number of our electricians and electrical engineers will be going over, and they may be expected not only to take charge of

Digitized by Google

various big installations, but to participate in the electrical conference. They will also be joined by large numbers of our civil, mechanical and mining engineers. It is said that the rush for berths on the steamer which was to be set aside for the combined excursion of the engineers has already been so great that it will be necessary to run another special steamer from Philadelphia, and even then there will not be by any means room enough.

Some little attention is being directed just now to plans for utilising the enormous waste water-power of Niagara. I do not know whether English engineers take much interest in the subject, but as they are not averse to big projects I presume they have given the matter some little consideration, and, if I am not mistaken, Sir William Thomson himself has discussed it seriously. Your readers will doubtless be interested to hear that a very ingenious project, which is described in the *Electrical World* this week, has just been suggested by Mr. S. H. Hamilton, of Washington. It can be readily believed that no project would be tolerated for a minute that involved the construction of any kind of works in front of the Falls, where they would be in full view of the spectators, and would be a blot on the magnificent scenery. Of this class was one scheme which was widely discussed in the papers not long ago, which proposed to moor a string of barges right across the lip of the fall so that their wheels at the stern would operate flexible shafting and transmit power by that means to machinery on shore. The only project that up to the present time has amounted to anything is that by which some 5,000 horse-power is now used in the American town of Niagara Falls by means of a canal which takes in the water above the upper rapids, and which discharges itself just below the passenger suspension bridge which was wrecked by storm the other day. This canal is, of course, in no way detrimental to the scenery, and it has therefore been proposed to enlarge and extend it. The Hamilton scheme is of a quite different type, and proposes going in behind the Falls, back of the water as it precipitates itself into the basin below, and there in chambers excavated from the rock, erecting vertical pipes which shall catch a large portion of the water on the inner side of each fall. As the water is estimated to be about 15ft. thick as it goes over the Falls, it will be seen that such pipes could be ranged along the inside of the Falls, and take into them a large quantity of water without giving any evidence whatever of their existence. Mr. Hamilton proposes to utilise the power obtained from turbines at the base of the pipes, in driving shafting to which are belted dynamos, and the current from these dynamos is to be utilised not only in lighting and supplying power for manufacturing purposes in the immediate neighbourhood, but is to be transmitted 25 miles to Buffalo. Mr. Hamilton is in earnest about his scheme, and has already obtained estimates from leading companies and firms as to the cost of apparatus for the initial plant of 500 or 600 horse-power. He has already formed a company with a capital of $20,000,000, to raise funds for prosecuting the work, and is now moving in the New York State Legislature for permission to sink his shafts for the construction of the subterranean chamber in which the dynamo will operate. He believes that everybody who visited Niagara would also wish to visit the dynamo room and take lunch at the restaurant there, and probably he is not mistaken.

It is somewhat singular that the *Scientific American* this week also publishes and illustrates another scheme by a Mr. M. Maginn, a mechanical engineer, of Chicago. Mr. Maginn's proposition is to excavate a cavity or drift under the Falls, where the flow of water will be continuous. In this recess, which will accommodate various machinery, is to be placed a stationary iron truss designed to carry a travelling frame sufficiently heavy to support an overshot steel water wheel of 60ft. diameter, with shafting and spur gears and intermediate shafting and gearing connected up with dynamo machines. It is designed to place upon the travelling frame four mammoth dynamos of 25,000 horse-power each, and four smaller dynamos upon a suspended frame directly underneath. The travelling frame is to be moved in and out by means of a hydraulic cylinder, operated by a steam force pump on the river bank, in this way receiving more or less of the force of the water fall. The electric current generated in this way is to be distributed in the usual manner. Experts here are decidedly in favour of the Hamilton scheme as compared with that of Maginn.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *February* 20, 1889.

If the work actually done only partly corresponds to that spoken of, it will not be long before Paris takes the lead in public and private electric lighting. Mr. Popp alone, interviewed by reporters of the *Figaro* and *Petit Journal*, has declared that he is erecting a steam station of 12,000 horse-power, which will be ready to work in a few months, independently of the other stations necessary for the distribution of the current to 150,000 incandescent lamps, which will be ready before two years. M. Popp added that he was preparing a plant for lighting with arc lights the whole line of the Boulevards, the Avenue de l'Opéra, Rue de la Paix, Rue Royale, &c., and hoped to start this lighting on the day of the opening of the Universal Exhibition of May next. I am afraid that Mr. Popp takes as already done what he wishes to be done, and that the list of the streets lighted by that time will suffer a large reduction. However, great efforts are being made in every quarter, and if all that is wished is not accomplished in the time promised, there is no doubt that before long Paris will become, in fact, the "Ville Lumière."

The Palais Royal Station increases its number of lights every week. At present there are no less than 3,000 lamps at work. The station has been fitted up for feeding 10,000, and this number will be certainly attained by the end of the current year. Meanwhile, pending the time when the mains from the central stations recently voted will be ready to distribute current, private installations are rapidly being fitted up. The Gare St. Lazare, with a plant for lighting the station with 150 Cance arc lights, and the Terminus Hotel, with 2,000 16 candle-power incandescent lamps, may be mentioned as some of the largest. I may add that there is a talk of lighting the Chamber of Deputies by electricity, and of extending the electric lighting of the Salle des Séances of the Senate at the Palais du Luxembourg to other parts of the building. The town of Cambrai is also discussing the question of the introduction of the electric light.

The late snowstorms have been very prejudicial to the working of the telegraph lines in France; three wires on the Paris-Marseilles line are in an unworkable state, the lines to Nimes and Montpellier are mixed together, the lines between Paris and Montpellier, Nimes, Avignon, Toulon, Cannes, and Agen are interrupted, and the same with the lines to the Bourbonnais. It is to be hoped that these accidents will serve as a lesson to the Postal Telegraph Department, and that all the telegraphic wires will be quickly laid underground. I have to announce a great fall in the prices of the shares of the Société des Métaux, and it is to be hoped that it will coincide with a reduction in the prices of the copper.

NOTES FROM BRUSSELS.

(FROM OUR CORRESPONDENT.)

BRUSSELS, *February* 18, 1889.

The Brussels municipality has already received several proposals with regard to the electric lighting of the centre of the town. M. Humbert, Belgian representative of the Thomson-Houston Company of America, has offered to light the Boulevard Anspach and the Boulevard du Nord for nothing, on the condition that the town authorities allow him to run overhead wires to the large buildings around the Bourse. The Thomson-Houston Company propose to establish a central lighting station in an outhouse belonging to the Van Volscerm brewery, which is close to the Grands Magasins Thierry. In addition to this station two more are contemplated; one in the Rue des Bouchers and the other in the Rue Royale. The object of the former station is to light the Galeries St. Hubert and other buildings in this district. This neighbourhood has also been well canvassed by M. Thierboom, who received considerable support. At the very moment, however, when this gentleman was about to instal his engines and boilers, the authorities raised objections owing to the proper permission not having been obtained. The Thomson-Houston people have now taken the matter up, and want to erect their plant in the buildings belonging to the old Salle des Ventes. M. Thierboom, however, is once more in the field, and this time with capital at his command, so that the Thomson-Houston Company will not have it all their own way. The third station contemplated by this company will be situated in some outbuildings belonging to the Banque Delloye et Cie., and it is intended to supply current to the big banking establishments in the Rue Royale and to the Théâtre du Parc. It is very improbable that the authorities will entertain these proposals, as they know very well what

Digitized by Google

value is to be attached to all offers of gratuitous lighting. Moreover, the city engineer, who has been several times to Germany to study the question of central station lighting on the spot, does not conceal his preference for the system adopted by a certain powerful firm in that country.

The Lalaing electric light mast, intended for the square of the Nord-Est Quartier, will shortly be erected. The Government made a present of this mast to the town of Brussels, and promised to pay half the costs. In spite of this assistance the share of the town for hydraulic motors, dynamos, lamps, leads, &c., amounted to 40,000fr.. The authorities were opposed to this outlay, and contemplated returning this white elephant to the Government, when M. Lalaing came to the rescue, and reduced the share of the town to 20,000fr. This comparatively modest sum will doubtless be voted by the Finance Committee.

At Liége the electric lighting question is again to the fore. M. Tudor, of accumulator fame, has laid a proposal before the authorities for the lighting of the interior of the Hotel de Ville, as well as the steps of the Place du Marché. Accumulators will, of course, be used, and a preliminary trial at M. Tudor's expense is offered. If the scheme is carried out, it will not be the first of its kind, in Belgium at any rate. The commune of Dolhrain has about 100 incandescent lamps, which are run off Tudor accumulators, and which cost 2·5 centimes per lamp per hour, hydraulic power being used.

Some little time ago attempts were made to introduce the Schanschieff battery into this country. In spite of the eulogistic report of two English *savants*, the performance of this battery was by no means brilliant. A proposal was made to one of our leading manufacturers to buy the Schanschieff patents, which are at present owned by an English firm. The offer was, however, declined, and this little transaction has been indefinitely postponed. The report of the Railway and Postal Telegraph Department shows that the electric light is daily coming more and more into vogue in this direction. In 1883 the electric light used only amounted to 6,310 carcels (60,000 candles); in 1887 this figure was almost doubled. The light is, in fact, coming into general use at our large railway stations.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *February* 16, 1889.

The death of the Crown Prince has robbed the Vienna Electro-Technical Society of its patron. Of all the great men in the State none took such an interest in the development of this new science as the Crown Prince. He had been chairman of the Electrical Exhibition in Vienna, and was ever ready to aid and support any movement which had for its object the furtherance of electrical science. To him is due the saying, which has gained much currency, "that soon he hoped to see Vienna at night flooded with light." Hopes are entertained that the Archduke Rainer may be induced to take the lamented Crown Prince's place.

Compared with other countries, there is comparatively little activity in electrical matters in Austria. Apart from the company which is now being promoted by Messrs. Ganz and Co. and the Union Bank, for the purpose of lighting up a part of Vienna, another company is said to be in a fair way of being promoted, with a capital of 2,000,000fl., by Messrs. Siemens and Co., for the same purpose. It is, however, to be feared that the obstructive policy of the Vienna Town Council, may make the success of these two companies very questionable. In telephone matters greater activity prevails. The Vienna Company are connecting up at the rate of 50 to 60 a month. In the other towns worked by the Telephone Company of Austria new subscribers are joining rapidly, and the telegram transmitting service is being used more and more. Trunk lines are being run by the Government. The Vienna-Prague line is now taken in hand seriously, all preliminary work has been done, and the building is to commence in May. The Hungarian Government has also agreed to the connection of Vienna with Pesth, and this line is also to be built this year. In Bohemia eight trunk lines are to be finished, and the Government propose opening new exchanges in Dux, Brux, Aussig Teplitz, and Franzensbad, also in Salzburg.

Mexican Telegraph (Cable) Company.—Advices from the City of Mexico give the following statement for the year ended December 31 last (the last quarter partly estimated):—

	1888.	1887.	Inc. or Dec.
Earnings..	$318,080	$268,166	+$49,914
Expenses..	59,587	58,896	+ 691
Net	$258,493	$209,270	+$49,223

It will be seen that the operating expenses last year were little less than 19 per cent., as against about 22 per cent. in 1887.

CORRESPONDENCE.

TESTING INSULATION RESISTANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your leaderette on this subject in *The Electrician* of February 8th, in which you say:—"Now, apart from the practical inconvenience (amounting, in fact, almost to an impossibility) of bringing the mirror galvanometer into regular use for such a purpose, we are of opinion that the only really valuable test would be one with an E.M.F. considerably higher than that which the insulation will afterwards be subjected to, and, more than this, the current should be kept on the wire for some considerable time." Further, you remark in *The Electrician* of February 15th that I raise the objection that such treatment has a tendency to "break down" an incipient fault. Now, this last remark shows that you have misunderstood me, for I *fully agree with you* that it would be most advisable that every electric light and power installation *before* being accepted or taken off the contractor's hands should be stressed for some considerable time by an E.M.F. not less than the ordinary working E.M.F., and, if possible, with double the normal E.M.F., for the very purpose of developing or breaking down incipient faults, just as boilers and steam pipes are stressed to double their working pressure. Wherein I apparently differ from you is this, that I do *not* consider that it is absolutely necessary, or even advisable, to place delicate accurate testing instruments in direct circuit with these severe stress-ferreting currents. I much prefer to apply the stress current (where possible) by itself, and then *immediately* afterwards test the circuits with my delicate mirror galvanometer, and only an E.M.F. of 10 or 12 volts. I have used nothing else than a Thomson's mirror testing galvanometer, made up for me by White, of Glasgow, to a pattern which I devised when in the Eastern Telegraph Company, as handy for taking from the cable ships to shore in any boat and in any weather, and setting up in any place where a lamp can be got to burn. The little case 15in. high, 7in. wide and broad, contains a galvanometer with three coils, 1,000 ω, 1 ω and ·1 ω, controlling magnet and shunt box, key, lamp and scale complete. It can be set up within five minutes, and packed together in two minutes. By simply turning the mirror tube through 90 degrees, the very delicate cocoon silk suspension is entirely freed from the weight of the mirror, and then the whole apparatus can be handled like an ordinary handbag. I have used it in hundreds of instances, and in some of the most out landish and awkward places, such as stoke-holes, engine rooms, and cabins of ships, cellars, half finished houses and churches (for testing lightning protectors). With one meghom in circuit and one cell it gives a readable deflection. But if such an instrument be objected to for "regular use," anyone can procure the very compact and well-designed electric light lead testing set made by the I. R. and G. P. Company, Silvertown, which measures from ·01 ω up to 9 Ω, wherein the galvanometer consists of a delicate horizontal pivoted needle.

If we were under the necessity of placing in the hands of jointers or assistant electricians a battery of 100 or 200 volts, or a small portable dynamo capable of giving those E.M.F.s *along with* a reliable Wheatstone bridge, resistance coils, and a sufficiently sensitive galvanometer, we should find the apparatus very frequently out of order from fused coils, &c., and then it would soon be considered as a theoretical nuisance.

The application of high E.M.F.s are only necessary for the purpose of "breaking down" or developing an incipient fault. The mere detection of, as well as the position of, a fault can be best ascertained by a comparatively low E.M.F., and a sensitive galvanometer—say, one that will indicate the presence of $\frac{1}{1000000}$th of an ampere—with a few small cells contained in a portable case. Such apparatus is within the reach of and should be used by every one in charge of wiring, or by those who have to test and pass installations. No installation should be passed until tests with such apparatus have been taken *after* the working current has been kept on for some days.

Digitized by Google

Referring to Dr. Waltenhofen's tests of the Vienna Court Theatre, you remark "that the results obtained show a higher constant (K somewhat exceeding 20,000) than any figure which has yet been proposed." My constant, you will remember, is K = 100,000 per lamp, or, say, = 50,000 for every lamp requiring 0·5 ampere, the average current per lamp of the incandescent lamp circuits, as stated by Dr. Waltenhofen. It is curious to note how foreigners bring out well-known British methods of tests and rules under their own names, *e.g.*, the "Uppenborn method" and the "Ross formula." The former is very old, and the latter is simply the rule of the Society of Telegraph-Engineers with the constant doubled. You will have observed that Dr. Waltenhofen tested the various sections with *but* 12 Siemens cells, or, say, 12 or 13 volts, and finally the whole with a 52-cell accumulator battery of, say, 110 volts. He very sensibly, however, avoided putting his Weinholt mirror galvanometer into direct circuit with this higher E.M.F. and the leading wires. His tests have evidently been taken with great care, although with an apparently unnecessary amount of trouble and detail. His description reads as if this job had been his first lesson and rehearsal of insulation resistance testing.

The high average results obtained for such a large installation of 5,300 lamps, and the extraordinary patience and perseverance exhibited by the testers are extremely creditable to both contractors and electricians, and materially add to the stock of knowledge on this most important subject.—Yours, &c.,

ANDREW JAMIESON.

[We are not conscious of having made the suggestion—which our correspondent very properly deprecates—as to putting a mirror galvanometer in circuit with a high E.M.F. As a matter of fact, we said, in so many words, "in this case the galvanometer need not be very sensitive." Our correspondent is, of course, right about the constant.—ED. *E.*]

"PRACTICAL ELECTRICAL MEASUREMENT."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The reviewer of this book is under a misapprehension when he speaks (*The Electrician*, February 15th, page 428) of an error inherent in ohmmeters, viz., the effect of the resistance of the current coil or of the current taken by the pressure coil.

Will you allow me to point out that the scale of an ohmmeter is, or ought to be, started from a zero obtained by coupling the pressure coil in shunt to the current coil alone, and there is therefore no such error as the reviewer imagines. This being so, I have to confess that the "ingenious method of winding" which he very kindly attributes to me is also mythical.—Yours, &c.,

SYDNEY EVERSHED.

THE EFFECTS OF CURRENTS UPON CONDUCTORS; AND THE "MŒNNICH INDICATOR."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Bartlett's letter in your issue of last week draws attention to a point of some little interest not only to the practical electrician but to the scientist. Those who have had much to do with resistances to carry heavy currents will agree with me, I think, in saying that there is an action something like the "fatigue of materials," even though the wire does not become sensibly heated. In my apprenticeship I well remember meeting with a set of resistance coils in circuit with a set of Brockie lamps, and on going to touch them they fell to pieces through brittleness; this, too, without having 'been habitually heated." German silver hardens on coiling into spirals, but the few experiments I had time to make in the beginning of last year seemed to show that it is only when that metal has been coiled in spirals or a helix that on passing a current through it for some time brittleness occurred. A straight wire carefully prepared and coupled up showed no signs of any such action, while a spiral of the same wire and under the action of the current for the same time became brittle. I think Mr. Preece drew attention to a somewhat similar action in copper wire, and he speaks of his difficulty in obtaining "virgin copper" through which one might be certain no current had been passed.

With regard to another matter in your issue of the 15th inst. It is curious how over and over again the same idea is repeated, or repeats itself, in similar forms. About eighteen months ago I had a similar arrangement to the "Mœnnich Indicator," as figured on page 438, at work in my laboratory in the North. I used it between a summer-house and the test room to indicate the changes in length of various materials inserted in the circuit of a battery which was at a distance. My attention had been drawn to this means of transmitting the relative position of a needle and scale; firstly, by a study of the Hughes induction balance, and then by the great attention paid at that time to mutual and self-induction. A scheme very like that shown was the outcome of several days' work at the question of how to transmit the position of the indicator outside to the laboratory, and on fitting up the arrangement it was found to work very well.—Yours, &c.,

CHARLES H. YEAMAN.

London, February 19.

HEMPEN-COVERED CABLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your Notes of last week's issue on "The Theory of Hempen-Covered Submarine Cables finding favour in America" you say: "There are various species of teredo which attack the cables, and some of these marine parasites have a special fancy for hemp."

I have had several years' experience in repairing cables, many of them in waters infested by various species of teredo, and I have yet to learn these borers have a "special fancy" for hemp.

Many cables have been attacked by the teredo, and the sheathing, composed of hemp or Manila with steel or iron wires, have been pierced into the core; but I do not think that is sufficient reason for saying these hempen-covered cables would suffer from the same cause.

During the repair of a cable I once took off two "stoppers," both secured to the cable a few fathoms apart; they had been "slipped" at the final splice years before; one was Manila, the other hemp. The former was riddled with teredo, the latter was nearly as good as the day it was "slipped." The teredo had not pierced it. Evidently they had no "special fancy" for the hemp in that case.

Some of these hempen-covered cables have been lying in Halifax (N.S.) harbour in use for several years, and have not required repair, although the bottom is infested with the teredo. These cables have been lifted and examined several times, with the result that shows the teredo has not yet learnt to "fancy" them.—Yours, &c.,

W. R. LUGAR.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

January 28, 1889.

1,500. R. M. Presland (London) and E. H. Glover (Walthamstow). Applying electric light to cycles.
1,510. W. M. Mordey. London. Improvements in electrical transformers.
1,535. J. A. Timmis. London. Improvements in the construction and working of dynamos.
1,537. A. J. Boult. London. Improvements in or relating to electric incandescent lighting (S. Doubrava, Austria).

January 29, 1889.

1,573. C. U. Fisher. London. Certain improvements in electro-magnetic transmitters (port electrics) (J. T. Williams, United States).
1,611. M. W. Dewey. London. Improvements relating to multiplex electric telegraphy.

January 30, 1889.

1,673. G. Philippart. London. Improvements in the construction of secondary batteries.
1,677. G. H. Whittingham. London. An automatic electric switch.

January 31, 1889.

1,757. J. Mason. London. A new or improved automatic coin-freed machine for giving electric shocks.
1,768. P. Von Hertling. London. Automatic circuit changer for electric currents.
1,775. M. R. Ward. London. Means and appliances for holding electric accumulators on vehicles.

February 1, 1889.

1,823. A. Coleman and H. F. Jackson. London. Improvements constituting a combined translator and indicator for telephonic purposes, part of such improvements being applicable also, either in such combination or otherwise, for preventing or lessening induction between translators placed near together.
1,827. M. Salmony. London. Improvements in telephones.
1,839. C. Wells. London. A combination electric arc light.
1,846. W. Boggett. London. Improvements in the application of heat produced from liquid hydro-carbon and water burners to the production of light and electricity, and in apparatus for this purpose.
1,850. W. T. Goolden and H. W. Ravenshaw. London. Improvements in the method of constructing the armatures of dynamo-electric generators and motors.

February 2, 1889.

1,855. H. Hobson, S. Rushton and A. Wood. Manchester. An improvement in insulators and appliances for fixing, tightening and retaining telegraph wires, electric wires, and other wires or ropes.
1,861. W. J. S. Barber-Starkey. Manchester. Improvements in and connected with galvanic batteries.
1,865. J. Bushell and G. W. Hughes. Liverpool. Improvements in telephone apparatus to be designated as a telephone receiver rest.
1,892. A. J. Boult. London. Improvements in electric motors and means for regulating the same (L. W. Serrell and H. L. Lufkin, United States).
1,903. S. Ziani de Ferranti. London. Improvements in electric motors and electric meters.
1,904. S. Ziani de Ferranti and F. Ince. London Improvements in dynamos suitable especially for use as motors.

February 4, 1889

1,856. J. H. Woodward, E. S. G. Rees. Manchester. Improvements in the method of and means for the regulation of dynamos.
1,961. R. H. Courtenay. London. Improvements in microphone apparatus for increasing and transmitting sounds by means of earth currents, also by means of chemical batteries.
2,003. A. L. Shephard. London. Improvements in electric regulating apparatus for use in connection with steam engines and other motors and dynamo electric machines.
2,006. H. H. Lake. London. Improvements in apparatus for receiving payments and permitting the administration of electricity in exchange therefor (D. R. Johnston, Belgium).

February 5, 1889.

2,044. C. H. W. Stielow. London. An improved type-writer and telegraphic apparatus applicable in combination therewith.
2,056. R. Wellens. London. Improvements in electric stop valves.
2,066. L. Paget. London. Improvements in the manufacture of electrodes for secondary batteries or accumulators.
2,071. A. B. Ferdinand. London. Improvements in electric systems.
2,079. A. H. Norman. London. An improvement in plates for secondary voltaic batteries.
2,080. H. H. Lake. London. Improvements in and relating to portable electric batteries and in electrodes therefor (L. T. Stanley, United States).
2,082. W. P. Thompson. Liverpool. Improvements in or relating to telephone call-boxes (A. Griffith, H. A. Burbank and W. H. Jordan, United States).

February 6, 1889.

2,137. E. Gwosdeff. London. Improvements relating to magnetic telephony.
2,141. C. Baur. London. An electric meter.
2,145. W. Green. London. An improved electrical apparatus for lighting cigars or pipes, and for other purposes.
2,151. W. J. Woodward and F. H. Judson. London. Improvements relating to electric batteries.

February 7, 1889.

2,168. W. P. Thompson. Liverpool. Improvements in or appertaining to electric meters (H. O. Tudor, Luxemburg).
2,169. W. P. Thompson. Liverpool. Improvements in or relating to electric signalling apparatus for railways (E. J. Jérome de Baillehache, France).
2,176. F. L. Rawson. London. Improvements in materials and methods of preparing the same for bases of electrical instruments and for other electrical purposes.
2,199. A. Douglas and F. Smith. London. Improved electric periodical contact-making switch.
2,231. C. Adams-Randall and W. H. Cook. London. Electric fog and danger signalling apparatus for railways.

February 8, 1889.

2,243. W. Andrews. Nottingham. Electrical connections attached to railway locomotives and to connect to a metal plate affixed near the rail, arranged by a metal wire brush.
2,276. E. Guitton. London. Improvements in the construction and arrangement of primary batteries (M. Sappey, France).
2,297. C. Smith. London. Improvements in primary and secondary transportable galvanic dry elements (W. L. F. Hellesen, Denmark).
2,299. L. A. W. Desruelles and R. F. O. Chauvin. London. Improvements in apparatus for measuring electric currents.

February 9, 1889.

2,313. H. N. Lawrence. London. Improvements in means of applying electricity for therapeutic purposes.
2,331. W. H. Dowland and W. Mills. London. An improved apparatus for economically effecting the double decomposition of certain substances by the aid of electricity.
2,349. T. H. White. London. Improvements in and relating to electric appliances for illuminating the dials of electric clocks and watches.

February 11, 1889.

2,375. S. B. Wilkins. Edinburgh. Improvements in the construction of telephones.
2,406. J. Roper. Huddersfield. Improvements in the mechanism of electric arc lamps.
2,407. A. Bernstein. London. Improvements in dynamo electric machines.
2,413. J. E. Wright and J. Moore. London. Improvements in printing telegraphs.

February 12, 1889.

2,472. W. L. Wise. London. Improvements in secondary batteries and plates or elements therefor (The Gibson Electric Co. of Europe, France).
2,476. S. Sudworth. London. An improved electrical alarm.
2,480. H. H. Lake. London. Improvements in and relating to apparatus for measuring electric currents (H. H. Cutler, United States).

February 13, 1889.

2,536. T. W. Watson and A. H. Watson. London. Lighting cigars, pipes, &c., by electricity.
2,544. A. Douglass and F. Smith. London. Improvements in the form and manufacture of secondary battery frames and plates.
2,567. P. B. Elwell and J. K. Starley. London. Improved means and apparatus for electrically driving vehicles.

February 14, 1889.

2,614. J. Oulton and J. Edmondson. Halifax. Improvements in electric meters.
2,628. M. Stuhl, J. M. Lautensläger and F. Lautensläger. London. Improvements in electric contact and alarm thermometers.
2,642. G. Forbes. London. Improvements in dynamo electric machines.
2,646. W. H. Scott and L. Paris and Scott. London. Improvements in apparatus or means for metering electric currents.

February 15, 1889.

2,674. H. J. Peddie. Edinburgh. Apparatus for signalling in mines and coal pits, and on railways and elsewhere, and for stopping the winding or hauling steam engines when such signals are given, and for causing intermittent currents of electricity or magnetism for any required purpose.
2,694. W. S. Goolden and S. Evershed. London. Improvements in apparatus for the measurement of electrical resistances.

COMPANIES' MEETINGS & REPORTS.

Submarine Telegraph Company (Limited).

Report of the Directors to be submitted at the meeting of the proprietors of this Company, to be held at the Offices of the Company, 2, Throgmorton-avenue, London-wall, E.C., on Tuesday, the 26th inst., at one o'clock :—

The accounts for the six months ended 31st December, 1888, show a net sum which enables the Directors to add the usual proportion of the receipts to the reserve fund, to recommend a dividend for the half year at the rate of 16 per cent. per annum, and to carry over a balance of £628. 19s. 3d. The dividend paid for the corresponding period of 1887 was at the rate of 15½ per cent. per annum.

The number of messages transmitted during the six months was 1,846,002 containing 20,328,271 words. In 1887 there were transmitted 1,695,860 messages containing 18,701,557 words. The average length of messages in 1888 was 11·01 words against 11·03 words in 1887.

The receipts of the half-year show an increase of £3,886. 13s. 4½d. over those of 1887, and the expenses show an increase of £1,283. 6s. 6d. This increase is principally caused by the insertion of much new cable when repairing several of the cables interrupted in the half-year, and by the thorough overhaul and repair of the steamer in the first six months of 1888, to which reference was made in the last report of the Directors. The proprietors were then informed that only £500 of the cost was charged in the accounts for June, 1888, and that the balance, £407. 14s. 9d. would be charged in the accounts of the present half-year.

The proprietors are no doubt aware that the Company's concessions and agreements with the Postmaster-General and with the foreign Governments expired on the 12th January, 1889. The Directors have to report that the respective Governments agreed to allow the Company to continue working their own cables, as well as those belonging to Her Majesty's Government until 31st March, 1889.

No arrangement has yet been definitely arrived at between the Directors and the Government for the acquisition of the Company's property, but considerable progress has been made, and as the Government has decided to take over the property on the 1st April, the matter cannot be much longer delayed. The Directors would have been glad to submit for the consideration of this meeting definite terms of agreement with the Government, but at the date of this report they are unable to do so.

Telegraph Construction and Maintenance Company (Limited).

Report of the Directors to be submitted to the members at the twenty-fifth ordinary meeting to be held at the offices of the Company, 38, Old Broad-street, London, E.C., on Tuesday, the 26th inst., at one o'clock :—

2. The accounts for the year show a net profit of £82,580. 3s. 6d. after charging the interest on the debentures. To this sum must be added £50,436. 10s. 10d. brought forward from last year, making a total of £133,016. 14s. 4d. From this amount is deducted the interim dividend of 5 per cent., paid July 17th, 1888, amounting to £22,410, leaving £110,606. 14s. 4d. to be dealt with. Of this sum the Directors propose to distribute a dividend of £1. 16s. per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2. 8s. per share, or 20 per cent., free of income tax, leaving £43,376. 14s. 4d. to be carried forward to the next account.

3. During the past year the cable factories at Greenwich and the gutta-percha department at Wharf Road have been fairly employed. A length of about 6,000 miles of telegraph wire has been insulated, including submarine and land lines.

The Company's steamships have laid cables between the Dutch Possessions in the Eastern Seas, and at the present time are engaged triplicating a portion of the Eastern Extension Telegraph Company's system to Australia.

Various repairs have been made in cables in the North Sea and in the Brazilian line between Madeira and St. Vincent ; and the Direct United States Company's Atlantic Cable has been placed in good working condition, repairs having been effected at a maximum depth of 2,200 fathoms.

4. The charter of the steamship "Kangaroo" to the Italian Government for distilling purposes in the Red Sea continued up to the end of May, and the Company have since disposed of her.

The steamship "Calabria" has been on charter since November last.

5. The Company's works at East Greenwich and Wharf Road are in efficient working order.

6. It is with regret that the Directors have to announce the death of their late colleague, Lord Alfred Paget. They have elected to fill his place Mr. William Shuter, who has held an important and responsible position in the Company since its formation.

7. The £150,000 Six per Cent. Debentures have been replaced by the issue of a like amount, bearing interest at 5 per cent. for a period of five years from the 1st January, 1889.

8. The retiring Director is Mr. George William Campbell, who, being eligible, offers himself for re-election.

9. The meeting will have to appoint auditors for the ensuing year. Mr. John Gane (Messrs. Gane and Jackson) and Mr. James Glegg (Messrs. Quilter, Welton and Co.), who retire, offer themselves for re-election.

The Brighton and Hove Electric Light Company (Limited).

Report of the Directors to the fourth ordinary general meeting of the Company, to be held at the offices of the Company, Gloucester-road, Brighton, on Tuesday, February 26th next :—

1. The Directors have pleasure in submitting to the shareholders the report of the operations of the Company from the 1st January to the 31st December, 1888.

2. The capital account has during this period been augmented by the sum of £3,100, which has enabled the Company to increase the capacity of its plant and to extend and re-arrange the circuits. The profit and loss account, after writing off an ample sum for depreciation of plant (which has, however, been kept in thorough repair out of revenue), shows a balance of profit for the year of £532. 12s. 9d., which, with the balance brought

forward from last year's accounts, makes the sum to the credit of profit and loss account £603. 0s. 8d., and the Directors recommend the following appropriation of it :—

Dividend of 5 per cent. per annum on the share capital	£574 11 10
Carried forward to next year's profit and loss account	28 8 10
	£603 0 8

3. There has been a steady increase in the Company's business during the past year. The mains belonging to the Company now extend a distance of *over twenty miles* ; reaching westward as far as King's Garden, Hove ; eastward as far as Belgrave Place, Kemp Town ; and northward as far as Hanover Crescent, Lewes Road.

4. At the beginning of the year, in deference to a very general request, the Company arranged to run the machinery day and night, and though this has added considerably to the cost of working, it has given great satisfaction to the customers.

5. With the view also of placing the electric light within the reach of an extended number of customers, the Company has adopted a sliding scale of charge, which gives the consumer the benefit of a considerable reduction in price. This reduction came into operation on the 1st of January this year.

6. During the past year the Company has almost entirely transformed its method of supply, and replaced the old multiple series system with the converter system, by means of which it is possible to turn off lamps singly, instead of in groups, as hitherto. These changes have largely increased the number of the Company's customers.

7. The exact nature of the improvement in the Company's business may be seen by the following statements :—(*a*) Lamps supplied from the Company's mains on December 31st, 1887, equivalent to 2,970 10 candle-power lamps ; December 31st, 1888, equivalent to 5,500 10 candle-power lamps. (*b*) Quantities of electricity supplied from the works during the past year, as compared with corresponding months of previous year :—

	Units supplied. 1887.	1888.	Percentage of increase.
January	5,960	7,533	43 per cent.
February	3,865	5,430	40 „
March	3,444	4,550	32 „
April	3,188	4,813	51 „
May	2,180	3,359	54 „

November	7,512	12,567	74 „
December	8,738	13,930	60 „
Totals for the 12 months	52,918	74,910	41 „

8. During the past year the Board of Trade have represented to the Company the advisability of applying for statutory powers, in order to enable it to change its method of distribution by means of overhead wires to a system of underground mains ; and in view of the increasing demands for the electric light in Brighton and Hove, and the necessity of laying cables underground in order to cope with a large business, the Company made application in November last for a Provisional Order under the Electric Lighting Acts, 1882 and 1888, and this Provisional Order is at present being considered by the Board of Trade.

9. The Company has given a pledge to the Brighton Corporation and the Hove Commissioners to largely increase its works in the event of the Provisional Order being granted, and the necessary formal meetings have been held to sanction the raising of the nominal capital of the Company from £25,000 to £100,000, and the change of the name of the Company from the Brighton Electric Light Company (Limited) to the Brighton and Hove Electric Light Company (Limited).

10. When the Directors deem the time opportune, the shareholders will be called together and consulted with regard to further plans for the extension of the Company's operations.

12. Mr. Arthur Wright, who has brought the works to their present state of efficiency, has continued to act as Managing Director ; and the thanks of the shareholders are due to him for the highly satisfactory manner in which he has conducted the business of the Company during the past year. He reports that the engines and dynamos have continued to give satisfaction, and are at the present time in thoroughly good working order.

13. During the past year, Mr. William Smithett, one of the Directors of the Company, has resigned his seat on the Board in consequence of his leaving Brighton, and his place has been filled up by Mr. Thomas Webber Jerrard. The Board has also been strengthened by the election of Mr. Philip Arderne Latham. The retiring Directors are Mr. Robert Hammond, Chairman, and Mr. Arthur Wright, Managing Director, who offer themselves for re-election.

14. The meeting will have to elect an auditor or auditors for the ensuing year.

NEW COMPANIES REGISTERED.

GRAPHOPHONE SYNDICATE (LIMITED).—This syndicate was registered on the 14th inst., with a capital of £100,000 in £10 shares, to acquire seven British patents taken out by Bell and Tainter, with application for others now pending, relating to the reproduction of sound, upon terms of two provisional agreements dated 31st ult., the first between Woodhouse and Rawson (Limited) and J. H. Ward, and the second between Walter T. Glover and Company and J. H. Ward ; and to carry on business as engineers and electricians. The subscribers, with one share each, are :—F. L. Rawson, 11, Queen Victoria-street, electrical engineer ; J. H. Ward, 55, Shelgate-road, Wandsworth ; J. C. St. Quentin, 38, Lee-road, S.E. ; J. McFarlan, Invermay, Wimbledon ; Sir R. W. Rawson, 68, Cornwall-gardens, W. ; Sir F. Leopold McClintock, 8, Atherstone-terrace, S.W. ; G. Offord, Putehill Villa, Sydenham. The subscribers are to appoint the first directors ; qualification, 100 shares ; the company in general meeting will determine remuneration.

MINES AND GENERAL TELPHER COMPANY (LIMITED).—This company was registered on the 15th inst., with a capital of £4,000, in £1 shares, to construct and work lines for the carriage of minerals and other materials, under a license from the United Electrical Engineering Company (Limited.)

SUNDERLAND AND DISTRICT ELECTRICITY SUPPLY COMPANY (LIMITED).—This company was registered on the 13th inst., with a capital of £100,000 in £5 shares, to generate, distribute, and supply electricity for lighting, heating, motive power and other purposes. The number of directors is not to be less than four, nor more than nine ; qualification, 100 ordinary shares, or £500 stock ; the subscribers are to appoint the first ; remuneration, £250 per annum, and one-tenth of the annual profits of each year (except the amount carried to reserve) over £7 per cent. per annum, provided that £1,000 per annum be the maximum remuneration.

CITY NOTES, &c.

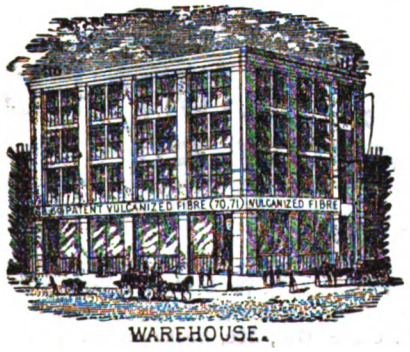
BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this company for the week ended February 15 amounted to £5,346.

LONDON ELECTRIC SUPPLY CORPORATION.—The directors of the London Electric Supply Corporation (Limited) offer for subscription £250,000 preference capital, in 50,000 shares of £5 each. Under the resolutions creating these shares, holders have the option, on or before December 31, 1895, of converting their shares, when fully paid up, into ordinary shares of the corporation. The corporation was formed in August, 1887, to purchase the undertaking of Sir Coutts Lindsay and Co. (Limited), which company had for three years previously carried on an electric lighting business at the Grosvenor Gallery, New Bond-street, W., and to develop and extend the same. It is estimated that the net profit, after providing for depreciation, will amount to £60,000 per annum, upon which the interest on the preference shares now offered for subscription, amounting to £15,000 per annum, will be a first charge. The list of applications for shares closed at noon on Tuesday last.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended February 15th, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,506.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this company for the half-month ended February 15 amounted to £3,046, as compared with £3,424 last year, being a decrease of £378.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,
PATENTED.

This new material is supplied in two qualities, Flexible and Hard.
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.
It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.
The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.
Sold in sheets, 5ft. 6in. by 2ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

ENDLESS TELEGRAPH PAPERS.

(As supplied by Waterlow and Sons, Limited, to Her Majesty's Postal Telegraphs.)

These Papers are kept in stock in large quantities, and can be cut to any width for the **MORSE, WHEATSTONE, HUGHES,** and other machines; also the **RECORDER** Printing Paper, as used on the various Electric Automatic Printing Instruments.

COLLOTYPE PRINTING.

High-class Reproductions in Facsimile of Monochrome Drawings, &c., specially useful for the Illustration of Trade Catalogues.

PHOTO-INTAGLIO ENGRAVING ON COPPER; PHOTO-ZINC ETCHED BLOCKS.

Photo-Lithography and Photo-Engraving and Printing in all its branches.

WATERLOW & SONS, LIMITED,

27, GREAT WINCHESTER STREET, LONDON, E.C.

VULCANITE

SHEETS, RODS, TUBES, CELLS, &c., for Electrical Purposes,
MANUFACTURED BY
THE NORTH BRITISH RUBBER CO., LIMITED.
EDINBURGH; LONDON, 57, Moorgate-st.; MANCHESTER, 6, Charlotte-st.; LIVERPOOL, Cereal-court; GLASGOW, 106, Buchanan-street.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 563.—Vol. XXII. FRIDAY, MARCH 1, 1889. Price Fourpence.

NOTES.

At a special meeting of the Commissioners of Sewers, held on Tuesday last, the report of the Streets Committee on Electric Lighting, which appeared in our issue of February 8th, was finally adopted, and tenders will be invited forthwith on the basis of the conditions therein set forth. An amendment moved by Mr. C. T. Harris was, however, only rejected by a majority of one vote. Mr. Harris's proposal was to the effect that nothing should be done until certain Companies, which he proceeded to name, had obtained Provisional Orders for the City district. If this suggestion had been adopted, not only would it have entailed another long delay, but it is obvious that it would practically have put the Commissioners almost at the mercy of the Companies who had obtained Provisional Orders.

The following paragraph appeared in the *Financial News* of the 22nd ult. with reference to telegraphic communication with South Africa :—

> There has been no cable communication with Johannesburg for the past week, the line being out of order. This interruption of communication has not only caused serious annoyance in the South African markets, it has also led to a movement for laying a new cable. Some of the most influential men identified with the Witwatersrand district are behind it, and we learn that the capital has already been offered five times over.

In reply to the above Sir James Anderson writes to the *Financial News* as follows :—

> The Eastern and South African Telegraph Co.,
> 50, Old Broad-street, London, E.C.,
> 22nd February, 1889.
>
> Sir : In your issue of to-day I notice a paragraph to the effect that the cable communication to Johannesburg has been interrupted, and that this has led to a movement for laying a new cable.
>
> Will you permit me to say there has been no interruption of the cable communication whatever, neither have the South African land lines been interrupted as far as the Transvaal. The whole of the interruption, so far as we know here, has been within the Transvaal itself.
>
> The inconvenience of this interruption has been represented to the Transvaal Government in every possible way, and at present communication is again restored.
>
> Efforts are being made to improve the land service upon all the South African lines. I may also state the ships of the Telegraph Construction and Maintenance Company, and the India-Rubber, Gutta-Percha and Telegraph Works Company will sail from London on the 8th March next, to lay an alternate line on the West Coast down to the Cape of Good Hope direct.—Yours truly,
>
> (Signed) James Anderson, Managing Director.

As a sample of the unreasoning animus which some sections of the Press thoughtlessly throw into their remarks upon submarine cable companies, the paragraph from the *Financial News*, which we reprint above, is in its way quite unique. As a matter of fact, there is no cable to Johannesburg, which is a town in the extreme North of the Transvaal 350 miles inland from the cable terminus at Durban. The real cause of dissatisfaction is the inadequacy of the land line to meet the overwhelming pressure of traffic consequent upon the gold rush which has recently set in and the breakdown of many of the operators through overwork. Numbers of telegraph operators are, however, hastening to the Transvaal and Cape Colony, and additional lines are being erected. Until the service is reorganised, therefore, the public must submit with what patience it may to the inconvenience caused by delays and errors. The correspondent of the *Financial News* is evidently unaware of the above, as also of the fact, to which we further allude below, that an alternative line of cable communication to South Africa is on the point of being laid down. Perhaps, however, the oddest statement to which our contemporary commits itself is that the capital for a new cable has been subscribed five times over in the Witwatersrand district. Seeing that a cable such as is spoken of would cost three or four millions sterling, the district referred to must be a perfect El Dorado.

The report of the twenty-fifth annual meeting of the Telegraph Construction and Maintenance Company, published by us this week, furnishes a striking commentary on some recent complaints as to the dilatoriness of cable companies in supplying adequate means of communication with our Colonial Empire. The Telegraph Construction and Maintenance Company, besides effecting several important repairs and extensions, have within the past twelve months constructed and laid a 1,000-mile triplicate cable connecting Western Australia with Java, an operation the successful accomplishment of which was announced on Tuesday last. Another line of 456 miles has been submerged between Java and Moluccas. They have also already manufactured the greater portion of the 1,530 miles of cable required to complete the West African system, and a vessel will sail with it at the beginning of next week. When this operation has been carried out Africa—with the exception of the coast between Cape Town and Durban, which is provided with land lines—will then be surrounded by submarine cables on all sides, east and west, and on the Mediterranean.

On first hearing that Mr. Crompton had recommended the use of alternating transformers at Harrow, one is inclined to exclaim, "Is Saul also amongst the Prophets?" And on reading further the report of the meeting as it appears in the

Digitized by Google

Harrow Gazette and one of our weekly contemporaries, it would, moreover, be natural to conclude that he had prophesied with all the characteristic enthusiasm of the new convert. A letter from Mr. CROMPTON, which will be found amongst our correspondence, puts, however, a different complexion on the affair. It will be seen that Mr. CROMPTON denies that his general preference for battery transformers has been shaken during the period which has elapsed since he read a Paper on the subject before the Telegraph-Engineers. In replying to the discussion on that Paper, moreover, he acknowledged that in certain districts the alternator might even possess a distinct advantage over the battery (see *The Electrician*, May 25, 1888, p. 89). Such a district he has found at Harrow.

MR. CROMPTON appears also to have been the victim of another misconception, although, unless the reports are again lamentably incomplete, he failed to set himself right upon this point, even when directly challenged to do so. In quoting a sum "not exceeding £6,000" as the cost of central station and distributing plant for the supply of 3,000 lamps, it is impossible to suppose that he could have referred to lamps of more than eight candle-power, and even then the estimate seems remarkably low. But when asked by an electrician present (Mr. W. F. TAYLOR) how the present quotation of £2 per lamp could be reconciled with the estimate of £5. 14s. per lamp [of 50 watts] in his Paper of April last, Mr. CROMPTON is reported to have said that the difference arose from the additional cost of laying underground mains in London as compared with the provinces. The explanation is so obviously inadequate that, whether Mr. CROMPTON did or did not content himself with it, we have no doubt in our own mind that the discrepancy arose in the way above suggested. The incident affords a pertinent illustration of the confusion arising from the use of the term "lamp" as a unit of power. We hope that Mr. PREECE's definition will be adopted that, unless otherwise specified, a "lamp" means a lamp of 50 watts.

FROM the report of the same meeting in the *Harrow Gazette* we quote the following passage, which will be read with some interest:—

> Mr. PITCAIRN: Is not the alternating system dangerous under any circumstances?
>
> Mr. CROMPTON: No; competition has given rise to the statement, but it is absolutely untrue.

Mr. CROMPTON was no doubt able to make this statement with a clear conscience, but coming from such a source the testimony will doubtless be valued by the advocates of the alternator.

AT the Physical Society on Saturday last Prof. AYRTON exhibited for the first time the long-promised low-reading voltmeter for commercial use. Next week we shall describe and illustrate the instrument in detail. Meanwhile, we may mention that the dial of the instrument reading up to 2·5 volts is about 6in. diameter, and is graduated in hundredths of a volt; the reading being proportionate right round the scale. To show the delicacy of the instrument, Prof. AYRTON made the simple experiment of taking the internal resistance of a secondary cell, by reading the volts (1) on open circuit, and (2) when a known current (of 10 amperes) was passing. The advantage of a trustworthy and portable instrument capable of taking accurate measurements of this class will be patent to every electrical engineer.

WE understand Prof. AYRTON will take an early opportunity (probably at the meeting of the Civil Engineers on Tuesday next), to give a preliminary account of the tests which have been carried out at the Central Institution on the Tesla Motor. On another page will be found a diagram of the windings of the motor, which is now published for the first time.

THE *Electrotechnische Rundschau* in a recent number discusses the "line of economical demarcation" between isolated lighting plant and central station service. It is, of course, obvious that the limit is a very variable one, depending not merely on the cost of power compared with the central station tariff, and upon the size of the installation and the hours of lighting, but chiefly upon the value set by the consumer on the trouble and possible nuisance of having machinery on his premises. At the same time the question is one which, in the case of large and important buildings, may be expected in future often to arise. Moreover, there are some consulting electricians who hold that in favourable circumstances the limit in point of size is arrived at much sooner than is usually supposed. Nevertheless, we do not believe that any one in this country will place the limit anything like as low as, according to the above authority, it stands in Germany. Our contemporary calculates the annual cost of a private installation of 50 lamps of 16 candles, worked by steam power, and burning 2,000 hours per annum, at £100, excluding interest on capital outlay. Taking the Central Station tariff at four pfennings (say ½d.) per lamp hour, and adding cost of lamp renewals, and rent of meter, the cost of 2,000 lamp-hours is £184. So that in Germany it appears that only installations of comparatively small size can afford a central station service.

THE evidence of Mr. C. F. BRUSH, taken on Commission in Cleveland, Ohio, in the action of King, Brown v. The Anglo-American Brush Company, will be found on another page.

THAT electricity might in some way be employed to hasten the process of tanning is one of those ideas which has been "in the air" for a long while. Amongst our "Scandinavian Notes" (*Electrician*, November 9th, 1888) will be found a reference to a method already in use in Sweden which is said to give results of the most satisfactory character. More recently we hear on very good authority that a process of the same kind now at work in Paris produces leather of excellent quality from the raw hide *in four days*. The importance of this new field for the application of electricity is too obvious to need comment.

THE electric motor has been put to many strange uses, from blacking boots to driving dentists' lathes, but we doubt if this

Digitized by Google

long-suffering machine ever found itself in a more novel or more trying position than was recently the case at Toronto. We cannot do better than quote our correspondent, Mr. H. E. DOLAN'S, own words :—"I enclose a cutting from the *Empire* of Toronto, describing the use of the road for the first funeral on Sunday, 17th. On that occasion I drove a motor car, which towed another, both full, and although we were about 3¼ miles from the power station, and had four other cars close behind, all taking as much current as they could, I got my cars up the bridge incline at about 3½ miles per hour, without distressing the motor in the least." After this there is nothing left for us but to agree with the remark of the *Empire* of Toronto, that "a funeral *cortége* consisting in part of street cars driven by electric motors is somewhat of a novelty, even in this age of progress." We should mention that the funeral was that of an Oddfellow.

FOR child-like simplicity and infantile excitement the well-known babe who cried to "see the wheels go wound" is not in it in comparison with the London reporter of the *New York Herald* who took a trip last week on the electrical omnibus. For two columns and a-half he drivels on in this style :—"It spun down the Haymarket from its native lair in James-street like a barrel hoop down a toboggan shoot ; it whisked over the broad plazza of Trafalgar-square, and sped away like a summer zephyr in quest of Blackfriars-bridge. Then it took in the City, and brushed past the Mansion House like a stray comet on the war-path. . . . The voyage was a procession from beginning to end, a journey throughout whose tortuous length the 'bus was moving through a pageant of glory entirely of its own manufacture." MR. RADCLIFFE WARD may well pray for deliverance from his friends. Meanwhile, he may be congratulated on the immunity from serious accident with which his trips have hitherto been associated. It will, however, require a good many such excursions before he will be in a position to publish an authenticated statement of the economical results.

Melbourne Exhibition Award.—We are glad to learn that the Woodhouse and Rawson Electric Supply Company have received a "First Award" at the Melbourne Exhibition.

Rotherhithe Vestry.—At a meeting of this Vestry, last week, it was agreed to support the proposals of the London Electric Supply Corporation, subject to certain objections raised by the Vestry.

Galway.—It will be seen by our advertisement columns that the Galway Town Improvement Commissioners are inviting tenders for the public lighting of that town by gas or electricity.

St. Martin's-in-the-Fields Vestry.—At a special meeting of this Vestry, last week, a resolution was passed approving the application made by the London Electric Supply Corporation for a Provisional Order for this district.

The Hague.—The Hague Tramway Company have just obtained a concession from the Dutch Government for an electric tramway running between Schevening and the Hague. The current will be generated at a central station near Schevening.

Important Sale of Electrical Plant.—The important sale of dynamos, lamps, cables, and other electrical fittings, which we announced in our issue of February 15th, will take place on Wednesday, March 13th. Further particulars will be found in our advertisement columns.

Electric Tramway for Naples.—The *Bolletino delle Finanze* says that an Italian firm of engineers has made a proposal to the municipal authorities of Naples for the establishment of an electric tramway. The concession asked for comprises five lines, having an aggregate length of 14·7 kilometres.

The Lake District.—Steps are being taken to form an electric light company at Keswick, the project having the support of several influential residents. A survey has been made, and it is expected that motive power will be obtained from the River Greta. A prospectus will be issued to the public shortly.

Institution of Electrical Engineers, Students' Meeting.—A meeting was held on Friday, February 22nd, at 8 p.m., Mr. J. Rance, jun., A.I.E.E., in the chair. A Paper was read on "Ship Lighting and the Aspects of Electrical Industries in the Colonies," by Mr. H. W. Handcock, which occupied the whole evening. A discussion upon it will take place on Friday, March 8th.

St. George's (Southwark) Vestry.—The usual fortnightly meeting of this Vestry last week was made a special one for the purpose of considering the recommendation of the Roads Committee, "That this Vestry assent to the granting of a Provisional Order by the Board of Trade to the House-to-House Electric Lighting Company to supply electricity within the parish." The recommendation was carried unanimously.

Newcastle.—At a meeting of the Newcastle City Council on Wednesday in last week, the Town Improvement Committee presented their report relative to the applications for consent to Licenses to supply electricity in Newcastle. The committee recommend that the proposed Licenses of the Newcastle Electric Supply Company and of the Newcastle and District Electric Lighting Company should be supported. The report will be considered at a special meeting of the Council on March 6th.

Galway.—The secretary of the Galway Electric Company writes as follows :—"At a ball recently given by the Royal Welsh Fusiliers at the Courthouse, Galway, to commemorate the fall of Coomassie, we lit the entire suite of rooms by incandescent lamps, including ball room, supper and refreshment rooms, entrance hall, and ante room. The Courthouse was temporarily connected with our central station, which is now approaching completion, and part of which is already working."

The Electric Light in the Emperor's Palace at Pekin.—The Emperor of China intends to introduce the electric light into his palace, for which purpose an engineer from the firm of Siemens and Halske, of Berlin, recently arrived at Pekin with the necessary material. The installation was to be completed before the Imperial wedding, which has just taken place. The installation had to be erected and tried in another place in order to ascertain whether the electric light is not imbued with a "supernatural power."

Holborn Board of Works.—At a general meeting of the Holborn Board of Works on Monday evening last week, the Committee of Works reported that they had had under consideration applications from the London Electric Supply Corporation and the Metropolitan Electric Supply Company for permission to apply to the Board of Trade for Provisional Orders. They recommended that permission be granted the House-to-House Electric Company, who wrote asking for sanction to an application for a License. The application was granted.

Bath.—At a meeting of the Bath Town Council last week, the following resolution, proposed by Mr. Jolly, was carried *nem. con.* :—"That it is desirable in the interests of the public to have the electric lamps supplied by means of underground instead of overhead wires, and that it be referred to the Electric Lighting Committee to so far vary the present contract with Mr. Massingham as to supply the area by means of underground wires, at the price of £25. 17s. 6d. per annum per lamp, and to allow a period of twelve months instead of six months for the completion of the electric lighting, and such other alterations as may be necessary in the contract.

Madrid.—With the exception of the plant in the Italian Opera House (says *Industries*), the isolated electric light installations at the Madrid theatres are going on unsatisfac-

Digitized by Google

torily. In consequence, fresh efforts are being made to establish a large central station in this city, and it appears that there is some chance of this being now carried out, as the local authorities are giving their assistance to the scheme. Major Cabanyes, of the Artillery, is to be entrusted with the technical management of the installation, which has been promoted by Belgian capitalists. No electrical details have yet been made known.

Indo-Persian Telegraphs.—Colonel Sir R. Murdoch Smith, Director of the Museum of Science and Art in Edinburgh, has laid before the Royal Scottish Geographical Society a history of the Indo-Persian Telegraphs, in the construction of which he played so important a part. He stated that, twenty-one years ago, when the overland wire for Indo-European messages was proposed (which was completed in 1870), the expectation was that a message would eventually be got through in a period not exceeding three days. At present the time occupied by a message from the United Kingdom to any part of India, from handing in to delivery, does not exceed an hour and a-half.

Strand District Board of Works.—At a meeting of this Board on Wednesday evening, last week, the Lighting Committee brought up a long report dealing with the proposals for the lighting of the district by electricity. The first portion of it dealt with applications on behalf of the Electrical Power Storage Company and Messrs. Coerber for consent to obtain Provisional Orders. Both of these the committee recommended should be refused. The committee, on the other hand, recommended that the seal of the Board should be affixed to the agreement with the Metropolitan Electric Supply Company. After a short discussion, the recommendations were agreed to unanimously.

Electric Lighting and the Indian Government.—The Government of India has issued a set of 49 rules to be observed in the erection of electric lighting installations. Objection may be taken to any part by anyone interested up to the 1st May. Speaking without special knowledge of local requirements, we should say that while there is little or nothing specifically objectionable in the rules taken individually, yet they are far too numerous and too detailed. Experience has shown that it is frequently impossible to comply with a cut-and-dried set of regulations which profess to order all the minutiæ of the work. It would be much better to lay down a few general rules and leave the rest to the fire insurance offices, with a general right of veto when good cause arises.

New Triplicate Java-Australian Cable.—It will be remembered that some time ago, on more than one occasion, owing in one instance to submarine volcanic action and in the other to the accidental interruption of one cable while the ship was grappling for the other, which was interrupted, Australia was cut off from telegraphic communication with the rest of the world. With great promptitude the directors of the Eastern Extension, Australasia, and China Telegraph Company (Limited) announced their intention to lay a third cable, avoiding the neighbourhood where volcanic action had been experienced. The company now announces that this cable between Java and Western Australia is completed, and that the line will be shortly opened for traffic. This will give the Australasian Colonies the advantage of a third cable to Java, and an alternative land system *vid* Perth to the overland line between Port Darwin and Adelaide, thus greatly adding to the security of telegraphic communication with Australasia.

Alternative Cable Communication to South Africa.—The ss. "Scotia," belonging to the Telegraph Construction and Maintenance Company, leaves the Thames on 3rd inst. for Cape Town, where she is expected to arrive on March 26, with the 1,530 miles of cable to be laid from Mossamedes to Cape Town. On the 4th inst. the India Rubber and Gutta Percha Company's ss. "Silvertown" will sail with cable to connect St. Paul Loando with Mossamedes and Princes Island with Bonny. When the former section and the cables to be laid by the Telegraph Construction Company mentioned above are completed, there will be continuous cable communication from Cape Town to England, in addition to that already existing from Durban to this country. As an instance of the rapidity with which events move in these days it may be mentioned that when this line is completed almost every port of importance on the East or West Coasts of Africa will have been connected by submarine cables within a period of nine years.

Morecambe.—A special meeting of the Morecambe Local Board was held on Tuesday evening last week. Messrs. Andrews and Preece, electricians, Bradford, together with their solicitor, attended before the Board in order to furnish any necessary particulars with reference to their proposed Provisional Order. They stated that in the event of the Board not opposing their application they were willing to fit up a central station and to supply the electric light for ordinary domestic purposes at a charge of 7d. per Board of Trade unit. For public lighting they were prepared to supply twelve 2,000 candle-power arc lamps, 100 yards apart, and at an elevation of 35ft. from the ground, for £25 per lamp per annum; or for 100 nights during the season at £10 per lamp, being 10s. each lamp per night. Six lamps for the same period would cost £11 each. In winter they could substitute incandescent lamps for street lighting at the same price as for domestic purposes, the expense of a 32-candle lamp of that description being estimated at from 28s. to 30s. per year. The Board thanked the firm for the information they had furnished, and promised to carefully consider the question.

Stanford's Map of the London Electric Lighting Areas.—Mr. E. Stanford has issued a new "Map of Metropolitan Railways, Tramways, and Miscellaneous Improvements, as deposited at the Private Bill Office, Nov. 30, for the Session 1889." In this map the "electric lighting areas" are very distinctly shown by means of different colours, and the companies applying for orders are indicated in each case by boldly printed figures, whose meaning is supplied by an index. This map will be indispensable to all who have to follow closely the progress of electric lighting in the metropolitan area. It must, however, be observed that the information which it affords relates only to the Bills now before Parliament, so that, for instance, the existence of the Chelsea Electricity Supply Company, whose Order was confirmed last year, and which promotes no Bill in the present Session, is not in any way alluded to. It is also noticeable that there is still a very extensive district in the south, and another south-west, which have not yet attracted the attention of any supply company. Even the Crystal Palace is left out in the cold. The principal defect of the map seems to be the absence of any indication of the particular local authority which has jurisdiction over the several areas.

Paris Exhibition.—The contract for the lighting of the American part of the Paris Exhibition has been awarded to the Heisler Electric Light Company, of St. Louis. The whole plant for this contract will be completed and tested before shipping at the St. Louis Illuminating Company's station, and the technical societies of the city will be invited to witness the test. The plant consists of a dynamo of 1,000 incandescent light capacity, showing the utility of an independent circuit system, each room or locality wired from both circuits. Lamps will be exhibited from 10 up to 300 candle-power. The automatic regulation will be so arranged as to indicate the reduction of power when the lights are turned off. Ten miles of circuit wire will be inserted, so as to indicate the practicability of carrying the current to any desired distance. Registering current meters will be included in the exhibit; twenty-four clusters of incandescents of various candle-power will be suspended from the ceiling, posts being provided with side brackets, such as are used for indoor, but in addition fifty street-lamp brackets will be fastened to posts, to indicate the system of street lighting used in a great number of American cities.

Testing Chain Cables by Electric Light.—An interesting experiment with the electric light has been successfully carried out recently by the River Wear Commissioners. Hitherto the testing and examining of chain cables had always been done in daylight, no artificial light being considered sufficient to detect the fractures in the cables after testing. That being the case, the management of the River Wear Commission directed that an artificial light of some kind should be experimented upon,

Digitized by Google

with the result that the electric light, applied by means of portable lamps attached to the caps of the examiners, has been adopted, and enables the Commissioners to almost double their output in connection with their testing department. Seven 300 candle-power "Sunbeam" lamps, run off one of Parson's turbo-electric generators, were originally installed; but the result of the fixed lights was not altogether satisfactory. Under these circumstances the localising of the light was considered the next best thing to do, and in order to accomplish this a 16 candle-power lamp was attached to the caps of the workmen known as the examiners, with a flexible cable connected with the main cable above, which allows the men to work within a certain radius. This device, which has proved a great success, was introduced by Mr. Hartness, the manager of the Test Works.

Norwich.—At a meeting of the Norwich Town Council on Tuesday last, a report was received from the Electric Lighting Committee to the effect that they did not consider themselves warranted in recommending that the Corporation should undertake the lighting of the city by electricity, but they should forward any scheme for the purpose. Mr. Squirrell said he was the father of the report, and added that there were two courses to be laid down—one was that the Council should take up the electric lighting of the city, and the other was that they should support any sound company that would do the work. As a matter of fact, it would be the best economy for the city to undertake it, the cost being about £15,000 or £20,000, but in the face of the large expenditure for sewerage, &c., that was about to fall upon the rates, he could not recommend the adoption of this course. There was a large demand for the new light, and he had in his hand a list of 60 persons who had applied for the light to be introduced into their shops. This was a fact that ought not to be lost sight of. Mr. Marshall had suggested that when the new sewerage were constructed troughs should be placed for the accommodation of those who required wires, and the Council ought not to obstruct the development of this new industry. It was resolved to consider the question at the next meeting of the Council.

Wakefield.—At the last meeting of the Wakefield City Council Alderman Peacock moved, "That a committee be appointed to consider the question of adopting the electric light for lighting the city, instead of the renewal of the gas contract." He said the contract with the gas company would shortly expire, and he found that the Corporation paid more than £1,908 per annum to the gas company for the public lighting of the city, including the public buildings; and he had an estimate, showing that the lighting by electricity could be done for £995. The estimate had been furnished by an eminent electrical engineer. Alderman Reynolds said he had some five years' experience in electric lighting in establishments of his own firm, and he thought there could not be two opinions with regard to the desirability of having the light where it could be obtained. It would be wrong, however, on his part to allow Alderman Peacock's statement to go forth without some qualification of it. The Mayor said he approved of this question having been brought before the Council for consideration; and he had no doubt that the matter would not be lost sight of by the Sanitary Committee. One thing, however, was certain, that it could not be disposed of prior to the time when the contract with the Gas Company would have to be renewed. Permission to withdraw the motion was then granted.

The Southwark and Deptford Tramways Company.—At the half-yearly meeting of the shareholders of this company on Monday last, the chairman, referring to a Bill now before Parliament, authorising the company to construct new tramways and for other purposes, said:—"With regard to mechanical traction, local authorities were a little sceptical as to mechanical haulage, and therefore the directors had not thought it advisable to jeopardise the safety of the whole Bill by insertion of any clauses in reference to which there could be an objection. They, however, asked for powers to acquire from the Board of Trade a License authorising the use of mechanical power, other than steam, for a period not exceeding twelve months, as an experiment. He was bound to state that he looked most hopefully to the development of electric power. He was not one of those who regarded steam as the be all and the end of all traction. He repeated he had the greatest possible hope in the future of electricity. In regard to its adoption he thought a traction company sufficiently strong financially should say to the tramway company, 'We are prepared to undertake to work your tramway at so much per mile, to include all cost of depreciation and repairs.' If this were done two things were certain; the success of the tramways—an object which he had very much at heart—and the success of the traction company. He firmly believed that electricity was designed to develop and increase the traffic upon the tramways to an extent which it was impossible should be done by any other means."

Barnet.—At a meeting of the Barnet Local Board last week the report of Mr. Preece and his assistant (Mr. Probert) was considered. Mr. Preece reported that the lamps were not all of the candle-power specified, and that although the machinery now employed was capable of supplying 71 lamps with 32 candle-power light, yet it was a great risk to continue the lighting with the existing apparatus. The whole of the apparatus should, in fact, be duplicated. Allowing 20 per cent. for absorption by the thick glass globe enclosing the electric lamp, the average candle-power of the so-called 32 candle-power lamps is, according to the photometric measurements of Mr. Probert, only 27·6, the light varying from 17·34 to 43·65 candles. After a long discussion Mr. Walker moved "That the contractor be called upon to provide uniform lights of 32 candle-power." This resolution, with the words "within fourteen days" inserted, was subsequently carried by five votes to four.—Messrs. Henry F. Joel and Co., electrical engineers, write us as follows:—"In pioneering the system of incandescent lamps in series for street lighting at High Barnet we have had to contend with great opposition and unusual difficulties; but even taking into account the stoppage of the light, owing to uncontrollable causes, such as wilful damage to our wires, &c., the whole of the failures during the past six months and severe winter weather have barely exceeded one per cent. of the total hours of lighting; and this, we submit, is very encouraging, and is, we believe, the best record of town lighting. In the opinion of many qualified engineers who have visited Barnet, the system of street lighting by 32 candle-power incandescent lamps is a success."

City Tradesmen and the Electric Subway Railway.—The members of the City of London Tradesmen's Club are among those who look with disfavour upon the proposed construction of the Central London Subway Railway. At a meeting of the club last week Mr. J. W. Thomas supported the scheme in a comprehensive Paper, which was met, except with the doubtful utterances of a single member, by a unanimous expression of disapproval. Let anyone consider, said Mr. Thomas, the necessities of London in the matter of travelling conveniences. While the population had increased 45 per cent., the traffic had increased no less than 760 per cent. in the United Kingdom, and it was a well-known fact that between 1878 and 1888 the increase of traffic amounted to 360 per cent. Everyone knew that trade begat trade, and that the facilities for travelling created travellers, and the point they should consider was that of the public convenience. Another advantage of the scheme was that the outlay of £100,000 upon the railway meant an increase in the ratable value of the district, and consequently it would be of general benefit to the ward. The railway would be completed within twelve months of its commencement, the thoroughfares would not be obstructed, and the work being carried out in sections only one portion of the street would be disturbed at a time.—Mr. T. Simpson opposed the scheme. He said a great number of houses along the line of route of railway from London Bridge to Stockwell were now "propped up." The proposed new railway would result in a similar propping up.—Mr. N. Phillips considered that it was one of the maddest schemes ever proposed in the City of London.—Mr. B. Turner stated that the electrically-propelled cars might stop short in the tubes, as was sometimes the habit of electrically-propelled cars above ground, and in that case the passengers would have to be dug up.

NOTES ON ELECTRO-MAGNETIC INDUCTION.

BY DR. J. A. FLEMING, M.A.

(Continued from page 393.)

Maxwell's Theory of Molecular Vortices.—The study of the phenomena of electro-magnetic induction naturally gives rise to the question, by what mechanism can this be brought about? Given a medium possessing certain mechanical qualities, such as elasticity, a definite density, and capability of relative displacement of its parts, is it possible to imagine a construction which will mechanically account for the effects we have produced in electrical phenomena? Maxwell has replied to this inquiry by presenting his theory of *Molecular Vortices* which was put forward in the *Philosophical Magazine* for 1861 and 1862. A general account of these conceptions of Maxwell has been given in the "Life of James Clerk Maxwell," and as the limits of such an elementary treatise as the present one preclude any detailed account of the mathematical portion of this theory, we shall borrow the language of the authors of the above-mentioned work* in describing it. Maxwell supposes that any medium which can serve as the vehicle of magnetic force consists of a vast number of very small bodies called *cells*, capable of rotation, which we may consider to be spherical, or nearly so, when in their normal position. When magnetic force is transmitted by the medium or acts through it these *cells* are supposed to be set in rotation with a velocity proportional to the intensity of the magnetic force, and the direction of rotation is related to the direction of the force in the same manner as the *twist* and *thrust* of a right-handed screw. We have thus all the magnetic field filled with *molecular vortices*, as Maxwell calls them, all rotating round the lines of force as axes. These cells as they revolve tend to flatten out like revolving spheres of fluid, and to become oblate spheroids; they thus contract along the lines of force and expand at right angles, creating a *tension* along the lines of force, and a *pressure* at right angles to them. These cells are supposed to be elastic spheres closely packed together and incapable of separating from each other. If any line of cells is set rotating the contraction of each cell along its axis of revolution must set up a tension or pull along that line, it behaves like a filament of muscular tissue, and contracts in length and swells out or increases in thickness. If several adjacent lines of cells or vortices are all set revolving in the same direction, the swelling out of each line causes them to press on each other; hence there is a lateral pressure and a longitudinal tension. In any space filled with these cells so revolving the lines of tension or axes of revolution of the cells will take up certain positions, depending on the necessity for the stresses to adjust themselves to equilibrium, and Maxwell has shown mathematically that such a system of lines of tension and correlated pressure is a force system which will distribute itself in a manner similar to that in which we find actual lines of magnetic force to do, and that the behaviour of magnetic poles to each other can be explained fully on the assumption of a tendency of lines of force to contract like elastic threads along their length, and to push one another apart when laid parallel and proceeding in the same direction. To account for the transmission of rotation from one cell to another in *the same direction*, and from one line of cells or vortex to the next, Maxwell supposed that there exists between the cells a number of extremely minute spherical bodies which can roll without sliding in contact with the vortex cells. These bodies serve the same purpose as "idle wheels" in machinery which, coming between a driving wheel and a following wheel serve to cause both to turn in the same direction. These minute spheres Maxwell supposed to constitute *electricity*. We shall speak of them collectively as the electric matter. These electric particles are furthermore supposed to be free to move in conductors; but in dielectrics they are tethered to one spot, or rather into one molecule of the substance, and can only be displaced a little way against an elastic resilience, which brings them back to their original position when the displacing force is withdrawn. Furthermore, we must assume that both cells and particles are very small, compared with the molecules of matter. The passage of electric particles from molecule to molecule in conductors, however, sets up molecular vibration, or generates heat. Something of the nature of friction must, therefore, be also postulated to account for the fact that the electric particle, when set moving in a conductor, gives up energy to the molecules, and the energy is in them dissipated in the form of heat. That there is some kind of rotation going on along the lines of magnetic force has been held by Maxwell to be indicated by the behaviour of a ray of polarised light when passing through a dielectric along a line of magnetic force, and he states* that Faraday's discovery of the magnetic rotation of the plane of polarised light furnishes complete dynamical evidence that wherever magnetic force exists there is matter, small portions of which are rotating about axes parallel to the direction of that force. The further assumption is made that the *cells* are composed of an elastic material, and that they can be distorted or squeezed slightly, returning again in virtue of their resistence to their original form. In order to obtain a clear mechanical conception of the inter-relation of the idle wheels or the electric particles and the revolving cells or lines of induction, let us figure to ourselves one element of the mechanism as it is supposed to exist in the dielectric.

Consider A and B (*see* Fig. 26) to be two wheels of india-rubber, and that C is another small wheel lying between A and B and transmitting motion from one to the other. Let C be

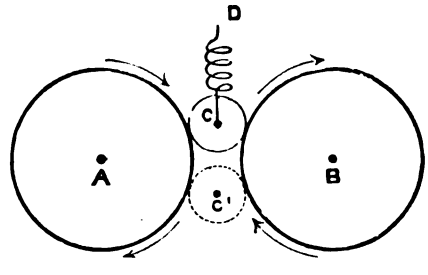

FIG. 26.

tethered to a fixed point, D, by an elastic spring, and let C be at the same time capable of rotation round its centre. Suppose A is set in rotation, clock-hand wise, whilst B is held fast, and that the wheel C cannot slip on A, the result will be to drag down C to the position of C^1, stretching the spring and displacing C. Let B be then set free; the wheel C continues to roll on A, and transmits its rotation to B. Owing to the assumed elasticity of the discs A and B, the wheel C can be drawn down between them, and yet within the limits of its displacement equally transmit the rotation of A to B without slip. This same action of a preliminary displacement of C and subsequent rotation of B will take place if the wheel B possesses *inertia*—that is, if we assume it to be a heavy wheel which cannot in virtue of its mass be set rolling with finite speed in an infinitely short time.

If, then, we suppose a long row of such wheels with intermediate displaceable idle wheels, the main wheels being heavy bodies, the result of causing the first wheel to rotate would be to propagate along the line a successive displacement of the idle wheels, and to set the main wheels successively in rotation. Translating these mechanical concepts into their electrical equivalents Maxwell considers that the heavy wheels are the analogues of the molecular votices or lines of force, and that their density is determined by what we call the magnetic permeability of the medium; the elastically displaceable idle wheels are the electricity in the dielectric; and that when a line of force is brought into existence in a dielectric, or, in other words, when a line of cells is set rotating, this action propagates itself outwards, producing successive displacements of the electric particles, or generates a displacement wave, and is

* "Life of James Clerk Maxwell." By Lewis Campbell and William Garnett. 1st Edition. 1882.

The general description of Maxwell's views in the above-mentioned work is due to Prof. Garnett, and in the annexed paragraphs the expository account of this theory is taken in part almost verbatim from the pages of this book.

* Article "Faraday," *Encyclopædia Britannica*, 9th edition.

Digitized by Google

accompanied by the successive appearance of rotation in the cells, or by the propagation of a wave of electromagnetic force.

The velocity of propagation of this wave will depend on the elastic forces restraining displacement, and on the inertia of the revolving vortices. We have seen that the elasticity of the dielectric is expressed by the quantity $\frac{4\pi}{K}$, where K is the specific inductive capacity. We shall see later on that the electromagnetic density of the medium is expressed by $4\pi\mu$, where μ is the magnetic permeability.

The velocity of propagation of a disturbance through an elastic medium is numerically equal to the quotient of the square root of its effective elasticity e, by the square root of its density d, or by $v = \frac{\sqrt{e}}{d}$.

If, then, for the electromagnetic medium $e = \frac{4\pi}{K}$ and $d = 4\pi\mu$ we have $v = \frac{1}{\sqrt{K\mu}}$, or the velocity of lateral propagation of a wave of electric displacement or of magnetic force in a medium is numerically equal to the square root of the reciprocal of the product of its specific inductive capacity and its magnetic permeability. Such a mechanical hypothesis shows us how the spin of one line of vortices results in producing displacement of the idle wheels or electricity along lines which are circles described round the initial vortex as axis, and in propagating outwards the vortex spin or magnetic force with a finite velocity from one line of molecular vortices to another.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

SECTION III.—MAGNETIC FIELDS OF COILS AND SOLENOIDS.

(Continued from page 435.)

[In the curve showing the strength of field at various distances from a coil along its axis (Fig. 135) more points on the curve should have been taken. It then appears that when the distance from the coil is very small the rate of decrease of field is more gradual and the curve is of the shape shown in Fig. 135A. For some little distance each side of the coil the fall

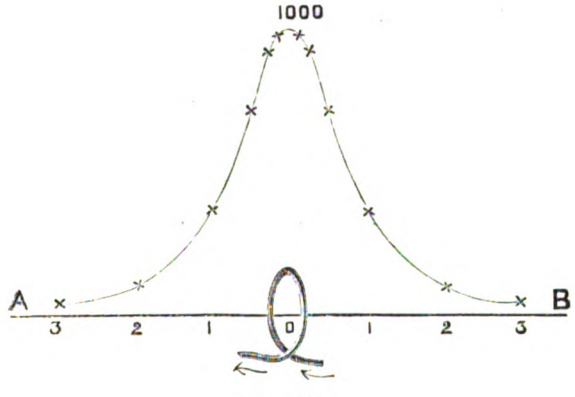

FIG. 135A.

in strength of field is very gradual; then it suddenly becomes rapid, and then gradual again. Its most rapid fall is at a distance equal to half the radius of the coil. Also in the numerical example given at the end, the field at the coil centre should be

$$\frac{113}{4} = 28{\cdot}25 \text{ C.-G.-S. units.}]$$

146. *Magnetic Fields due to a Coil and Magnet Superposed.*—We have already discussed the case of two uniform magnetic fields superposed at right angles to each other (para. 119). Referring again to the figure (Fig. 80), it was shown that the ratio between the two superposed fields f and H was the tangent of the angle which H, the total controlling field, makes with the resultant. Let us now take the practical case which occurs in every tangent galvanometer, viz., the superposition at right angles to each other of the controlling field due to the earth or a permanent magnet, and the field due to the current in the coil. A little experiment carried out with a Thomson potential galvanometer coil and a battery of secondary cells may serve to make this action clear. This instrument is of the same external appearance as the current galvanometer described in para. 132, but instead of a few turns of stout copper strip the coil is wound with some 8,000 turns of German silver wire, amounting to a resistance of 9,830 ohms. The needle-box, movable along the wooden platform, being removed, the magnetic fields produced in the region of the coil were examined by iron filings sprinkled on a sheet of stiff card placed on the platform. First, without any current through the coil, the controlling magnet N S was placed over it in the usual position as used with the instrument (Fig. 136). The iron filings then revealed the kind of field produced in the region of the coil. The lines of force here pass straight from one pole of the magnet to the other, producing at the centre of the coil a field parallel to its plane. When in use the coil and magnet are put in the

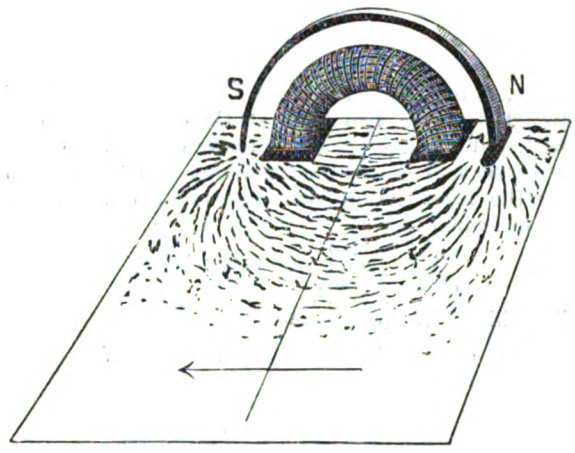

FIG. 136.

plane of the magnetic meridian so that the earth's horizontal field is added to that of the magnet. This field alone is far too weak to be exhibited by iron filings. The central line in the figure represents the axis of the coil, and is the line along which readings are taken with the instrument. Along this axis we may consider the controlling field produced by the magnet and the earth to be everywhere in the direction of the arrow—viz.: at right angles to the axis. For even at positions along the axis remote from the coil where the lines are in curves, the direction of each line of force *as it crosses the axis* is a tangent to the curve, and, therefore, at right angles to the axis. Secondly, the controlling magnet was removed, and the ends of the coil connected by leading wires to the terminals of 21 cells, giving a difference of potential of 42 volts at the terminals of the coil. A vigorous effect was then produced on the filings, which arranged themselves into the form in Fig. 137. It will be noticed that as regards the axis of the coil, this field is at right angles to that set up by the controlling magnet. The current was sent round the coil in such a direction as to cause the direction of the lines to be *towards* the coil, as shown by the arrow. Lastly, the controlling magnet was placed over the coil, as at first, the current being kept on the while, resulting in the change in direction of the filings represented in Fig. 138.

Here we have an actual representation of the resultant field, that is, the character of the field resulting from the combined effect of two distinct fields at right angles to one another. The arrow in this figure indicates the direction of the lines of the resultant field at the centre of the coil. As we take points on the axis further away from the coil the effect of the

Digitized by Google

latter becomes rapidly decreased, and the controlling field predominates, so that the lines become nearer and nearer at right angles to the axis. The direction of this resultant field is precisely that taken up by a magnetic needle free to move when placed at a given position on the axis of the coil. If the needle is at the centre of the coil we have an ordinary tangent galvanometer, and if the box containing the needle can be shifted along the axis of the coil, as in Sir William Thomson's graded galvanometers, we have instruments which still follow the tangent law, and which have, in addition, the advantage of great variation in

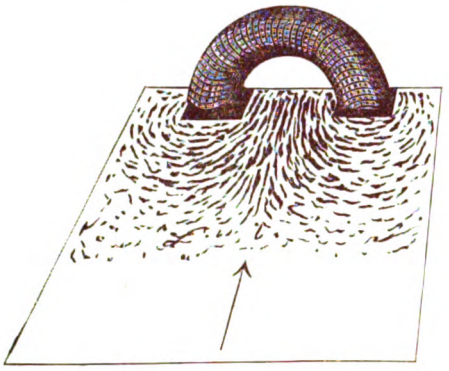

Fig. 137

sensibility, as before explained. Let us form a practical idea of the strengths of the two fields at the centre of the coil, their resultant, and its direction in the above case. The outside diameter of the coil was 14 centimetres, and the inside 6 centi metres; the mean radius was therefore 5 centimetres. The current was equal to

$$\frac{\text{volts}}{\text{ohms}} = \frac{42}{9830} = \cdot00427 \text{ amperes.}$$

Dividing this by 10 we have the

current in C.-G.-S. units = ·000427.

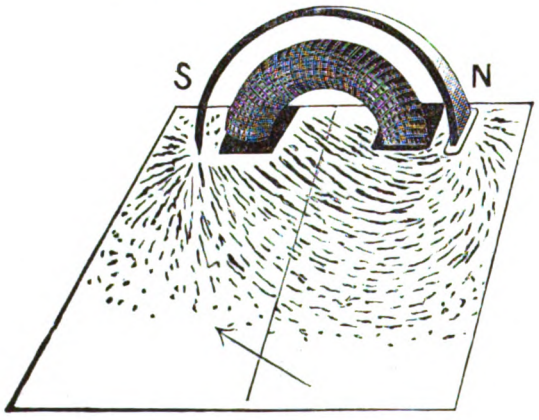

Fig. 138.

The number of turns of wire being 8,000, the field at the centre of the coil due to the current was :—

$$\frac{2\pi \times \cdot000427 \times 8000}{5} = 4\cdot3 \text{ C.-G.-S units.}$$

Now, the controlling field at right angles to the above consisted of the field of the magnet, which was 10·56 C.-G.-S. units, plus the earth's horizontal field ·18 unit, total 10·74 units. The ratio of the coil field to the controlling field is the tangent of the angle which the resultant makes with the controlling field, that is

$$\frac{4\cdot3}{10\cdot74} = \cdot4003 = \text{tangent of } 22^\circ \text{ nearly.}$$

A small magnetic needle freely suspended at the centre of the coil would therefore turn through this angle when the above potential difference was applied at the terminals of the coil.

(To be continued.)

THE TESLA MOTOR.

Although the theory of the Tesla motor is now so widely known—though doubtless better known than understood—yet the practical construction of the apparatus has not yet been explained. The following brief description will therefore be read with interest :—The field-magnet consists of a laminated ring, with internal projections like Paccinotti teeth. It is wound with two independent circuits, A and B ; in the motor from which the diagram is taken there are 12 scctions in all, and the two coils are wound upon every three sections alternately. The three sections on the right of the figure, and the three on the left, the two being joined in series form circuit A. Similarly, the three upper and the three lower sections form circuit B. The resultant fields of each coil independently are shown by the lines $N_A S_A$, $N_B S_B$, respectively. But the currents in these two circuits are relatively displaced by $\frac{1}{4}$ phase. Thus, when the current in A is at a maximum, the current in B is at zero, and the resultant field for both coils passes through $N_A S_A$; so, also, when B is at a maximum and A is at zero, the resultant is $N_B S_B$. But when the two currents are equal the resultant passes through the line N S ; the direction of the resultant is, of course, reversed at the moment when the two currents are equal in value but opposite in direction.

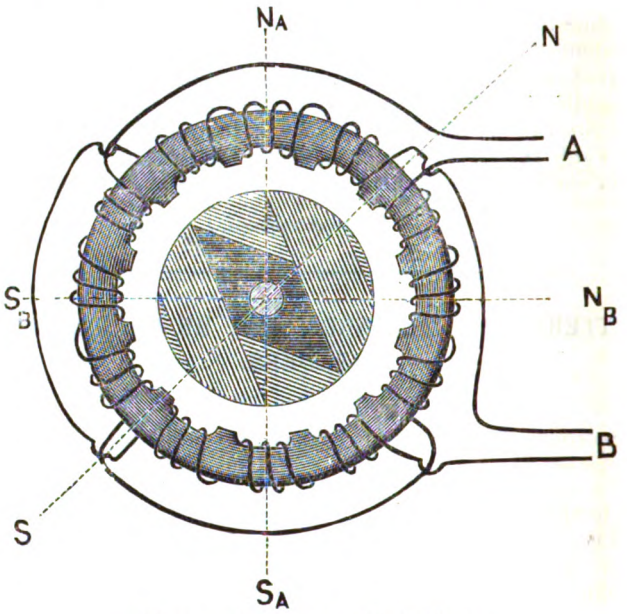

Diagram of Windings of Tesla Motor.

The armature is drum-wound, with four coils, as shown, each being short-circuited on itself. The resultant axis passes through N S.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"On Certain Phenomena Connected with Imperfect Earth in Telegraph Circuits."

BY A. E. KENNELLY.

(Concluded from page 456.)

One of the most interesting features in the geology of Nova Scotia is that the Atlantic seaboard presents an uninterrupted line of Lower Cambrian formation. The relation of this fact to our immediate subject is patent when we remember that these rocks—early in order of geological structure, and said to be almost destitute of organic remains—are here almost entirely composed of argillites, quartzites and micaceous schists—slates and grits—substances experimentally known to be non-conductors ; and according to the published Papers of Prof. Honeyman, who has studied the geology of Nova Scotia for many years, no other formations mingle with the Lower Cambrian in the structure of the Halifax basin except the still lower archæan granites, all of which are presumably non-conductors. In fact, the renowned natural advantages of Halifax Harbour are due to the unrelieved presence of these abrupt slaty cliffs that immediately underlie the soil for miles inland.

The question then arises, Granting that on the above geological considerations the rocky basin of the harbour and foundation of the city form an insulating crust, or one, at least, interposing a decided amount of resistance between the superficial conducting system and the ocean or earth's mass—is the resistance that can be jointly

Digitized by Google

offered by the three cable sheathings and the whole waterway between the cable house and open sea of sufficient magnitude to produce the degree of interference observed ?

The answer, which seems to be affirmative, strictly demands a computation of the resistance offered by the entire mass of sea water in the harbour under those conditions. This would be a gigantic problem to solve with any pretence to accordance with nature ; but for the purposes of the case such limitations may be admitted as shall greatly simplify the calculation.

The map shows that three channels open upon the inner harbour, one running inland through the narrows, and two passing seawards —the eastern passage, and the main or southern entrance. The inland channel terminates in a bay some miles beyond, and may be considered to be practically insulated with the rest of the basin. The waterway in the shallow and narrow eastern passage will evidently offer a comparatively high resistance compared with that of the main entrance, which, therefore, demands principal attention.

The general mathematical theory of the earth's resistance is given in Schwendler's "Testing Instructions," following the reasoning of Smaasen's theory, published in 1847. It is shown that if a perfectly conducting small spherical electrode of radius r were situated concentrically within a larger hollow perfectly conducting sphere of radius R, and the intervening space filled with a homogeneous substance of specific resistance ρ, the resistance of any elementary spherical shell of radius x, measured from the common centre, would be $\frac{\rho\, dx}{4\pi x^2}$, and hence the total resistance (ω) between the two spherical electrodes would be the integral of this quantity between the limits $x = \mathrm{R}$ and $x = r$; whence

$$\omega = \frac{\rho}{4\pi}\left(\frac{1}{r} - \frac{1}{\mathrm{R}}\right).$$

If the radius R of the outer electrode be indefinitely increased, the resulting equation becomes

$$\omega = \frac{\rho}{4\pi r},$$

which represents the resistance of an unlimited medium of resistance ρ to a current passing from a sphere of radius r to its ultimate confines. Similarly, a second small spherical electrode of radius r_1 would offer under the same circumstances a resistance

$$\omega_1 = \frac{\rho}{4\pi r_1};$$

and if these two small spherical electrodes were placed so far apart in the medium that their direct influence on each other's lines of current-flow would be very small, the resistance between them would be

$$\omega + \omega_1 = \frac{\rho}{4\pi}\left(\frac{1}{r} + \frac{1}{r_1}\right)$$

—a result equivalent to the statement that almost all the lines of current-flow issuing from the surface of each electrode would unite with least opposition at indefinitely great distances, and after indefinite diffusion throughout the medium.

If the system were then symmetrically divided by an unlimited insulating plane, the resistance (Ω) between the hemispheres on one side of the plane would be double the above, or

$$\Omega = \rho\left(\frac{1}{c} + \frac{1}{c_1}\right),$$

where c and c_1 are the circumferences of the two hemispheres.

This would then be the resistance between two hemispherical electrodes embedded in the bounding plane surface of an indefinitely extending homogeneous medium ; and if the electrodes were not hemispheres, but vertical plates embedding active surfaces (s and s_1), the above formula would approximately apply, if c and c_1 be the circumferences of equivalent hemispheres exposing those areas respectively, and the transformed equation would be

$$\Omega = \frac{\rho}{\sqrt{2\pi}}\left(\frac{1}{\sqrt{s}} + \frac{1}{\sqrt{s_1}}\right)$$

—an equation independent of the distance between the plates.

Similar results are obtained and published by MM. Mascart and Joubert by separate reasoning. The formula applies to the earth's resistance in a telegraphic circuit, on the assumption that our planet has a practical uniform conductivity, and forms practically an indefinitely extended medium.

In the absence of experimental evidence it would be difficult to say how far the variable conductivity of the earth's mass would affect the application of this formula. The conductivity of the material composing the earth's crust probably varies considerably in different localities, and is generally not the same as that of the ocean, for example. It might even be assumed that the resistance of the primary rocks is so great as to limit the conducting area almost entirely to the superincumbent stratified formations.

In that case the earth's telegraphic resistance would be mort nearly comparable to the resistance between two small distince electrodes embedded in the surface of an indefinitely extended sheet of uniform thickness and conductivity. On this supposition, let d be the depth of the earth's conducting crust, assumed to be uniform, then the resistance, Ω (*vide* Appendix), between two earth-plates of active surfaces (s and s_1) would be, approximately,

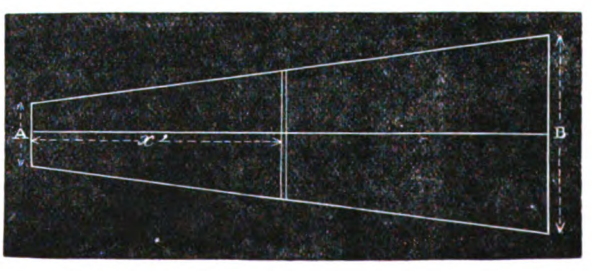
$$\Omega = \frac{\rho}{\sqrt{2\pi}}\left(\frac{1}{\sqrt{s}} + \frac{1}{\sqrt{s_1}}\right) + \frac{\rho}{\pi d}\log_{\varepsilon}\left(\frac{4\,\mathrm{D}}{d}\right).$$

This equation is the same as that of Schwendler last stated, but with the addition of a second term involving D, the distance between the plates ; so that on this theory the earth's resistance would increase with the length of the circuit. If submarine cables were sufficiently well insulated, it would be possible to ascertain which of these two theories is nearer to the truth, by measuring the conductor resistances of cables which are laid in duplicate or triplicate between two stations ; the difference between the resistance of any pair looped, and the sum of their separate resistances employing the earth circuit, giving, of course, double the earth's resistance between the terminals. It is, however, impossible to decide from present experimental evidence in this way, since not only does the difficulty of accurately measuring these quantities probably increase with the square of the length of cable, owing to leakage and other causes, but also because this second term of the last equation whose existence is in question must in all cases be very small.

Generally speaking, therefore, the experimental evidence may be said to establish the results given by Schwendler's formula, namely, that when the earth-plates are separated by any distance great compared with their dimensions, the resistance varies with their active area, and is independent of their distance.

Schwendler gives an estimated superior limit of the specific resistance of the earth in India as 3,300 ω, or about 100 times that of saturated zinc-sulphate solution at 10°C.

Returning to the resistance offered by the waterway in the main entrance of Halifax Harbour, we may suppose a current to be flowing seawards through it and the cable sheathings from the cable house. The lines of flow will permeate its whole area, and the equipotential surfaces may be supposed to form across it in successive curves. These surfaces will be practically vertical, and a position has to be assumed for the ultimate one representing the zero-potential, or the surface that may be considered to mark the limit of perfect earth connection. Theoretically, of course, this limit would be far out in the ocean, but it may be arbitrarily assumed that a vertical plane shown on the map by a dotted line connecting the Thrumcap with the Mars Rock buoy represents this boundary, and that the resistance to earth of the ocean mass outside this plane is altogether negligible. The two other dotted lines converging from this base up to the cable house—one skirting Sandwich Point, and the other running over Maugher Beach—are intended to represent what may be considered the simple boundaries of an equivalent waterway equal in conductivity to the actual one. The average depth may be taken as 14 fathoms. We have, on this supposition, a mass of sea-water resembling a wedge with a blunt point, the breadth of the base being 1·2 knot ; the breadth at the apex, say, 5 metres ; the length, measured perpendicularly to the base, 4 knots ; and the depth 14 fathoms. Strictly speaking, the equipotential surfaces of flow



will be curves convex to the ocean, but the error introduced will not be great if we consider them as planes parallel to the base, or zero surface. Since the fall of potential will take place with equal rapidity through the water and through the sheathings, the resistance of the latter may be taken into account later and independently. The resistance of any elementary lamina of thickness dx, distant x from the cable house, will be $\frac{\rho\, dx}{h(ax+b)}$, where ρ is the specific resistance of the water, h the depth, while a and b are constants ; so that the total resistance between the two ends is

$$\mathrm{R} = \frac{\rho}{a\,h}\log_{\varepsilon}\frac{\mathrm{B}}{\mathrm{A}},$$

where B and A are the breadths at the base and apex.

Digitized by Google

In this case $a = \frac{1{\cdot}2}{4{\cdot}0} = 0{\cdot}3$;

$h = 14 \times 6 \times 30{\cdot}5 = 2{,}560$;

$\frac{B}{A} = \frac{185{,}000 \times 4{\cdot}2}{500} = 1{,}550$;

$\rho = 31$.

The specific resistance of a saline solution of density 1·027 has been observed experimentally to be about 31 ω at 5° C.

With these data,

$$R = \frac{31 \times 2{\cdot}72 \times 3{\cdot}19}{0{\cdot}3 \times 2{,}560}$$

$$= 0{\cdot}35\ \omega,$$

about one-third of an ohm, equivalent to a conductivity of ..... 2·9 mhos.

Compared with this, the conductivity of the eastern passage channel may be estimated at about one-fourth, or ..... 0·7 mho.

The conductivity of the two cable sheathings, each consisting of ten No. 6 wires, and length 4·2 knots, would be $20 \times 0{\cdot}020$ ..... = 0·4 mho.

And, finally, the conductivity of seven knots of cable sheathing in the eastern passage, $10 \times 0{\cdot}012$ ..... = 0·1 mho.

Total conductivity ..... 4·1 mhos.

equivalent to a joint resistance of 0·24 ω. So that if the above reckoning is sufficiently fair the resistance between the cable-house and the ocean is about a quarter of an ohm.

The resistance actually offered can be estimated from the data of Experiment 11, as follows :—

The E.M.F. in the exciting circuit was about 15 volts ; the resistance, 66 ω in the cable and earths, and 24 in the battery—total, 90 ω. In the Rye Beach circuit the resistances at the time were, approximately—

Observing mirror	2,000 ω
Cable conductor	5,800
Relay at Rye Beach	1,000
Total	8,800 ω

Since the interference current observed in this circuit was, as already mentioned, 5×10^{-6} amperes, the E.M F. impressed upon the cable due to interference was

$$5 \times 10^{-6} \times 8{\cdot}8 \times 10^{3} = 0{\cdot}044 \text{ volt};$$

and, consequently, if x be the required resistance of the general earth connection,

$$x : 90 :: 0{\cdot}044 : 15,$$

or

$$x = 0{\cdot}26\ \omega,$$

or an actual resistance of a quarter of an ohm. The agreement between the actual and measured values is really much closer than the accuracy of either determination would warrant.

The only experimental results still left unaccounted for are those of Nos. 3, 4, 5, and 6, in all of which the six-mile earth was used either in the exciting or observing circuit, and since Experiment 13 proved that this earth-plate was outside the limits of the semi-insulated basin, as might be expected from its position on the map, it would be impossible to account for the interference in those cases on the score of a common imperfect earth. Reflection shows, however, that the interference observed would be an indirect necessary consequence of the imperfect earth, since the six-mile earth, when connected to either main circuit, forms a cable-loop of, say, 10 knots within the limits of the semi-insulated basin, and a slight variation in the potential of the basin is calculated to produce a considerable electrostatic effect on the cable. It has, in fact, been found experimentally that when 1,000ft. of insulated cable core (of similar capacity to that of the cables at Halifax) are coiled in an insulated tank and left in communication with the earth through a mirror instrument, the electrostatic disturbance of the mirror is about equal to that observed in these experiments (3-6) when the potential of the tank is altered by 0·2 volt. The total charge passing through the mirror in Experiments 3 and 6 would be the resultant effect of the whole system of harbour potential variation on the four knots of cable under observation, except in so far as the capacity of the cable seawards would modify the influence. In Experiments 4 and 5 the interference would, on the other hand, be due to electrostatic charge entering the observing circuit owing to the variation in the harbour potential, electrostatically produced by the loop of exciting cable traversing it. An external average variation of 0·01 volt in the potential of the basin would suffice to account for the degree of interference observed ; and this amount of variation, it is evident, the conditions amply supply. Experiment 13, contrasted with Nos. 9 and 11, showed that the interference observed in cases 3, 4, 5 and 6 was of an electrostatic nature.

The sensitiveness of a cable to external electrostatic influence can be shown experimentally by joining up a mirror galvanometer in circuit with 100 miles of cable and earth. If the distant end be sealed, and laid for two or three feet in an insulated joint trough filled with water, the potential of which is capable of being varied suddenly through 100 volts (from + 50 to − 50), the effect is immediately visible on the galvanometer ; and in fact, simple signals have been transmitted in this way from ship to shore through the coatings of a joint.

The hypothesis of an insulated or semi-insulated basin, therefore, satisfactorily explains all the phenomena observed. It accounts, first, for the meteorological disturbances which are observed on the cables, since any alteration of the charge or position of electrified clouds in the vicinity of the harbour may affect the distribution of charge in the cable to an extent that would not be possible if the harbour were in more perfect electrical communication with the ocean or earth's mass ; and all the phenomena experimentally observed can be traced either to the direct or indirect effects of this imperfect earth connection—directly by conduction, indirectly by induction.

Assuming, then, that the Lower Cambrian rocks effectively insulate the Halifax basin, it is necessary to suppose that the same effect would be produced at any landing place on the Atlantic shore of Nova Scotia, where these rocks so generally prevail. This is also corroborated by the fact that previously at Torbay some difficulty of the same kind appeared when attempts were originally made to utilise an ordinary earth connection for an overhead Morse circuit. The interference with the cables thus set up rendered a special earth necessary for the land line in the bay. The fact that no interference was visible between the cables themselves is accounted for by the open landing place and absence of any such basin as Halifax Harbour presents.

In Mr. James Graves's Paper on earth vibrations, already alluded to, mention is made of the slaty character of the rock in the neighbourhood of the station, and so favours the supposition that the interference there observed was due to the same causes.

It is said that in the Lake Superior region of the United States great difficulty has occasionally been found in obtaining efficient earth, even when no local cause for the deficiency has been apparent. I am indebted to Prof. Moses G. Farmer for the facts of a case which came under his own notice, where an earth connection, apparently good and well situated, was found useless, and measurement showed that its resistance to earth was 12,000 ω. I also owe to him the information that interference due to imperfect earth was found in 1869 at St. Pierre Miquelon, the Morse signals on the St. Pierre Placentia circuit affecting the Atlantic cable to Brest, and that special measures had to be taken to effect a better earth connection.

Generalising from these facts, it would seem that there may be difficulty in obtaining good earth at cable stations opened on a shore of primary or metamorphic rock, and that permanent interference beyond remedy by earth connection is possible between cables landed in a basin of such formation ; so that if this statement receive confirmation at the hands of the members of this institution, it will be evident that a due regard will be given to geological conditions by electrical engineers among the many incidental considerations that determine their selection of a cable's landing place.

APPENDIX.

On the resistance between two electrodes of active surface (s and s_1) embedded in the surface of an indefinitely extended homogeneous medium of specific resistance ρ comprised between two unlimited parallel planes separated by a perpendicular distance, d, the distance between the electrodes being represented by D.

Let r and r_1 be the radii of the equivalent hemispheres exposing surfaces of s and s_1 respectively. Then, if an infinitely thin perfectly conducting hemispherical shell of radius d concentrically surrounds each of these electrodes, these shells will touch the opposite bounding plane of the medium, and the resistance between them and their included electrodes will be

$$\frac{\rho}{2\pi}\left(\frac{1}{r} - \frac{1}{d}\right) \text{ and } \frac{\rho}{2\pi}\left(\frac{1}{r_1} - \frac{1}{d}\right) \text{ respectively.}$$

If D be large compared with d, these two shells may be approximately considered as two paralled cylinders of radius $\frac{d}{2}$ traversing the medium at right angles to the bounding planes, and their surface potentials may be written*—

$$V_1 = \text{constant} - \frac{c\rho}{2\pi d} \log_\epsilon \left(\frac{\frac{d}{2}}{D}\right);$$

$$V_2 = \text{constant} - \frac{c\rho}{2\pi d} \log_\epsilon \left(\frac{D}{\frac{d}{2}}\right),$$

* See Mascart and Joubert's "Electricity and Magnetism," Vol. 1., p. 235.

Digitized by Google

where V_1 and V_2 are the potentials and c the strength of current.

$$\therefore V_1 - V_2 = \frac{c}{2\pi d}\left(\log\frac{2D}{d} - \frac{\log d}{2D}\right),$$

$$\therefore \text{Resistance} = \frac{\rho}{\pi d}\log_\epsilon\left(\frac{4D}{d}\right);$$

so that the total resistance,

$$\Omega = \frac{\rho}{2\pi}\left(\frac{1}{r} + \frac{1}{r_1} - \frac{2}{d}\right) + \frac{\rho}{\pi d}\log_\epsilon\left(\frac{4D}{d}\right);$$

and since d is large,

$$\Omega = \frac{\rho}{\sqrt{2}\pi}\left(\frac{1}{\sqrt{s}} + \frac{1}{\sqrt{s_1}}\right) + \frac{\rho}{\pi d}\log_\epsilon\left(\frac{4D}{d}\right),$$

approximately.

PATENT RIGHTS IN SECONDARY BATTERIES.

The *Electrical World* (New York) publishes the following interesting statement from President D. H. Bates, of the Electrical Accumulator Company :—"The manufacture of secondary batteries in the United States is increasing rapidly with the growing demand for this form of apparatus in electric lighting and applications of power. The question as to whether or not the broad features of improvement attributed and patented to Faure are to be secured to his assignees, the Electrical Accumulator Company, is now in the hands of Judge Cox, and a decision will be rendered very shortly. The recent decision in the United States Supreme Court in the Bate refrigerating case has eliminated the only defence having any apparent merit. Faure's invention, as is well understood, was the application of an active material to a plate or support prior to immersion in the battery fluid. Subsequent inventors modified the nature and form of the support plate and the manner of combining this support plate and the active material. Among batteries now obtainable, whether at the hands of authorised manufacturers or infringers, are those having a support plate of lead, others having a support plate of lead and antimony with perhaps a little mercury added ; and, as regards the form of plate, the key-lock principle is applied to all. Perforations having a smaller diameter at or near the centre of the plate meet with the greatest success ; others have cells or perforations, the greatest diameter being at points intermediate between the surfaces of the plate. Your patent record shows that the specific modifications mentioned were long since contemplated and patented by an English inventor.

"The result of the recent interference between the application of John S. Sellon, of Hatton-garden, England, and Edmond Julien, assignor to the Julien Electric Company, is shown by the issue to the Electrical Accumulator Company (Sellon's assignees) of patent No. 396,958, dated Jan. 29, 1889, claim 2 being the issue in interference, to wit : 'In a secondary battery a plate, element, or support containing lead and antimony in combination with an active material.' Recent publications emanating from Julien's assignees give an impression widely at variance from what the issue of this patent shows to be the facts. The language of the technical expert of the Patent Office, not referred to in the publication of the Julien Company, shows what the facts really are :—'If Sellon was the first to use plates formed of lead and antimony, or two or more metals, of which lead and antimony are essential, I can see no good reason why he should not claim his invention in such broad terms as would prevent its being pirated by the addition of a small percentage of some other metal. The addition of a small proportion of zinc, tin, or bismuth, all of which are well known constituents of type metals, which are essentially alloys of lead and antimony, would avoid any patent he might obtain unless he is protected by some such claim as the one in interference, and the purpose of the claim seems to be to protect him from just this danger. Julien's claim is included in and subordinated by the claim of Sellon, for the reason that it is directed to an alloy of which lead and antimony are essential ingredients.' The issue of this patent gives Sellon's assignees, the Electrical Accumulator Company, the control of the battery employing an alloy plate, whether the present suit based upon the Faure patent now in the judge's hands, and upon which a decision may be expected within a short time, is favourable or unfavourable.

"A second very important patent granted on the same date to the assignees of Sellon for improvements in secondary batteries, No. 396,770, is also of sufficient importance to merit special attention. This is intended to cover and covers a special form of perforated plate, such as is used by the Gibson Electric Company, and such as is shown in the recent modification of Faure's invention attributed to Anthony Reckenzaun. The Gibson battery makes more or less successful use of a perforated plate produced by piercing a sheet of lead with a series of perforations in such a manner that the openings at the surface of the plate are smaller than the diameter of the perforation at one or more points intermediate the surfaces. The claims of this patent, as will be seen from the example given, cover this construction ; for instance :—'In a secondary battery a plate, element or support having cells, perforations or receptacles, the diameter of which at or near one or both poles of the major axis is less than the diameter at one or more points intermediate said poles.' This gives the assignees of Sellon a practical control of the form of battery manufactured by the Gibson Company, the invention of Sellon, as shown by his English patent, having been perfected long before the construction was adopted by Gibson.

"The third patent covers the construction adopted by FitzGerald-Jones in England when they were manufacturing batteries for experimental or exhibition purposes. The FitzGerald-Jones plan was to mould a solid peroxide plate and attach a framework of celluloid to the edges and parts of the surface thereof. On the inside of this frame, between the frame and the peroxide plate, was a thin strip of platinum ; but this construction was contemplated and perfected by Sellon long prior to the time of its adoption by Fitz-Gerald-Jones. This third patent, No. 396,769, was issued on the same date as the others above referred to. One claim reads : 'In a battery a support or terminal containing a practically inoxidisable material, combined with a conductor of platinum and a mechanically applied active material substantially as described.'

"These three patents are all believed to be valid ; if so, their ownership places the Electrical Accumulator Company in position to control the accumulator or secondary battery industry of the Faure patent."

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, March 1st.

ROYAL INSTITUTION.

9 p.m. Evening Discourse, "Leigh Hunt." By EDMUND GOSSE, M.A.

SATURDAY, March 2nd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Experimental Optics (Polarisation : Wave Theory)." By the Right Hon. Lord RAYLEIGH, M.A., F.R.S.

MONDAY, March 4th.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Westminster Town Hall. "The Construction and Repair of Roads." By G. R. STRACHAN, A.M.I.C.E.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

TUESDAY, March 5th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture, "Before and After Darwin." By GEORGE JOHN ROMANES, M.A., F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed, "Alternate-Current Machinery." By GISBERT KAPP, A.M.I.C.E. At this meeting the monthly ballot for members will be taken.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture. "A Visit to the Moon ; how we got there and what we saw." By Prof. CARLTON LAMBERT.

WEDNESDAY, March 6th.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

7 p.m. Ordinary Meeting at the Westminster Palace Hotel, "Liquid Fuel." By E. A. BRAYLEY HODGETTS.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Arc Lamps and their Mechanism," By Prof. SILVANUS THOMPSON, D.Sc.

FINSBURY TECHNICAL COLLEGE ENGINEERING SOCIETY.

8 p.m. "Boiler Explosions." By L. PENDRED.

THURSDAY, March 7th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture, "The Venom of Serpents and Allied Poisons." By SIDNEY MARTIN, M.D., B.Sc.

FRIDAY, March 8th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "Notes on Mining in Spain, with special reference to the Lead Mines of Linares." By C. F. SMITH, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse, "The Discharge of a Leyden Jar." By Prof. OLIVER LODGE, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

THE SOCIETY OF ARTS' TRIALS OF MOTORS FOR ELECTRIC LIGHTING.

In our issue of February 15th we briefly announced that the trials of small motors for electric lighting, instituted by the Society of Arts, had resulted in the award of a gold medal to each of the four competitors. Without wasting time in recapitulating the history of this affair, which has, in fact, been already chronicled in these pages, we proceed briefly to describe the motors entered, and the result of the tests carried out by the judges. It will be remembered that at the request of the Council the duty of conducting the tests, and awarding the medals, was undertaken by Prof. A. C. W. Kennedy, F.R.S., Dr. John Hopkinson, F.R.S., and Mr. Beauchamp Tower. The four entries comprised one steam engine and three gas engines. The first was a compound semi-portable engine of eight nominal horse-power, by Messrs. Davey, Paxman and Co., of Colchester, the engine having cylinders 5·24 and 8·98 inches in diameter, and stroke of 14 inches, the mean boiler pressure being about 190lbs. per square inch. The gas engines were the "Otto," entered by Messrs. Crossley Bros.; Atkinson's "Cycle" engine, entered by the British Gas Engine and Engineering Company, London; and the "Griffin" gas engine, entered by Messrs. Dick, Kerr and Co., London. The "Otto-Crossley" engine was nominally of nine horse-power, with a cylinder of 9·5 inches diameter, 18 inches stroke, and making about 160

Digitized by Google

revolutions per minute. It was of the well known "Otto" type, but was fitted with a tube igniter instead of the slide valve usually employed in this engine, and, moreover, it had a counter shaft carrying a fly-wheel and running in bearings attached to the engine bed-plate itself. The object of this addition was to obtain a greater regularity of speed. As the "Otto" engine receives but one impulse in two revolutions, something of this kind is essential, but of course it takes power to work it. The Atkinson engine is of that remarkable design which, with one crank, gives four strokes of the piston for one revolution of the fly-wheel, and these strokes are of varying length. The stroke which takes the charge into the cylinder is 6·3 inches, the next stroke compresses that charge, and is 5 inches in length, the charge being thus compressed into a space of 1·3 inches. The compression being effected, ignition takes place, giving the working stroke, which is 11·13 inches in length. This stroke is followed by the exhaust stroke, which sweeps the products of combustion out of the cylinder, and is 12·4 inches in length. The cylinder is 9·5 inches in diameter. It will thus be seen that with this engine the two most important elements essential to economical working are obtained, namely, compression of the charge to whatever pressure may be desired, and a large range of expansion. In the engine tested the exploded charge was expanded to more than double the original volume before compression. In all other engines the greatest expansion of the heated gases is equal to the original volume swept through by the piston taking in the charge, and the contents of the cylinder are never expanded to less than from 30lbs. to 50lbs. per square inch at the moment of exhaust. The Atkinson engine made about 132 revolutions per minute, and it was of six nominal horse-power. The "Griffin" engine differs again from the preceding, in that while the "Otto" has a four-cycle series of operations—that is, four strokes for every working stroke, the engine being single-acting—the "Griffin" has a six-cycle arrangement, but as the engine is double-acting an impulse is given to the crank shaft at every third stroke, or for each revolution and a-half. The cycle at each end of the cylinder is (1) drawing in charge of gas and air; (2) compressing the charge; (3) igniting and expanding charge, *i.e.*, working stroke; (4) exhaust stroke; (5) drawing in charge of air; and (6) ejecting this as a scavenging charge. The engine was of eight nominal horse-power, making about 200 revolutions per minute, and it had a cylinder 9 inches in diameter, and 14 inches stroke.

Such, then, are the leading features of the four engines which remained for trial. Now, we may ask, as these awards were offered for engines specially suited for small electric lighting installations, what were the questions to be asked, what were the tests to be made, or, in brief, what are the requirements? It may be assumed that for this, as for most applications of power, the cost of the power may stand as the first question; the second must be uniformity in the number of revolutions per unit of time; the third must be freedom from the necessity for stoppages other than those required by the electrical demands; fourth, good design and workmanship, and therefrom durability; fifth, first cost; and sixth, cost of maintenance. The report of the judges gives us answers to most of these questions. It gives, also, a great deal of information which is, firstly, of interest to the technical educationist, and secondly, to the makers of engines, though the latter will probably continue to go to their own workshops for information. To put the main results before our readers without following the report into the thermo-dynamic considerations to which the examination of the figures and diagrams lead the judges, will occupy very little space. Taking the names of the makers in the alphabetical order, we have first the Atkinson "Cycle" engine. The gas used per indicated horse-power amounted to 18·8 cubic feet, and per brake horse-power 22·1 cubic feet per hour. The gas used for ignition was 4·5 cubic feet per hour, making the total consumption per indicated and per brake horse-power 19·2 and 22·6 cubic feet respectively. The cost of lubrication was equal to the cost of about 1·59 cubic feet of gas. The engine ran with great regularity, as will have been expected from the fact that not only did the crank get one impulse for every revolution, but the arrangement of the connecting gear between the piston and the crank is such than when the heavy pressure is at first generated by the explosion, only a small proportion of it comes directly upon the crank, the proportion becoming greater as the pressure falls with expansion. The mechanical efficiency of the engine reached 85 per cent., and 25·5 per cent. of the whole of the heat generated was converted into work. The judges speak highly of the economy of this engine, of its regularity of speed, and of the mechanical arrangement.

Taking the same figures for the Crossley engine, which worked at 17 horse-power, we have gas per indicated horse-power 20·55 cubic feet per hour, per brake horse-power 23·87 cubic feet. With the ignition gas added these figures become 20·76 and 24·1 cubic feet per horse-power. These are, however, for the engine only, and do not take into consideration the counter-shaft and fly-wheel which Messrs. Crossley find it necessary to add in order to obtain that regularity of speed which is desirable. The actual consumption of gas, then, including, or rather not deducting this, is for the Crossley engine 27·4 cubic feet per brake horse-power available for electric lighting. The cost of lubricant was equal to that of 1·54 cubic feet of gas per indicated horse-power per hour. The engine converted 22·1 per cent. of the whole of the heat generated into work. Thus, although the well-known excellence of design of this engine and its known durability and steady working secured it a medal, it is not quite so economical as the Atkinson engine, especially when the total gas necessary to drive the second motion shaft and engine is taken into account.

The "Griffin" engine used 22·6 cubic feet of gas per indicated and 28 feet per brake horse-power per hour; with the ignition gas added this reached 22·64 and 28 cubic feet per hour. The lubricant cost the same as 2·72 cubic feet of gas per horse-power per hour. The engine converted into work 21·1 per cent. of the whole of the heat generated. The indicated horse-power of the engine was 15·47, and the brake horse-power 12·5, the mechanical efficiency being thus 80·9 per cent. This engine ran very steadily and uniformly, and from the figures given it will be seen to have been next to the Atkinson engine in economy per horse-power available for electric lighting.

The last engine is the steam engine of Messrs. Davey, Paxman and Co. The results arrived at with this engine confirm in a remarkable degree those obtained by a similar engine by the same firm at the Newcastle trials of the Royal Agricultural Society in 1887. The engine used only 20·74lbs. of steam per indicated horse-power, and 23·08 per brake horse-power. The coal consumed was as low in one trial as 1·79lb. per indicated horse-power, and 2·04lbs. per brake horse-power per hour. The brake used was the rope brake, which the judges say is above suspicion; and hence the cavil which we remember was rather loudly raised against the Newcastle results turns out to be groundless. The engine worked at 19·44 brake horse-power, the indicated power being 22·12, the mechanical efficiency being thus 88 per cent.

In round numbers, then, we may now conclude that it is possible to have a brake horse-power hour from a gas engine for 22·61 cubic feet of gas, including all consumption, or if at 3s. per 1,000, the cost would be 0·8 of a penny per brake horse-power hour. From a compound steam engine we may

Digitized by Google

get the same power, 0·218 of a penny per brake horse-power. These are the results as far as cost of fuel is concerned, and from the remarks of the judges it is clear that any of the engines can be trusted for good continuous work.

REVIEWS.

Le Compteurs d'Energie Électrique. By E. Hospitalier. (Reprinted from *L'Electricien.*) (Paris: G. Masson, 1889.)

At a time when the electricity meter is the subject of so much discussion, the appearance of this little *brochure* is decidedly opportune, although it will, we think, be found that with scarcely an exception the instruments selected for description are either already well-known in this country, or else they are of but little practical importance. Altogether, some eighteen different types are described and illustrated.

Neglecting the mere counters of time (which are nothing more than clock-trains started and stopped as the current is switched on and off), we have first the class of coulomb meters, beginning with the well-known Edison electrolytic cell. M. Hospitalier does not like this type of meter, and in spite of Prof. Forbes's recent certificate we think that his views will find general acceptance in this country. The author's remarks upon this subject are worth quoting. He says:—"The employment of this meter presents some considerable practical difficulties, since it is necessary to change the solution at frequent intervals, and to wash, rinse, dry and carefully weigh the plates, at the house of the client. These troublesome operations (*manipulations fastidieuses*) not only increase the cost of working, but they also fail to give satisfaction to the consumer, and oblige him to rely on the good faith of the company." Mr. Jenks has, however, recently told us that in practice all these difficulties have been completely overcome. We are glad to learn this, but it does not tend to shake our opinion that, other things being equal, a meter which can be read by inspection is to be preferred.

The Ferranti meter is next described, although not so fully as in *The Electrician* of Nov. 23, 1888, p. 71, or by Prof. Forbes in his recent Lecture at the Society of Arts (*Electrician*, Feb. 1, 1889, p. 374). Next we have the Lippmann meter, which is based upon the singular electro-capillary phenomena which M. Lippmann has already turned to good account in other ways. The meter consists essentially of a small rectangular chamber filled with mercury, and lying between the poles of a permanent magnet. The current to be measured passes through the mercury in the chamber. The latter is connected on one side with a reservoir of mercury, and on the other with a tube open at the end, which is curved round and bent over the reservoir. When the current passes the effect is to drive the mercury from the chamber along the curved tube, whence it falls back into the reservoir, thus keeping up a continuous flow, which is proportionate to the current so long as the field is constant. The recording apparatus consists of a balanced trough, divided into two compartments, which tilts to one side or the other as soon as either compartment is filled with mercury. This movement is caused to act on a wheel train in the usual manner. The principle of the instrument is of great scientific interest, but it has never come into actual use. M. Hospitalier says he is not aware of the reason for this neglect, but it is easy to guess that the constant fall of mercury through air results in a considerable loss by oxidation, and also that the presence of the oxide interferes with the freedom of the action. We do not, however, regard this difficulty as insuperable.

The instrument next described is that devised in 1887 by Dr. Werner Siemens. In principle it is identical with the Hookham meter, described in our issue of Feb. 1, 1889, p. 369, but the details are widely different. In each case the measurement is effected by the rotation in a magnetic field of an armature, which is at the same time retarded by the generation of Foucault currents in conducting masses attached to or forming part of it. M. Hospitalier says of the Siemens meter that its proportionality is satisfactory save at the *debut*. This difficulty has been most successfully overcome by Mr. Hookham, whose meter we have seen running at the rate of ten or a dozen turns a minute, and, as we have been assured, without loss of proportionality.

The author next gives an appreciative description of the Forbes meter. He raises a sound but somewhat academic objection to the use of the term coulomb-meter in this connection, on the ground that what the Forbes meter really measures in the case of alternating currents is the square root of the mean square of the currents. This is, of course, just the thing which we want to measure, though it is quite true that it does not represent the coulombs.

After describing the Shallenberger* and the Aron† meter in its latest form, M. Hospitalier refers to an ingenious idea due to Mr. Vernon Boys, which was exhibited so long ago as 1882 at the Crystal Palace Exhibition. The principle involved is briefly that of a horizontal pendulum, or balance wheel, in which the office of the weight, or spring, is supplied by the current to be measured.

The succeeding ten pages are devoted to the Cauderay meter, which ingenious instrument apparently lacks nothing but simplicity of design and construction to render it at least as near an approach to perfection as any other at present in the field. It is, however, difficult to believe that so complicated an apparatus, no matter how beautiful in conception, can compete successfully with some others that might be named. The author makes use of no less than 15 diagrams to describe the three slightly modified types which the inventor has brought out. It must, however, be admitted that though the Cauderay meter has so far met with little success in this country, it appears to do much better in France; indeed, this and the Brillié are the meters now chiefly in vogue in that country. We shall come to the Brillié presently, but we may add here that although it is nearly as complicated as the Cauderay, yet in point of price neither of them compare with others so unfavourably as might perhaps have been supposed.

The author next turns his attention to volt-hour-meters, and he, of course, points out that nearly every meter hitherto described may be adapted to measure volt-hours instead of coulombs. He speaks approvingly of Mr. Wright's use of the depositing cell at Brighton as a shunt on a constant-current circuit (see *Electrician*, December 16, 1887, p. 128), where, of course, it is not open to the same objections as in the case of the chemical coulomb-meter. Mr. Wright, it may be remembered, causes the increasing weight of the deposition plate to move a needle over a divided scale. M. Hospitalier, who is a great purist in the matter of units and nomenclature generally, "protests energetically" (and characteristically) against the barbarous graduation of Mr. Wright's scale in Board of Trade units. We suppose that his excuse would be that his customers know the price they have to pay per B. T. unit, and hence the graduation is such as they can easily appreciate. In fact, we have little doubt that the only reason why Mr. Wright does not graduate his scale in pounds, shillings and pence is because the present tariff may some day be revised; and for our own part we should not be greatly distressed if this graduation were adopted.

We now come to the final division, which comprises the watt-meters. The Weston type is first alluded to, but if we mistake not this instrument has not yet been perfected. The Aron meter, with a shunt coil on the pendulum bob enclosing a solenoid which carries the main current, and another early design of Mr. Vernon Boys, are described and illustrated. Then we come to the Brillié meter of 1888. This instrument has almost as much space devoted to it as the Cauderay, and, as has already been said, it almost equals the latter in complexity. It would be difficult to give an intelligible account of the construction without the aid of diagrams, but our readers may obtain some idea of the instrument from the following quotation:—"The principle of the discontinuously integrating energy meter of M. Brillié consists in ascertaining at regular intervals the reading of a suitable wattmeter, and of integrating the indications so obtained; the action, which is entirely automatic, depends upon the oscillations of a pendulum, the periodical

* *Electrician*, Sept. 7, 1888, p. 556, and Feb. 8, 1889, p. 394.
† *Electrician*, Feb. 15 1889, p. 438.

Digitized by Google

reception of the indications, the movement of the integrator, and the return to the position of rest between two successive operations. The mechanism consists of five principal organs:

"1. An *electro-dynamometer* indicating the power E I which the consumer is employing at the instant of measurement:

"2. An *electro-motor* which drives the whole apparatus:

"3. A *moderator* which regulates the various movements:

"4. A *clock-work train* which determines the interval of time between each successive action:

"5. A *numerator* or *integrator* which registers the sum of the successive values of E I taken at sensible equal periods of time."

Such is the meter of M. Brillié! In the early patterns the record was made at every 36 seconds, but the interval is now increased to one minute.

ON THE DESIGNING OF CONTINUOUS-CURRENT DYNAMO MACHINES.*

BY PROF. JAMIESON, M.INST.C.E., F.R.S.E.

In the short time at the disposal of the author, he proposes to confine his remarks and calculations to "Continuous-Current Constant-Pressure Compound Dynamos," as now used for supplying current to ordinary incandescent lamps arranged upon the parallel system. . . . It is not our intention to enter here into the many mechanical and electrical arrangements of dynamos, or to trace the manner in which dynamos have been gradually simplified and cheapened. . . .

Let E_a represent the electrical pressure generated in the armature.
E_e ,, external electrical pressure, or that available for useful work.
R_i ,, internal resistance of the whole dynamo.
R_e ,, external resistance of leads and lamp circuits.
C_a ,, current passing through armature.
C_e ,, current external, or that sent through lamp circuit.

Then, $$C_a = \frac{E_a}{R_i + R_e} = \text{total current generated.}$$

And, $$C_e = \frac{E_e}{R_e} \text{ external current.}$$

The electrical efficiency $= \frac{C_e \times E_e}{C_a \times E_a} = \frac{\text{output in watts}}{\text{total watts generated}}$.

Now, since C_a, E_e, and C_e depend directly upon E_a, we propose to show how this internal electrical pressure may be obtained for any dynamo of the kind under consideration.

This total or internal pressure, E_a, depends entirely upon—

1. The total number of magnetic lines which flow between the field-magnet poles through the armature.
2. The total number of convolutions of the armature conductors which are in series at one time.
3. The speed of rotation of the armature.

The *number of revolutions* per minute is a matter that can be easily decided upon before beginning to design the dynamo. Fast speed dynamos, if well balanced, are common in land installations; slow speed ones on board ship, and when vibration and noise must be avoided.

The *number of convolutions* of the armature conductor depends upon the number of radial bars in the commutator, the diameter of the armature, and the size of wire to be used, all of which will be determined as the drawing or design proceeds in accordance with sound practice.

The *magnetic circuit* is the chief and most intricate part of the whole design which requires our attention, and we shall therefore consider it first in full detail.

I.—*Field-Magnet Circuit.*

The field-magnet circuit should have as little magnetic resistance as possible. The magnet cores, &c., *should* therefore be made of the best soft Swedish iron, short, of large sectional area, and with no joints. Owing, however, to expense, the difficulty of winding the wire on the magnets, or the fixing of bobbins containing the wire, and the necessity of having sufficient residual magnetism with which to start the dynamo current, and to prevent fluctuations of current, the yoke (if there is one) and the pole-pieces are frequently made of cast iron.

* Paper read before the Institution of Engineers and Shipbuilders in Scotland, on 22nd January, 1889.

In a Kennedy dynamo (*see* Fig. 1), the mean length of the magnetic circuit indicated by the letter L_m, and the poles are marked N and S.

II.—*Air Spaces.*

The air spaces should have the least possible magnetic resistance. They should therefore have as little depth as is consistent with preventing actual contact between the armature wires and the pole-pieces, and of allowing free circulation of air, and of preventing heating of the pole-pieces due to Foucault or eddy currents in the forward ends of the pole-pieces.

In Fig. 1 the two air spaces are marked L_{as}, L_{as}.

III.—*Armature Core.*

The armature core should have as little magnetic resistance as possible, and be as free as possible from inducing Foucault currents. It should therefore be built up of the softest thin Swedish iron plates, well insulated from each other, and laminated or placed in a direction parallel to the direction of the magnetic lines passing between the poles of the field-magnet. Some makers prefer to build up their armature cores of soft iron wire insulated by the natural thin coating of oxide of iron always found on such wire.

In Fig. 1 the mean directions of the split magnetic circuit through the armature core are marked L_a, and L_a.

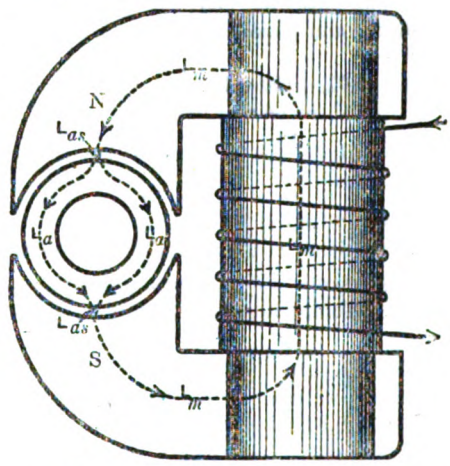
IV.—*Magnetic Resistance of Field-Magnet Circuit.*

The magnet circuit L_m has a magnetic resistance

$$R_m = 2\frac{L_m}{S_m},$$

where

2 = Kapp's coefficient for the initial specific magnetic resistance of soft wrought iron (the number 3 to be used if core, &c., be of cast iron).
L_m = the mean length of field-magnet circuit in inches.
S_m = sectional area in square inches (at right angles to L_m) of magnet core.



Magnetic Circuits of a Single-Bobbin Kennedy Dynamo.

V.—*Magnetic Resistance of Air Spaces.*

The air spaces circuits L_{as}, L_{as} have a resistance

$$R_{as} = 1440\frac{2\,L_{as}}{S_{as}},$$

where

1440 = Kapp's coefficient for the specific magnetic resistance of air and copper when wrought-iron magnets are used (1800 to be used with cast-iron magnet cores and pole-pieces, and 1500 with wrought-iron cores and cast-iron poles).
L_{as} = depth of each air space in inches (and since there are two spaces, 2 L_{as} is inserted in the formula).
S_{as} = sectional area of each air space or surface area of each pole-piece in square inches.

VI.—*Magnetic Resistance of Armature Core.*

The armature core circuits L_a, L_a have a magnetic resistance

$$R_a = \frac{L_a}{S_a},$$

where

L_a = mean average length of armature core magnetic circuit in inches (if there was only but one path instead of two we should have to multiply by the coefficient 2, as in equation (IV.), but $2\frac{L_a}{2} = L_a$).

S_a = cross sectional area of armature core in square inches = twice radial depth × length of armature core

Digitized by Google

VII.—*Total Magnetic Resistance.*

The total magnetic resistance of the complete magnetic circuit is therefore—

$$R_m + R_{as} + R_a = 2\frac{L_m}{S_m} + 1440\,\frac{2\,L_{as}}{S_{as}} + \frac{L_a}{S_a}.$$

VIII.—*Kapp Lines.**

The total number of Kapp lines, K, of magnetic force which pass through the magnet and air space can therefore be calculated by *dividing* the ampere-turns ($A \times T_{mw}$) on the magnet windings by the total magnetic resistance in the magnetic circuit.

Or
$$K_L = \frac{A \times T_{mw}}{R_m + R_{as} + R_a},$$

i.e.,
$$K_L = \frac{A \times T_{mw}}{2\,\frac{L_m}{S_m} + 1440\,\frac{2\,L_{as}}{S_{as}} \times \frac{L_a}{S_a}}.$$

IX.—*E.M.F. in Armature.*

The E.M.F. developed internally in the armature winding is—

$$E_a = K_{La} \times T_{aw} \times N_{ar} \times 10^{-6},$$

where

E_a = E.M.F. developed in armature in volts.
K_{La} = Kapp lines which only pass through armature or the useful field.
T_{aw} = turns of armature wires in series (counted all round core).
N_{ar} = number of armature revolutions *per minute*.

Example I.†—Let us now apply the foregoing formulæ to the design of a single-field compound dynamo.

Let the dynamo be furnished with a long shunt, and be of 6,400 watts (external power, P_W), when driven at 1,000 revolutions per minute.

First, let us determine the resistance, current, fall of potential, in armature and magnets, and percentage loss of power in the armature, shunt, and main field-magnet coils, using the same symbols as before.

Given $E_e = 100$ volts.
$C_e = 64$ amperes.

Resistances—Then $R_e = \frac{E_e}{C} = \frac{100\,v}{64\,a} = 1{\cdot}55$ ohm.

Suppose we agree to a loss of about 10 per cent. of the total power in the dynamo, or say—

The electrical efficiency of the dynamo = 90 per cent.

$\therefore$ 90 per cent. : 100 per cent. :: 6,400 P_W : x.

$\therefore$ Total power = x = 7,100 P_W.

Let $R_a = \frac{R_e}{20} = \frac{1{\cdot}55}{20} = {\cdot}077\ \omega.$

Let $R_s = R_a \times 1{,}000 = {\cdot}077 \times 1{,}000 = 77\ \omega.$

Let $R_m = 75\%\ R_a = \frac{3}{4} \times {\cdot}077 = {\cdot}058\ \omega.$

Now, the external current = current in armature and field-magnet main coils less the current in shunt.

Currents.—Or $C_e = C_a - C_s.$

But, $C_s = \frac{E_e}{R_s} = \frac{100v}{77\ \omega} = 1{\cdot}3\,a;$

$\therefore$ $64\,a = C_a - 1{\cdot}3\,a,$

$C_a = 64 + 1{\cdot}3,$

$= 65{\cdot}3$ amperes.

Fall of potential in armature $= C_a \cdot R_a = 65{\cdot}3 \times 0{\cdot}77.$

$= 5{\cdot}02$ volts.

Fall of potential in magnet main coils $= C_m \cdot R_m = 65{\cdot}3 \times {\cdot}058$

$= 3{\cdot}78$ volts.

Total fall of potential in armature and magnet series coils.

$= C_a$ or $C_m\,(R_a + R_m)$

$= 65{\cdot}3\,({\cdot}077 + {\cdot}058) = 8{\cdot}8\ v;$

$\therefore$ $E_a = 8{\cdot}8 + E_e = 108{\cdot}8$ *volts.*

Percentage losses of power.—

In armature $= C_a^2 \cdot R_a = 65{\cdot}3^2 \times {\cdot}077$

$= 330\ P_W;$

$\therefore$ 7100 P_W : 330 P_W :: 100 : x_a.

$x_a = 4{\cdot}63$ per cent.

In shunt coils $= C_s^2 \cdot R_s = 1{\cdot}3_a{}^2 \times 77\omega$

$= 132\ P_W;$

$\therefore$ 7100 P_W : 132 P_W :: 100 : x_s.

$x_s = 1{\cdot}86$ per cent.

In main coils $= C_m^2 \cdot R_m = 65{\cdot}3^2 \times {\cdot}058$

$= 248\ P_W;$

$\therefore$ 7100 : 248 :: 100 : x_m.

$x_m = 3{\cdot}5$ per cent.

Totalling the different percentage losses we have :—

In armature..... $x_a = 4{\cdot}63$ per cent.
In shunt coils..... $x_s = 1{\cdot}86$,,
In main coils ..... $x_m = 3{\cdot}5$,,

$9{\cdot}99$ %, or, say, 10 %.

Kapp Lines in Armature Core.—Now, before substituting the above data in Kapp's formula, we must agree upon the turns of wire in the armature at the agreed upon 1,000 revolutions per minute. Let there be 36 commutator bars of 36 sections of wire in armature, which has been found sufficient to give a current of practically uniform E.M.F. The number of turns of wire in each section of the armature depends upon whether we use double or single winding, and upon the current and the resistance of the armature wire. As we shall see further on, from our trial drawing and calculations we can get in six turns of wire to each section.

$\therefore$ $T_{aw} = 36 \times 6 = 216$ turns of armature wire.

Let $N_{ar} = 1{,}000$ revolutions per minute.

Now $E_a = K_L \times T_{aw} \times N_{ar} \times 10^{-6}.$

$\therefore$ $K_{La} = \frac{E_a}{T_{aw} \times N_{ar} \times 10^{-6}}.$

$= \frac{108{\cdot}8\ v}{216 \times 1000 \times 10^{-6}} = 503{\cdot}7,$

say = 500 Kapp lines in *armature core.*

In order to obtain a certain number of Kapp lines or magnetic induction in an armature, core it is necessary to give a greater magnetic intensity to the field-magnet core or cores, owing to the unavoidable leakage of magnetic lines which do not pass through the armature core.

Dimensions of Magnet Core.—In ordinary practice it is usual to assume that only about 80 per cent. of the field-magnet lines pass through the armature core.

Therefore, the Kapp lines in *field-magnet* are—

80 per cent. : 100 per cent. :: 500 : $x = 625$.

We must now ascertain the dimensions of the field-magnet core to carry these 625 Kapp lines. Suppose we consider the case of field-magnets to be cast iron throughout (poles and core).

A safe working density is 9 Kapp lines per square inch

$\therefore$ $S_m = \frac{625}{9} = 69{\cdot}4$ square inches.

$= 9{\cdot}4$ inches diameter (if round).

In practice it is found that a dynamo magnet bobbin should be in length about $1\frac{1}{4}$ times its diameter to give the necessary space for winding or ampere-turns.

$\therefore$ $9{\cdot}4 \times 1{\cdot}25 = 11{\cdot}75$ inches long.

Dimensions of Armature Core.—It has been found advisable, in designing the dimensions of the armature core of a dynamo having a field-magnet of the form we are now considering, to make the diameter of its core slightly larger, and its length slightly less, than the diameter of the field-magnet core.

Therefore, calling the diameter of the gramme armature core 10 inches, its length 9 inches, and allowing a density of 20 Kapp lines per square inch of core section, since it is made of the best permeable wrought iron,

we have $\frac{500}{20} = 25$ square inches total cross section of armature.

$\therefore$ $S_a = 25$ square inches.

Allowing 20 per cent. of total space for insulation between *laminated plates* in armature core, we have

80 per cent. : 100 per cent. :: 25 : $x = 31{\cdot}5$ square inches;

$\therefore$ $\frac{31{\cdot}5}{2} = 15{\cdot}75$ square inches in each half.

$\therefore$ $\frac{15{\cdot}75}{9''} = 1{\cdot}75$ inch = radial depth of core.

* A Kapp line is simply = 6.000 C.-G.-S. magnetic lines.
The number 6,000 is made up of two terms, viz., 60, which enables revolutions to be counted per minute instead of per second; and 100, to bring down the measurement of the magnetic lines to reasonable numbers; or $\frac{\text{C.-G.-S. lines}}{60 \times 100} = \frac{\text{C.-G.-S. lines}}{6000}$. Then, 1 Kapp line = 6,000 C.-G.-S. lines.
Since there are 6·4514 square centimetres in a square inch,
1 Kapp line per sq. inch = $\frac{6000}{6{\cdot}4514} = 930$ C.-G.-S. lines per square centimetre.

† The calculations for Example I. were made by Boucher's Calculator, and thus are therefore only approximately true.—A. J.

Digitized by Google

Magnetic Resistance of Field-Magnet.—Now, drawing armature and field-magnets to scale (as per Fig. 1), and allowing 2½ inches for depth of winding on field-magnet bobbin and clearance for armature, we find the mean length of field-magnet core $L_m = 44$ inches, and remembering that in a formula for the magnetic resistance of this part of the circuit we have to use a coefficient of 3 instead of 2, seeing that the core is of cast iron,

we have
$$R_m = 3\frac{L_m}{S_m}$$
$$= 3\frac{44}{69{\cdot}4} = 19.$$

Magnetic Resistance of Air Space.—With *two* layers of insulated conductors having a cross-section (⌐¬) of ·08 inch deep, by ·2 inch broad (including covering), we find the total depth of air space on one side between pole-pieces and armature core (allowing ·14 inch mechanical clearance), equal ·3 of an inch.

Consequently, $2\,L_{as} = 2 \times {\cdot}3 = {\cdot}6$ inch.

The bore of pole-pieces will be = diameter of armature core + $2\,L_{as}$
= 10 inches + ·6 inch = 10·6 inches.

It is good practice to allow the corners of pole-pieces to form an angle of 30° with centre of armature. The angle embraced by each pole-piece will therefore be 180° − 30° = 150°, which gives us a circumferential length of say 14 inches for each pole. And since our armature core is 9 inches long, and it is unusual to make the pole-pieces broader than this length, we have

$S_{as} = 14$ inches × 9 inches = 126 square inches.

Hence
$$R_{as} = 1800\frac{2\,L_{as}}{S_{as}}$$
$$= 1800\frac{2 \times {\cdot}3}{126} = 8{\cdot}5.$$

Magnetic Resistance of Armature.—Referring to scale or full-size section, we find by measurement that $L_a = 15$ inches. We have already determined S_a to be 25 square inches;

consequently,
$$R^a = \frac{L_a}{S^a}$$
$$= \frac{15}{25} = {\cdot}6.$$

$$\therefore\ R_m + R_{as} + R_a = 1{\cdot}9 + 8{\cdot}5 + {\cdot}6$$
$$= 11 \text{ Kapp units of magnetic resistance.}$$

Ampere Turns.—From formula for *cast* iron, under heading VIII.

$$K_L = \frac{A \times T_{mc}}{R_m + R_{as} + R_a} = 625 \text{ (gross Kapp lines)}$$

$$\therefore\ A \times T_{mc} = K_L\,(R_m + R_{as} + R_a),$$
$$= 625 \times 11,$$
$$= 6875 \text{ total ampere-turns in shunt and main field-magnet coils.}$$

(To be continued.)

THE PHYSICAL SOCIETY.

ANNUAL GENERAL MEETING.

At the annual general meeting of this society, held on February 9, Prof. Reinold, president, in the chair, the reports of the Council and treasurer were read and adopted. From the former it appears that the number of members has only slightly increased during the year, due, it is supposed, to the advantages offered by the Society not being generally known, and a fly-leaf has been prepared, giving a short account of the Society's objects and procedure, copies of which may be obtained from the secretaries. During the past year Vol. I., Part 1, of "Physical Memoirs Selected and Translated from Foreign Sources," has been printed and issued to members; and the translations of important memoirs by Fourier, Hittorf, and Volta are well advanced, and will be published shortly. The treasurer's report showed the financial position of the Society to be very satisfactory. Owing to the lamented death of Prof. Clausius, a vacancy has occurred in the list of honorary members, to fill which Prof. R. W. Bunsen was nominated by the Council and duly elected. The following gentlemen were elected to form the new Council:—President: Prof. A. W. Reinold, F.R.S.; Vice-Presidents: Dr. E. Atkinson, Prof. W. E. Ayrton, F.R.S., Shelford Bidwell, F.R.S., the Right Hon. Lord Rayleigh, Sec.R.S.; Secretaries: Walter Baily, Prof. J. Perry, F.R.S.; Treasurer: Prof. A. W. Rücker, F.R.S.; Demonstrator: C. Vernon Boys, F.R.S.; other members of Council: Hon. R. Abercromby, T. H. Blakesley, W. H. Coffin, Conrad W. Cooke, Prof. O. Lodge, F.R.S., Prof. W. Ramsay, F.R.S., W. N. Shaw, Prof. S. P. Thompson, H. Tomlinson, and Dr. G. M. Whipple. Cordial votes of thanks were passed (1) to the Lords of the Committee of Council on Education for the use of the rooms and apparatus of the Normal School of Science: (2) to the Council and officers of the Society for their services during the past year; and (3) to the auditors, Mr. Inwards and Prof. Minchin, for examining the accounts. In returning thanks for the Council and officers the President attributed the great success of their meetings to the indefatigable zeal displayed by the Hon. Secretaries.

At the following meeting, on February 23, Prof. AYRTON gave an account of a Paper by Prof. Perry and himself on

Electrical Measurement.

The Professor observed that it is well known that the change in the resistance of a galvanometer owing to the heat produced by the passage of a current through it is of no importance when the galvanometer is used as an ammeter, but becomes of importance when it is used as a voltmeter. The authors had therefore endeavoured to determine mathematically the law according to which both the thickness and the material of the coils of their magnifying-spring voltmeter should vary with the diameter of each convolution in order that the heating should be a minimum, and the results were communicated to the Society in 1885. They found that copper wire should be used in preference to German silver wire throughout, and that the thickness of each convolution should be proportional to the radius raised to the power 0·42. Practically their magnifying-spring voltmeters are made with three or four different thicknesses of wire, as it would not be convenient to vary the thickness for every layer.

In making the calculations fairly simple laws were assumed for the variation of the magnetic effect of a convolution with its distance from the soft iron cylinder, and for the variation of the thickness of the silk covering with the thickness of the wire.

Since then the substance platinoid had been obtained, having a temperature coefficient less than half that of German silver, and some experiments on phosphor-bronze made at the Central Institution had shown that it varies its resistance only 0·08 per cent. per degree C., and that the resistance of a cubic centimetre at 0° C. is only 9·7 microhms, as compared with 1·6 microhm for copper.

The authors find that for a voltmeter wound with wire of the same gauge throughout, an approximation to the heating error can be obtained for wire of any material, of any diameter, with any thickness of insulating covering, and they find that the number of watts which must be expended to produce a given deflection is proportional to the product of the specific resistance of the material by the square of the ratio of the diameter of the covered to the uncovered wire. Now, for fine wire this ratio is greater than for thicker wire, and therefore a voltmeter wound with fine wire for the measurement of high voltages will become hotter than one wound with thick wire. They prove, in general, the fact that, as was first suggested to them by Mr. Crawley, the number of volts which must be maintained between the terminals of a voltmeter of a given type, whatever the material and diameter of the wire with which it is wound, and whatever the thickness of the insulating material, is simply proportional to the resistance per centimetre of the wire.

Let a be the coefficient of increase of resistance per degree centigrade of the wire with which the voltmeter is wound, S the cooling surface of the instrument in square centimetres, e the rate of loss of heat in watts per square centimetre per degree of excess of temperature of the instrument above that of the room, ρ_0 the resistance of the wire per cubic centimetre at 0°C. K is a constant depending on the construction of the instrument, and D and d are the diameters of the covered and uncovered wires respectively. Then the authors find that the percentage heating error due to a continued maintenance of the P.D. at the terminals of the instrument is

$$\frac{100}{\frac{S\,e}{a\,\rho_0\,K} \cdot \frac{d^2}{D^2} - 1}.$$

Consider four voltmeters exactly similar as regards size, shape and magnifying spring, wound respectively with copper, German silver, platinoid and phosphor bronze, the wire in each case being of such a diameter that the same number of volts maintained at the terminals of each instrument produces the same deflection; that is, let the resistance per unit length of each wire be the same in each case, irrespective of the thickness of the insulating covering. Then, if the diameter of the copper wire be 5 mils (thousands of an inch) the others will be

German silver ..... $5\sqrt{\frac{21}{1{\cdot}6}}$ = 18 mils nearly.

Platinoid ..... $5\sqrt{\frac{34}{1{\cdot}6}}$ = 23 mils nearly.

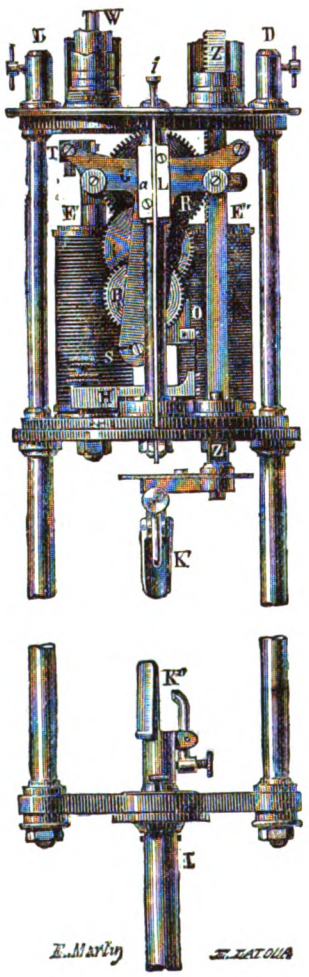
Phosphor bronze ..... $5\sqrt{\frac{9{\cdot}7}{1{\cdot}6}}$ = 12 mils nearly.

Digitized by Google

Now the authors find that for wires of diameters varying (when uncovered) from 3 to 50 mils, the thickness of the silk covering increases the diameter by about 3 mils in each case, and therefore the values of $\frac{d}{D}$ are $\frac{5}{8}$ for copper, $\frac{18}{21}$ for German silver, $\frac{23}{26}$ for platinoid, and $\frac{12}{15}$ for phosphor bronze, in order that the same voltage may produce the same deflection, and hence they find the values of $\frac{1}{\alpha \rho_0} \cdot \frac{d^2}{D^2}$ to be $6{\cdot}106 \times 10^7$ for copper, $7{\cdot}952 \times 10^7$ for German silver, $11{\cdot}21 \times 10^7$ for platinoid, and $8{\cdot}046 \times 10^7$ for phosphor bronze; so that if these substances be arranged in diminishing value for use in voltmeters as regards the heating error, they stand platinoid, phosphor bronze, German silver, copper. If, however, the range of all four voltmeters be such that a 10 mil copper wire would be the right gauge to use in the case of the copper, then the authors find that the materials arrange themselves in a slightly different order—viz., platinoid, phosphor bronze, copper, German silver, the German silver in this case being the worst metal to use.

THE FEIN ARC LAMP.*

In the Fein lamp there are two electro-magnets, E′ and E″, the cores of which are attached to the extremities of the cross-piece of the frame G, and a series of clockwork wheels arranged inside this



T-shape frame. The electro-magnet E′ is wound with thick wire, and is in series with the main circuit; the electro-magnet E″ is wound with fine wire, and is a shunt upon the arc. The frame G is supported by the plates L, and it oscillates round the axis of the wheel R, which engages with the rack Z. The rotation of the last wheel B is stopped by the brake O, which is connected to one end of a flexible strip of metal, the other end of which is attached to H. The position of H is regulated by means of the screw S. When the circuit is closed the action of the electro-magnet E′ preponderates, it attracts its core, and causes the frame G to oscillate from right to left; this brakes the wheel B and raises the rod Z, striking the arc. As the carbons consume away the action of the electro-magnet E″ becomes preponderant, the frame G oscillates in the reverse direction, and the rod Z is allowed to fall. If by any chance the arc is broken the current in the coils of the solenoid E″ attains a maximum, and the contact T is pressed against the upper plate of the lamp, completing the circuit through W, a resistance equal to the working resistance of the lamp. The remaining lamps in circuit are therefore in no way affected.

LEGAL INTELLIGENCE.

King, Brown and Co. v. The Anglo-American Brush Electric Light Corporation (Limited).

The evidence of Charles Francis Brush, of Cleveland, Ohio, taken by commission in America on behalf of the defenders in this action, has now been reported to the Court of Session. He deposed that he was thirty nine years of age, and for the past twelve years had given a great deal of study and attention to electrical science. He was the person referred to in letters patent No. 2003 of 1878. He claimed to be the first inventor of the invention there described, and he communicated it to Herbert John Haddan. To the best of his knowledge and belief the invention was novel in the United Kingdom at that date. *Q.* State generally the state of knowledge in England or America as to the systems of winding the magnets of dynamo machines in 1878?—*A.* At that time dynamo electric machines were used principally for two purposes—electric plating and electric lighting by means of the arc system. Prior to the date of my invention it was customary to construct dynamo-electric machines for both of the purposes above specified on the series plan. Some of the earlier plating machines had their field-magnets excited by a separate magneto electric machine. The shunt dynamo was not then known. The state of electrical knowledge as to the construction of incandescent lamps was exceedingly crude, and no incandescence lamp of a practical or commercial nature had been produced. These prior dynamos were unsuited for incandescence lighting in parallel arc, because of their inability to maintain a substantially or sufficiently constant potential with varying amounts of work in their external circuits. They could not operate normally a small amount of work as well as a large amount of work. The object of his invention was the production of a dynamo electric machine that would automatically maintain a substantially or sufficiently constant potential under varying amounts of work in its external or working circuit. While in his specification he had quite fully described the suitability of his dynamo for operating electro-plating baths, he did not in any degree intend to limit it to such a use, and in support of this he quoted from the specification of the Haddan patent:—"It will now be obvious that if even a moderately strong magnet field be constantly maintained within the machine both of the above-described difficulties will be eliminated. Other useful applications of a permanent field machine will readily suggest themselves." It was apparent to him that his dynamo was eminently suitable for other uses than that of electro-plating, and in the language quoted he had designed to state that fact. His dynamo was of great value for incandescent lighting, because of its ability to maintain automatically a substantially and sufficiently constant electromotive force, and to automatically and normally do varying amounts of work, from great to small, upon its external or working circuit. To successfully do that a constant potential dynamo electric machine, such as his patent described, and such as he believed he had successfully produced for the first time, was necessary. *Q.* When did a demand for machines with constant electromotive force first spring up.—*A.* The want of such machines was felt prior to my invention, and it was the recognition of this want that led me to produce the invention. Promptly after, and continuously since, the production of his constant-potential dynamo there had been an active demand for such machines. The active commercial demand for constant potential dynamos could not be said to precede their existence, and he should say that the demand for these machines first sprang up after his invention. He first began to make machines according to his specification in the latter part of 1876 or early in 1877, and continuously since that time the Brush Electric Company of Cleveland, Ohio, had supplied the market demand for such machines. He had made many tests of the machines made by him, and on August 4, 1882, he sent to Mr. Swinburne definite reports and data of tests made prior to that date. The data were made as follows:—

No. 7 Machine.—Speed 800 revolutions per minute.

Current. Amperes.	E.M.F Volts.
13·9	87·57
44·3	90·09
73·3	88·83
93·4	80·64
100·1	67·2

No. 5 Machine.—Speed 865 revolutions per minute.

2·7	147·55
4·2	149·3
5·7	151·9
8·8	149·12
10·8	150·10
17·2	149·64
19·5	141·57

No. 2 Machine.—Speed 1,180 revolutions per minute.

Currents. Amperes.	E.M.F. Volts.
3·6	22·64
7·15	24·38
17·8	22·78
24	22·56
26·7	20·8
27·6	16·56

Witness gave the records of other tests made in December, 1884, with incandescent machines. He could not give the exact number of his dynamos that had been sold up to the present time, but it reached many hundreds.

The witness was then asked to explain the action of the double winding, which he did at some length. Continuing, he said that he now made dynamos for lighting in parallel and in "shunt series" or compound-winding. The requirements for electro-plating were analogous to those of incandescent lighting in parallel. He believed the directions in the specification describing his invention were abundantly sufficient to enable any workman reasonably skilled in the art to which that invention appertained at the date of the Haddan patent to have made and practised the invention without the exercise of anything more than ordinary mechanical ingenuity on his part. He had carefully examined Varley's patent, No. 4,9[illegible]5 of 1876, and he did not find disclosed therein anything which at the date of the Varley patent would suggest to a skilled workman the arrangement and connection of field coils now known as compound-winding, and specifically shown and described in the Haddan patent. Being specially referred to a portion of the Varley patent, which stated that there were several ways of diverting "part of the electricity developed by the machine to maintain the magnetism of the soft iron magnets, and the remaining portion is used to produce the electric light," witness said the only well-known way, so far as he was aware, at the date of the Varley patent of energising the field-magnets of a machine aside from the use of a separate and independent current for that purpose, was by putting them directly into the circuit of the armature and external work. The writer in what had been quoted might have intended to express the idea that a part of the electrical energy developed by the machine was used to maintain the magnetism of the field-magnets, while the remaining portion of the electrical energy was used to do external work, that was to operate an electric light; but that theory of the meaning of the lines was not compatible with other portions of the specification. The writer said:—"But the method I prefer is to wrap the soft iron magnets with two insulated wires, one having a larger resistance than the other. The circuit of larger resistance is always closed, and the circuit of less resistance is used for the electric light." In the light of their advanced knowledge of dynamo electric machinery at the present date these words might be said to hint at what was known as a series-shunt winding; but considered in the light of the state of the art which obtained at the date of the Varley specification, they might mean that or several things. The drawings, in fact, showed simply a series winding. In the Varley patent the writer says:—"When we use four electro-magnets we employ two commutators and four bobbins. Two of these bobbins and one commutator are arranged on the axle at right angles to the other bobbins, and commutator and electro-magnets are wrapped with a double series or convolutions of silk or cotton-covered wire, insulated from one another. One set of convolutions of insulated wire of the four pairs of electro-magnets is connected to one commutator, and the other set is connected to the other commutator." The writer there had evidently in view a double-series machine—that was, a machine producing from one armature two distinct currents, each having its own commutator, and each current energising a separate set of field coils on the magnets. The reason for the arrangement as to the bobbins was sufficiently obvious. Each pair of bobbins produced what was known as an alternating current, the alternations of which, being corrected by the commutator, produced a pulsating current—that was, a current consisting of waves or pulsations rising from nothing to a maximum, and quickly dropping to nothing again, and so on. Such pulsating current was not well adapted to energise field-magnets, because the magnets partially demagnetised themselves between the current pulsations. By means of the arrangement of the two pairs of bobbins at right angles with each other, the maximum strength of each pulsation of one of the currents produced by the machine would occur at a point of time between the corresponding periods of the other current, and would thus, so far as the excitation of the field-magnets was concerned, bridge over the gap, so to speak, in the other pulsating current, and render the resultant magnetising effect of the two currents more nearly uniform than would be possible with either current separately. It seemed to him a possible explanation of the language in Varley's patent might be that the writer intended to secure a machine, with its commutators and armature bobbins so arranged as to produce two separate and independent currents, one of which was caused to flow through the magnet circuit of low resistance and the arc lamp external to the machine, and the other of which was caused to flow through the magnet circuit of higher resistance and the helices of the lamp motor external to the machine. At the date of Varley's patent there were several well-known ways of diverting a portion of a current for one purpose, and at the same time using the remainder of the current for another purpose. So far as he recollected, the methods of diverting a part of a dynamo-current to excite the field were those of Ladd and Wilde, by the employment of separate armatures; also by Wilde's method of employing some of his armature bobbins to excite the field, and Rhumkorff's double-wound armature. Clark also, in his patent, No. 4,311 of 1875, indicated a form of simple-shunt dynamo, which also fulfilled the purpose suggested. Even at the present time there was only one known method of compounding a machine. He considered the so-called "long-shunt" and "short-shunt" as being but slightly differing modifications of each other. In the drawings of the Varley patent he found no indications of the way in which the wire of greater resistance was to be connected. There was only one wire, and that in series with the armature, and arranged to carry the whole current of the machine. It appeared to him that Varley's "wire of greater resistance" was intended to do work outside of the machine, that work consisting in operating the electro-motor of the lamp mechanism.—*Q.* Is that consistent with compound winding?—*A.* It might be if Varley's fine wire circuit external to the machine was kept constantly closed and of constant resistance, and his lamp motor worked with a constant load. The language of the Varley patent seemed to him more consistent with some arrangement of circuits other than compound winding. It appeared to be the fact that Varley cut his bobbins out of the circuit for a considerable time when they were acquiring or losing a very considerable amount of magnetism. The effect of that would be to produce violent sparking, and would, in his opinion, be quite fatal to any practicability which the machine might otherwise have. Varley's improvement appeared to have been founded upon a misconception of the principles involved in the generation of currents in dynamo-electric machines, and witness did not see how, under any circumstances, his apparatus, as described in the specification, so far as it was intelligible, could have been in any sense a practical or useful one. He considered Varley's patent, taken as a whole, to be so ambiguous, incomplete, and uncertain as to be impossible of any satisfactory or consistent explanation. He did not consider Varley's machine an improvement of any value upon any form of dynamo in existence at the date of his patent. There was nothing in Varley's patent to show that his two wires were intended to act simultaneously, and to augment each other's effect on the magnets. The object of the insulating segment in witness's commutator was to cut out of circuit at the proper time the two armature bobbins with which it was associated. That was done by simply opening the circuit of these bobbins through the agency of the insulating commutator segment, and one segment was as effective for that purpose as more than one could be; and for the sake of simplicity he used but one insulating segment for each set of armature bobbins. The advantages of thus making the commutator had especial reference to simplicity, durability, and facility of repair. By providing the detachably-attached segments the entire wearing parts of the commutator could be quickly, accurately and cheaply renewed whenever necessary without any disintegration of the machine, and without any disturbance of the permanent electrical and mechanical connections between the commutator and the balance of the apparatus. The disadvantages of the forms of commutators in use at the date of Haddan's specification resided in the necessity of more or less disintegrating the dynamo whenever it became necessary to renew the commutator segments when too much worn. Shown Clark's specification, No. 4,311 of 1875, witness said Clark's dynamo was a closed-coil armature machine, which necessitated the Gramme form of commutator, while the Haddan dynamo was of a fundamentally different type, now known as the "open-coil armature" type of machine. In detail of construction there was no similarity whatever between the Clark and Haddan dynamo. In the Paper which he read before the Royal Society on the 14th February, 1867, Sir Charles Wheatstone described as the best arrangement of his experimental apparatus what was now known as a "simple-shunt" wound machine. Wheatstone appeared to have used his apparatus in some experiments as a "series-wound" machine, and in others as a "shunt-wound" machine. In no experiment detailed in Wheatstone's Paper did he employ both systems simultaneously, or hint at the possibility of such combined employment in any form of machine. Even with their present knowledge of "compound winding," the apparatus described by Wheatstone could not be made to embody the principle of "compound winding," because Wheatstone's field-magnet was provided with only one coil of wire.

(To be continued.)

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *February 16th*, 1889.

On the evening of Feb. 4th Mr. W. J. Hammer, who is so well known in connection with the work of Mr. Edison, delivered a lecture on "Edison and His Inventions," before the Franklin Institute, Philadelphia. In view of the fact that the number of Mr. Edison's inventions or patents reaches nearly 600, to say nothing of 300 that are in progress, it is not to be wondered that a large and varied field was traversed by Mr. Hammer in the course of his remarks. The difficulty of selecting the points of greatest interest was overcome most successfully, and the lecture embodied a remarkably able description of the principal Edison inventions in the field of telegraphy, telephony, phonography, electric lighting, &c., all of which were made clear by numerous illustrations and experiments. A striking and suggestive exhibition was given of the possibilities in the combined use of the telephone and phonograph, and telephone conversation, music, &c., were transmitted and recorded under varying conditions. A cornet solo was transmitted from a

Digitized by Google

phonograph attached to the telephone in New York, and the notes could be heard as distinctly as if the phonograph had been in the same room as its auditors. This experiment was repeated three times, the same roller in the same phonograph in New York being used to show that the instrument could repeat itself indefinitely. The third performance was as successful as the first. Then a phonograph was attached to the telephone at the Philadelphia end of the line and a New York phonograph a fourth time repeated its cornet solo, the telephone receiver being held within a few inches of the long funnel which carried the sounds into a phonograph on the table. The Philadelphia phonograph then reproduced the music for the benefit of the audience, and while the sounds were somewhat fainter than when heard from the telephone, they were still distinct. This was a reproduction of music at fourth hand. First it had been played into the New York phonograph, then transmitted over the telephone to the phonograph in Philadelphia, and then given to the audience. This wonderful experiment was accomplished by means of two phonographs, two Edison carbon transmitters, and two Edison motograph receivers or loud-speaking telephones acting through 103 miles (the distance between New York and Philadelphia) of telephone wire, six miles of which were underground.

A most instructive and interesting meeting of the New York Electrical Society was held in the evening of February 6, when the Society visited the factory of the C. and C. Electric Motor Company, in this city, on the invitation of the company. The American Institute of Electrical Engineers were the guests of the Society, and over 150 persons were present. Mr. Harvey L. Lufkin embodied in a short address a description of the working of the factory, which being a new departure in the application of power has attracted great attention here. In the course of his remarks Mr. Lufkin said: "Our average load on the dynamo, which is a 50,000 watt machine of 220 volts E.M.F., is about 40 amperes, or about 12 electrical horse-power, which covers both light and power. The friction load on the engine is 6·4 horse-power, giving us a total of about 20 to 22 horse-power in the engine. The power which would be necessary to operate our factory in the usual way, by belting through the floors, was estimated by several engineers competent in factory construction to be between 30 and 50 horse-power, without considering the power required for our lights, amounting to an additional 15 horse-power; in other words, we are delivering an estimated 50 to 70 horse-power, and only developing from 15 to 30 horse-power, with an average of but 17 to 18 horse-power for ten hours. Every machine on our factory bears exactly this relation to the engine. Multiply the quarter horse-power saved in one machine, supposing it to be stopped for fifteen minutes each hour, by, say, 50 machines running under the same average conditions, some requiring more and some less power, and you have a total of 12½ horse-power-hours saved each hour, or 125 horse-power-hours per day. Add this 12½ horse-power to the 18 horse-power, our average load, and we begin to approach the estimated load of our factory under former conditions of practice. To this we should add about 12 or 15 horse-power, which would be necessary to drive a line of heavy main belting through the six stories of this building, and we have a gross result of from 42 to 45 horse-power. We have wired up in the building a total of 220 lights—212 16 candle-power, four 20 candle-power, two of 32 candle-power, and two 100 candle-power. From 15 to 25 of these lights are used all day, about 150 to 175 more are used about three hours during the day. Whence comes this apparent something from nothing? I will try and explain to you. Every operator in our factory who has charge of a machine, be it a milling machine or drill press, a lathe or planer, has a certain and absolute direct and instantaneous control over the automatic valve gear on our engine in the basement through the medium of the belt-shifter on his machine. We will suppose he is using a milling machine. The piece being milled has finished its travel, and the machine is stopped by shifting the belt on to a loose pulley. A horse-power of duty has been taken off of the electric motor driving that machine, the tension on the motor belt relaxes to exactly that extent, the counter E.M.F. in the armature of the motor instantly increases, and the horse-power of current, which is no longer called for in the motor, the dynamo in the engine room ceases to generate, and the automatic valve gear on the engine immediately adjusts itself to a shorter cut-off."

As will be gathered from the foregoing, belting from floor to floor is entirely obviated, and in its place we find the wires running up from the basement from one floor to the other and connected directly with the motors. A conduit is built into the side wall, in which the conductors lie. The first floor, on which most of the armature parts are built and the winding is done, contains some 20 machines, and is operated by two motors, one of 1 horse-power, and another of 1½ horse-power. Here is also the testing room and draughting department, which contains a multitude of novel devices for the rapid testing of machines. On the next floor, on which the heavier machine work is done, some 30 machines are employed, among which are lathes, planers, drill presses, milling machines, and a large boring mill. This department is run by four motors connected to separate lines of shafting; two of these are of 3½ horse-power, and two of 1 horse-power. On first glance it seems almost incredible that machines of such small power should be capable of doing the work which is actually accomplished, but when we consider the fact that each machine individually is in operation for only a short time, even in the busiest times of work, the sum total of the power consumed at any one time is but a fraction of that required to drive all the machines simultaneously. Then, again, if it is borne in mind that the usual belting to shafting from floor to floor is done away with, it will be readily understood that the indicated load on the engine is claimed to be 50 per cent. less than would be required to operate the factory in the usual way.

The last of the seemingly endless Bell telephone infringement cases has just been decided. Judge Wallace, of the United States Circuit Court, in directing a decree for the American Bell Telephone Company in their suit against the Wallace Electric Telephone Company for infringement of patents, says that there is nothing distinguishable in essentials in that suit from those already decided by the Courts, nor was anything materially new disclosed. The Court considered that no useful purpose could be served by an extended discussion of the questions of law and fact which have been so exhaustively treated in the argument and brief of counsel for defendant, because nothing pertinent can be added to what has already been said in the previous opinion of the Courts. By this decision the construction which has been placed upon the Bell patent by the Courts is confirmed, and in all probability permanently established.

The course of trial trips with the Daft electric motor, "Benjamin Franklin," which has been proceeding daily since January 28th last, has resulted in the increased confidence of the public in electric traction and the unqualified satisfaction of the Daft Company. The tests were eminently successful. With eight empty cars in a train, making a load of 122 tons, a speed of 7½ miles an hour was obtained up a gradient of nearly two per cent., without the slightest noticeable strain upon the locomotive, although the development of energy exceeded 120 horse-power. With a four-car train, the standard for the Ninth Avenue line, carrying an average load of passengers, 15½ miles an hour were easily made up the same gradient, an excess of 2½ miles over the running time of the steam trains between stations. The "Franklin" has on several occasions attained a speed of 30 miles an hour, and it is probable that 35 miles an hour may be considered its ultimate speed. The absence of the thousand and one unforeseen emergencies that occur in the practical use of machinery of any kind, especially under such tentative conditions, has been very gratifying to those in charge of the motor. There has been no noticeable sparking or flashing at the brushes, either of conductor or commutator, which have for themselves shown a surprising and unexpected uniformity of contact and endurance. Under the heaviest work it has been subjected to no journal has ever heated, neither field nor armature has been perceptibly warmer, and everything indicates that in all respects the "Franklin" possesses a very large factor of safety.

The Association of Edison Illuminating Companies began its ninth annual session at Kansas City on the 12th inst. with a full attendance. An important Paper by Mr. Edison on incandescent lamps was read by Mr. J. H. Vail, the secretary of the Convention. The convention was a most successful one, all the delegates reporting an increase in earnings and most gratifying prospects for the coming year. The prevailing topic, of course, was the Bate decision, and it was naturally regarded as the presage of the complete overthrow of the opposing companies. The question of joining the National Electric Light Association was discussed, and eventually negatived.

Mr. Edison had a very pleasant surprise last Monday morning. It was his forty-second birthday, and as he entered the great library in the laboratory which the day before had contained a few serviceable but unpretentious tables, some odd chairs, a few well-worn rugs and a dismantled clock, a remarkable transformation burst on his vision. Carved oak tables, handsome leather-covered chairs, each bearing the monogram "T. A. E.;" a big gas log burning brightly upon a pair of fantastic wrought-iron andirons, and a new face on the old clock, which had been connected so as to be regulated by wire direct from Washington, were among the changes. But the gem of the whole was a phonograph in steel, gold and silver, provided with the new automatic regulator for adjusting the pressure of the stylus upon the wax cylinder. It is the first "complete" phonograph ever made. Mr. Edison had been at work on the new regulator for three months, and had completed it only the Saturday previous. Mr. Edison soon evinced his recovery from the somewhat startling surprise by sending for a caterer, and ordering luncheon to be served for the 130 persons in the laboratory.

CORRESPONDENCE.

AN EXPERIMENT IN THE THEORY OF ELECTROLYSIS BY PROF. W. OSTWALD, OF LEIPZIG.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Prof. Ramsay has been good enough to send to me, as a secretary of the Committee of the British Association on Electrolysis, the following translation of a letter he has received from Prof. Ostwald. He told me of the experiment described by Ostwald some time ago, and I expressed scepticism on purely experimental, not on theoretical grounds. Perhaps scepticism is too strong a word, but at any rate I thought the assertion wanted substantiating. It is related by Ostwald as a definite experiment, but it is related without any of the concomitant circumstances which aid one so much in forming a judgment. This is the experiment referred to by Prof. Ramsay in his preliminary remarks with which the accompanying communication begins.—Yours, &c., OLIVER J. LODGE.

17th February, 1889.

[ENCLOSURE.]

The following letter of Dr. W. Ostwald requires a short introduction. In the *Zeitschrift für Phys. Chemie*, 1888, p. 270, Ostwald adduces arguments in favour of the supposition that the conductivity of electrolytes is approximately proportional to the amount of dissociation which they display in solution. I shall not here adduce these arguments, but in the introduction he gives the following "proof" that a solution of potassium chloride, for example, contains free chlorine atoms and free potassium atoms. Two glass vessels, insulated, each contain a solution of potassium chloride. They are connected together by a siphon filled with a similar solution of potassium chloride. A negatively electrified rod is placed near one of the vessels, and while it is still there the siphon is removed. The vessel nearest the rod is now positively electrified; it has received a positive charge from its neighbour vessel, and this charge has carried with it positively electrified potassium atoms, while negatively electrified chlorine atoms remain in the other vessel. These atoms are *free* in the solution. When a conducting wire is now dipped into the solution, "the potassium atoms float up to it, part with their positive charges, and then act on the water, forming potash and evolving hydrogen, which, if the charge was great enough, appears in bubbles, but which, at all events, polarises the platinum wire." Such an experiment shows that it is easy to prepare a liquid containing excess of one or other ion, and to separate the ion at the surface of an electrode by removing the electric charge of the ion.

It is unnecessary to follow the further matter of the Paper here. The view of electrolysis struck me as an unusual one, and on writing to Prof. Lodge he confirmed my opinion. The following letter from Prof. Ostwald will now be understood; it further states his views on the mechanism of electrolysis:—

LETTER FROM PROF. OSTWALD TO DR. RAMSAY.

[*Translation.*]

As regards the theory of electrolysis and the experiments described in Heft 5 of the *Zeitschrift* of Physical Chemistry, I am astonished that such simple matters can be doubted. I regard electrolysis in the following manner, without thinking for a moment that I am stating a new theory. Let E (Fig. 1) be the

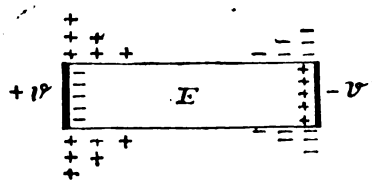

FIG 1.

electrolyte (*e.g.*, solution of potassium chloride); the electrodes are given the potential $+v$ and $-v$ in any convenient way; for example, by means of a battery. On the left side negative chlorine atoms are attracted; for I assume that a solution of potassium chloride contains many free ions of $\overset{+}{K}$ and $\overset{-}{Cl}$. The positive atoms of potassium move towards the surface, and produce the same electrostatic charge there as would be produced by the charging of a metallic conductor. Corresponding phenomena with reverse sign occur at the negative electrode. By this means an electrostatic impulse (*Triebkraft*) is given to the interior portion of the electrolyte, which urges the negative atoms towards the left, and the positive towards the right. If the potentials $+v$ and $-v$ are sufficient to force the ions to part with their electricity, they do so, and return to their usual state, and an electric current is the result; but if $+v$ or $-v$ is too small, the effect is a polarisation of the electrodes, caused by the ions adhering to them. The process of the conduction of electricity in an electrolyte is thus perfectly analogous to that in a metallic conductor, except that in the first case the electricity is in union with the ions (*an die Ionen gebunden ist*), and compels them to accompany it in its movement. Such an explanation is, of course, only possible if the existence in the electrolyte of free ions be assumed. If this be done the process, as you see, is easily grasped.

Similar conceptions explain the experiment in which a statical charge is given to a liquid. You once expressed doubt as to whether the separation of hydrogen by a statical charge could be rendered visible. I have lately made a few experiments which have shown me that it is easy. It is necessary to discharge by means of a thread of mercury of 0·01 to 0·03 millimetres diameter (as used, for example, in a Lippmann's electrometer) contained in a capillary tube, and in contact with dilute sulphuric acid. It is then possible to render visible 1 milligramme of hydrogen. To separate 1 milligramme of hydrogen requires 3×10^{11} electrostatic units; it is evident that the hydrogen from 30 units can be made visible; it forms a bubble of more than 0·01 millimetre diameter. Let me describe one of several experiments I have made in conjunction with Dr. Nernet. A (Fig. 2) is a balloon of two litres capacity, fitted with dilute sulphuric acid, and placed on an insulated stand; the balloon is covered

Digitized by Google

with tin-foil. It is connected by means of a capillary siphon with B, a vessel also containing weak sulphuric acid, into which the capillary electrode C dips; C is connected to earth. If a positive charge be given to the outer surface of A by help of an electrical machine, the negative (SO_4) ions are attracted, and adhere to the glass walls of the balloon. The positive electricity is repelled, and along with the positive H ions passes to B until it reaches the mercury. But there the electricity alone goes further, leaving the hydrogen behind unelectrified. We have already been successful in seeing the hydrogen produced by a charge of such potential as to give a spark 0·1 to 0·2 millimetres long.

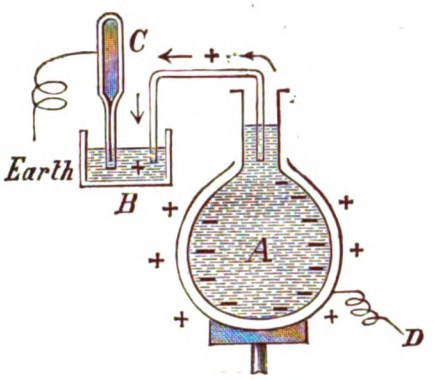

Fig. 2.

The movement of the ions under the influence of a statical charge is most easily seen in Lippmann's capillary electrometer. As you know, the indications of this instrument depend on the polarisation of the mercury meniscus. If the electrometer be connected with an insulated metallic ball the mercury meniscus makes considerable movements on the approach of an electrified body. This shows that the slightest motion of electricity in the electrolyte (here the dilute acid of the electrometer) cannot take place without a corresponding motion of the ions; it follows, as a necessary consequence, that the ions are free.

I hope that this communication, which will soon be published in full, will have removed your doubts. If you consider it desirable to send it to Prof. Lodge for publication you have my consent. I shall be glad to do anything to cause the spread of Arrhenius's happy theory.—Yours, &c., W. Ostwald.

Note by W. Ramsay.—The experiment originally recorded by Ostwald in the *Zeitschrift der Physikalischen Chemie* for April, 1888, was something like the one he describes in his letter, but lacked all precautions to render visible such a minute quantity of hydrogen as he appeared to have succeeded in seeing. I was in doubt as to the possibility of detecting such a minute charge, and also startled by Ostwald's confident assertion that the vessel B in his diagram, after A had received a charge and after the removal of the siphon, contained *free* potassium atoms, each laden with so strong a positive charge as to be unable to react on water until the charge had been removed by a wire to earth. Moreover, it appeared possible to represent the effect as one of ordinary electrolysis (whatever that may be), by supposing that the *surface* of the vessel B, and the *surface* of the contained liquid was charged positively, and that on making connection to earth a current ran from the surface *through the liquid* to the discharging wire, electrolysing the liquid during its passage. It occurs to me to ask those more conversant with the subject than I am what would happen if the vessel B were a metallic one on an insulated stand, and if it were discharged from its outer surface. The amount of current traversing the liquid would then be excessively minute. Would hydrogen be evolved? Also what would happen were the vessel B so strongly electrified that a spark could be taken from the surface of the liquid? In such a case, would the discharge not be wholly from the surface, and would the possibility of electrolysis (in the sense that electrolysis requires a current *through* the body electrolysed) not thereby be excluded?

I may add that I should not, on my own responsibility, have brought this question into prominence, although it appears to me to lie at the bottom of our conceptions of electrolysis, had I not been backed by the opinions of Profs. Fitzgerald, Carey Foster, and others, who thought it well to place it before the Electrolysis Committee for the purpose of eliciting an expression of opinion.

DISCHARGE OF A LEYDEN JAR.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Will you allow me to intimate to such of your readers as may happen to be present at the Royal Institution Friday evening, on the 8th March, that an opera glass will be serviceable for one or two of the experiments.—Yours, &c.,

Oliver J. Lodge.

21, Waverley-road, Liverpool, February 25, 1889.

HARROW LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: A report in the *Harrow Gazette* has found its way into the columns of one of the technical journals. Its form would lead a reader to suppose that it was absolutely verbatim, or, at any rate, sufficiently so to accurately represent what passed at the meeting. I find, however, on reading it over, that there are important omissions. For instance, after stating that I explained the two well-known methods of distributing electricity by alternating transformers and battery transformers, I am made to say simply that the former was the best suited for Harrow, whereas I took considerable pains to point out that although, as a rule, I had a preference for the battery transformer system, yet on account of the peculiar distribution of the Harrow lighting, in a small number of large houses distributed over a considerable area, the alternating-transformer system was at its very best as regards first cost when compared with the other; but I went on to say that if the other site which had been pointed out at the west end of the town was adopted, the balance would turn the other way.

I wish this to be clearly understood, as, since the reading of my Paper last year, and the discussion which followed thereon, there has been a disposition on the part of those who did not carefully follow that discussion to consider me as the uncompromising opposer of alternating transformers for any system of electrical distribution wherever it may be situated.

If those who are interested in the subject will turn to my Paper they will see that I then dealt with the unsuitability of the alternating-transformer system for central station lighting in densely-populated towns such as London: I acknowledged from the very first its great utility for lighting suburban districts, towns, or villages where the houses to be lighted are scattered over a considerable area, and where overhead conductors can be wholly or partially used.—Yours, &c., R. E. Crompton.

Arc Works, Chelmsford, February 26, 1889.

ELECTRIC BLEACHING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The *Paper Trade Review* in its last issue has published a letter entitled "Electrolytic Production of Hypochlorites," signed by Mr. Alexander Watt, in which it is stated that in my process for bleaching by electricity I claim the production of hypochlorite of sodium, which was patented by his brother, Charles Watt, in 1851.

Only three out of my eight specifications have been published by the Patent Office, and if Mr. Watt had waited a little longer he would have found in my first specification, which will soon be out, that I say plainly: "It must be understood that I do not claim at all the electrolysis of a chloride solution."

Now Mr. Watt, who speaks of his brother's invention, forgets, or seems to ignore, that his brother has simply copied and patented the method of electrolysis of chloride of potassium found by Gay-Lussac, Kolbe, Bouis, &c., known and experimented in France before 1851.

"En faisant passer un courant électrique à travers une solution de chlorure de potassium, M. Kolbe est parvenu à transformer le chlorure en chlorate de potasse et même en perchlorate.

Digitized by Google

Cette expériénce répétée avec des dissolutions plus ou moines concentrées, m'a constamment fournie de l'hypochlorite de potasse.

"Gay-Lussac dans son travail sur les hypochlorites a constaté que l'hypochlorite de potasse chauffé avec du chlorure de potassium transformer ce dernier en chlorate.

"Partant de ce principe que la température d'un électrolyte s'éleve sous l'action d'un fort courant, j'ai fait passer un fort courant dans une dissolution de chlorure de potassium, la température s'est élevée, la présence de l'hypochlorite s'est manifestée et j'ai pu reconnaitre le chlorate dans les produits qui s'étaient formés."

(See *Comptes Rendus de l'Académie des Sciences*, 1849, t. XXIX., page 403, "Recherches sur l'electrolysation," par Jules Bouis.)

What right has he to stand in the way of those who, like Mr. Hermite and myself, made an industrial application of an electrolytic method, which nobody up to the present was able to make efficient, practicable, and cheap? Has not Mr. Watt's brother had the time since 1851 to make something out of his patent? He could not bleach by electricity, and the proof is that he patented in 1854 a chemical process for bleaching fibres, which, like his electrolytical process, was stillborn.

My process in no way resembles Mr. Watt's brother's process. I have no diaphragm; my electrodes are not those his brother used; I do not heat my electrolyte at 120°F., &c.—Yours, &c.,

62, Loughborough Park, London, S.W., E. ANDREOLI.

ELECTRIC LIGHTING COMPANIES AT KENSINGTON AND WEST BROMPTON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As there is some misapprehension caused by an advertisement recently inserted in your paper as to the West Brompton Station of the House-to-House Electric Supply Company (Limited) (called by them the Kensington Station), I trust you will allow me on behalf of my company, the Kensington and Knightsbridge Electric Lighting Company (Limited), to furnish you with a statement of the works done by the respective companies in Kensington.

My company, the Kensington and Knightsbridge Electric Lighting Company (Limited), commenced in 1887 to supply electricity, under a License from the Board of Trade, in a limited area round the works situated at Kensington Court. The plant was furnished by Messrs. Crompton and Co. (Limited), who acted as the engineers and devised a system of underground mains, which gives complete satisfaction. Thereupon my Board decided to enlarge their operations, and apply for an extended area, a portion of which has since been granted. In consequence electricity is now supplied through several mains at a radius of three-quarters of a mile, and in a short time the distance will be considerably extended. There will, however, be no necessity in this district to carry the current more than two miles, as the company have a station in a central position at Knightsbridge which is now in course of completion.

From the mains already laid, shops, houses and public buildings (including the St. Mary Abbotts parish church) have been supplied with current night and day constantly with the utmost satisfaction.

As to the House-to-House Electric Supply Company (Limited), I am, after inquiring a fortnight since, in a position to state that in spite of all their protestations and advertisements, they have not to my knowledge supplied any current to houses or shops within the district of Kensington. Further, I am unable to see how they can claim to be the first company in London to supply an extended area through underground mains, inasmuch as they possess no License from the Board of Trade to break up the streets. I trust you will insert this in your next issue, as my company is suffering from the confusion which has arisen from the House-to-House Electric Supply Company (Limited) adopting the name of the Kensington station for their station at West Brompton, and making the claims above referred to.—Yours, &c., R. S. ERSKINE, Secretary.

Kensington High-street, London, Feb. 28, 1889.

THE KENSINGTON VESTRY REPORT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with great interest the leading article in your issue of the 8th inst., and desire on behalf of the Kensington and Knightsbridge Electric Lighting Company (Limited) to express their appreciation of the views expressed therein. At the same time it might be inferred that my company has been so neglectful of the interests of the industry as to act in the manner you have stated.

With regard to the unauthorised breaking up of the streets, my company have so far acted under Licenses from the Board of Trade, and as to the offers to accept a shorter period than 42 years, the term of the Provisional Order, I can only say that the proposition emanated from a rival company. I trust, Sir, that you will continue to warn the supply companies against any such stultifying action, and remain—Yours, &c.,

R. S. ERSKINE, Secretary.
The Kensington and Knightsbridge Electric Lighting Company (Limited).

COMPANIES' MEETINGS & REPORTS.

Telegraph Construction and Maintenance Company (Limited).

The twenty-fifth ordinary general meeting of the Shareholders was held at the offices of the Company, 38, Old Broad-street, on Tuesday, Mr. Philip Rawson in the chair.

Mr. WILLIAM SHUTER (Managing Director) read the notice convening the meeting and the minutes of the previous meetings, which were confirmed.

The CHAIRMAN said: I presume, gentlemen, you will take the report and accounts as read. Before commencing the proceedings, I wish to express, on behalf of our worthy Chairman, his extreme regret that he is unable to attend the meeting to-day. He is absolutely forbidden by his doctor to leave the house. He is suffering merely from a temporary ailment—a severe attack of bronchitis, I think—and that we shall soon have the benefit of his presence here again. In the meantime, he has always had a very pleasant business to perform on these annual occasions, because we have always had an account to present to you that I think must have given satisfaction. It now devolves upon me to move that the accounts and the report be accepted. In doing so I will just make a few observations, and I am very glad to think that very few observations are necessary. The report and figures are precisely in the same form which you have been accustomed to receive them. It is true that they do not enter very largely into detail; but, as you are aware, and as every business man must be aware, nobody chooses to expose the details of his business to the public, and in this instance it would be particularly undesirable that we should enter into detail. When the time comes, if it ever should come, that the meeting should demand a detailed explanation of every item, I think the time will then have arrived that you will have little confidence in your Board. Now, taking the text of the report first, you will see, without going through those figures, that we are still enabled to recommend a dividend of 20 per cent. for the year; and that during the past year the Factories at Greenwich and the Gutta-Percha Works have been very fairly employed. We have done a very considerable amount of work. A length of about 6,000 miles of telegraph wire has been insulated; that is including not only submarine wire, but wire for telegraphic purposes in this country. The company's steamers have laid cables in connection with the Dutch possessions, but I will enter into particulars of that presently. We have repaired the Brazilian submarine cable in January and August last year. We have also repaired the German Union cable once, and the Heligoland cable in March and November last year. The "Scotia" was also employed for three months in repairing the Direct United States cable. That was not a cable laid by ourselves; still, it was successfully repaired in two places and a considerable length added. A line was also laid of about 456 miles connecting the Dutch settlements of Java and Moluccas, and in August last the steamer "Macassar" left this country to connect Java with Western Australia by cable, a trifle under 1,000 miles in length, and I am glad to say we have this very morning had a telegram stating that that cable has been successfully laid, making now the third line to Australia. A little different route was chosen for that line, taking it if possible out of the district of the great volcanic disturbances of which we have heard so much of late years, and it is hoped that it will be well removed from the influence of those disturbances. A further contract, as no doubt most of you are aware, was entered into for completing and connecting the West African system with the Cape. The length of cable required for that was about 1,530 miles. The greater portion of it was manufactured this year, and a vessel will sail with it at the end of this week. That cable commences from a place called Mossamedes, a Portuguese settlement on the Western Coast of Africa, and will, when completed, be landed at Cape Town, thus completing the second line to the Cape. The fact is that Africa will then be surrounded by cable on all sides, east and west and on the Mediterranean coast. During the year, as the report already states, we have manufactured about 6,000 miles of insulated wire, including the cables and other wire for telegraphic purposes. That is about the account of our proceedings last year. The steamship

Digitized by Google

"Kangaroo," which was chartered by the Italian Government for distilling water in the Red Sea, has been returned, and has since been sold. No vessel we ever had, perhaps, has been more useful or added more to the profits than that old ship, which was called an "old tin pot" when we bought her. It has done very useful work. The steamship "Calabria" is now on charter on very good terms, and is running from Antwerp to the River Plate for emigration purposes. She is long between decks and is very well fitted for passenger purposes. The Company's works at Greenwich and Wharf-road are in excellent working order. The Directors, as you see in the report, regret very much the loss of their colleague, the late Lord Alfred Paget, who was on this Board and rendered very earnest assistance at all times to us for the space of 18 years. Fortunately we have been in a position to replace him by Mr. William Shuter, whom you all know, and whose appointment I am sure you will all approve. Mr. William Shuter, as you are all aware, has been connected with this Company from its very commencement, and has a very firm grasp of everything connected with the Company. He knows every detail from the very beginning, and his services will be most valuable. A sum of £150,000 of Six per Cent. Debentures has been renewed at 5 per cent., and they were all, with one small exception, taken by the original holders of them. Now, gentlemen, turning to the figures. As I said before, the figures are entirely in the form in which we have always presented them to you, and I do not think they require any observations from me. I will merely say that the debts owing to the Company are perfectly good, and the sundry securities which figure here for £468,641 represent securities which are perhaps a little more valuable than those figures would indicate. I believe we have no disputed account of any sort whatever. Every account we have open with our clients has been passed as correct, and the outcome of that is a balance of £82,580. 3s. 6d., which it is now for you to distribute. I will therefore move—

"*That the report and accounts of the Directors to the 31st December, 1888, submitted to this meeting, be and the same are hereby received and adopted; and that a dividend of 3½s. per share, in addition to the 12s. per share interest or interim dividend paid on June 30th, 1888, be paid on all the shares of the Company for the year ending December 31st, 1888, and that such dividend be paid free of income-tax.*"

Mr. GEORGE W. CAMPBELL: I have much pleasure in seconding that.

The CHAIRMAN: If there is anything I have passed over, or any information I can give, I shall be very glad to give it. (After a pause.) Then, gentlemen, if nobody wishes to make any observation I will put the resolution.

The resolution was carried unanimously.

The CHAIRMAN: The next resolution that I have to present to the meeting is—

"*That Mr. George William Campbell be and is hereby re-elected a Director of this Company.*"

Admiral SIR GEORGE H. RICHARDS, K.C.B., F.R.S.: I have great pleasure in seconding that resolution.

The resolution was carried.

The CHAIRMAN: The next resolution will come from the other side of the table, I think.

Mr. GIBSON: I have pleasure in proposing the following resolution:—

"*That Mr. John Gane, F.C.A., and Mr. James Gleyg, F.C.A., be and are hereby re-elected Auditors of the Company for the year 1889, at the same remuneration as last year.*"

We are satisfied with our auditors, and I have much pleasure in proposing this resolution, and trust that some shareholder will second it.

Mr. HEWAT: I shall have much pleasure in seconding it.

The motion was adopted.

The CHAIRMAN: That, gentlemen, is all the business before us.

Mr. HEWAT: I beg to propose a vote of thanks to the Chairman and Directors for their attendance now, and for their attention to our business throughout the year, which is always satisfactory to us, but I think I need not waste your time by saying what we all believe.

General TREVOR seconded the motion, and it was carried.

The CHAIRMAN: On behalf of myself and my colleagues I beg to thank you very much for your kind expression of opinion. We shall in future endeavour to act as we have done in the past, and to promote the prosperity of the Company to the best of our ability.

The meeting then closed.

Submarine Telegraph Company (Limited).

A meeting of the proprietors in this company was held on Tuesday at the offices of the company, 2, Throgmorton-avenue, London-wall, the Hon. H. R. Brand presiding.

The SECRETARY (Mr. S. M. Clare), read the notice convening the meeting, and the minutes of the previous meeting.

The report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, in moving the adoption of the report and accounts for the last half-year, I shall not detain you by any examination of them; I think that they speak for themselves. They show a progressive business, and the main consideration I think that affects us is one of regret that we have to part with such a good business. There is one other consideration of a more satisfactory character to which I may allude. You will observe that there is a large sum of money invested in various stocks, upon which, if we take their price at the present day, there is a profit of £28,000 to £30,000. Well, now I will give you in as few words as possible all the information in our possession respecting the arrangements with the Government for the transfer of the property of this company. It might have been supposed, and reasonably supposed, that long before this date the directors would have been in a position to give the full particulars to the proprietors; and indeed if this had been merely a question of the sale or purchase of a business between independent corporations or between private individuals, there would have been very little difficulty or delay in settling the matter. But you must expect delays when international arrangements have to be made. At any rate, I can say that the Board has not been responsible for the delay that has occurred, for they offered every facility in their power to the Government, and they have acquiesced in every suggestion that the Government has made, so long as they were able to do it without sacrificing the interests committed to their charge. There is one other consideration I would ask you to bear in mind, and that is the fact that throughout the whole of these negotiations the Board has not been in the position of a free agent. Their hands, so to speak, have been tied. So soon as the Governments concerned—the English, French and the Belgian Governments—had decided to take into their own hands and to work the telegraphic system between this country and the Continent, this Company lay under sentence of death. Not only would all its rights, its authority and power cease to exist, but also—and that is the main consideration—a considerable portion of its property would have no value unless it could be transferred to those who were about to conduct the same traffic heretofore carried on by the Company. That is a consideration which has always been in the minds of the Directors, and they have been consequently hampered by the knowledge that it was a necessity to transfer their property to the Governments concerned. Well, now, it was in March last year that the Company first received a definite proposal from Her Majesty's Government. A letter was addressed to the Company from the Treasury offering certain terms of purchase. Those terms were, generally, that the Government would take over the whole of the *employés* in the Company's service with the exception of seven, to whom they offered a small and, as I think, a somewhat inadequate compensation. They then proposed to take over the whole of the property of the Company—that is to say, the cables, ship, stores, and the house in which you are now sitting—in short, the whole of our property, with the exception of the two

cables known by the name of the Deolin and Salcombe cables. They proposed that this property should be taken over at valuation in the ordinary way—that is to say, that there should be valuers on behalf of the Government, as well as on behalf of the Company, appointed, and if there were any disagreement between them, reference should be made to arbitration. Well, gentlemen, the Directors did not consider that, in some respects, the terms offered by the Government were such as they considered adequate, but in the position in which they were placed they felt that they had no option but to accept the terms thus offered. But they urged the Government to re-consider their decision as to the Deolin and Salcombe cables, and I may say that, from personal assurances which I have received at certain interviews I have had with the Financial Secretary on behalf of the Board in the Chairman's absence, I feel confident that the Government will relieve the Company of the whole difficulty with regard to these two cables. This offer of the Government was made subject to conditions, and those conditions were that the assent of the other Governments concerned should be obtained in so far as the interests of those Governments were concerned. Well, thus matters stood until a very recent date, and at a recent date we received the following information from Her Majesty's Government, namely, that they were under a Convention with the French Government either to purchase cables or to lay down cables jointly, and that the French Government and the Belgian Government had not seen their way to accept the principle of arbitration. Under these circumstances the question was, what was the course the Company should take? I would refer you again to the remarks I have made as to the position in which the Company was placed, and it was obvious that although we considered that it would have been much more to the interests of the Company that the French Government should have accepted arbitration, yet under the circumstances we were compelled to accept the position and the alternative proposals made by the French Government. That Government having refused arbitration, proposed an alternative course of action. They proposed that there should be a valuation of the cables made. I may remark here that these difficulties have reference only to the cables, not to the other property of the Company. They proposed that there should be an independent valuation of the cables belonging to the Company by the officials of the French and Belgian Governments and by the officials of the English Government, and that they should have access to the books of the Company. Having examined the books of the Company and tested the cables, they could offer the Company a price for the cables which the Company could take or leave. Now, gentlemen, the Board certainly consider that that course is a somewhat arbitrary one, and one which might lead to most inequitable results, but they feel that they had no option but to accept the proposal. It is very difficult to estimate what will be the result of this valuation, but we have received the most positive assurance from the English Government and from the French Government that they wish to deal with the Company in a spirit of equity. And for my own part I am inclined to place some confidence in this assurance, because it is impossible to believe that these great and powerful Governments should wish to take the property of this Company in any other spirit than that of equity to those who are not only shareholders in this Company, but who are citizens of either England or France, and who may well look to their respective Governments to protect their interests. That, so far, is the whole state of the case at the present moment. I have nothing to add to what I have said, except to express a hope that their arrangements will be completed and the whole thing settled by the 31st of March. If and as soon as they are completed you will be called together again to sanction them. At that time Sir Julian Goldsmid, who is now absent on business on the Continent, will attend personally. Having given all the information which I have at present in my possession, I now beg to move the adoption of the report and accounts.

The Hon. ASHLEY PONSONBY seconded the motion.

Mr. SODEN said it was a high-handed proceeding on the part of the British Government arbitrarily to revoke the Company's license and confiscate their property. If their property was to be taken from them without fair compensation the same sort of pressure might be brought to bear on other companies with far better reason than applied in the case of the Submarine Company. He would, therefore, like to ask whether any steps had been taken by the Board since last year to interest shareholders in other companies similar to the Submarine, with the view of getting their united action to protect their interests. He thought the Company had a very strong claim equitably against the Government for damages in consequence of its action in preventing the Company from getting a renewal of its concession from the French Government.

Mr. ROSTRON asked whether the negotiations had been carried on by the Board or a sub-committee of the Board?

The CHAIRMAN replied that the nogotiations were carried on between the members of the Board, the Chancellor of the Exchequer, and the Financial Secretary to the Treasury. They were not in a position to contest with the French or English Governments. It would be an act of suicidal folly if they were to take up an attitude of antagonism to the Government, and to say that they would refuse the proffered terms. It was not a revocation of the license, but the expiration of their concession that had taken place. They ceased to exist on the 31st March, and what the Government said was, "We are willing to pay you fair value for your property. You have had it all these years with great profits, and now you come to the end of your life, and we are willing to give you fair value for your property. If you do not choose to accept it you must risk getting nothing for it." The Directors felt that they would not have been acting in the interests of the shareholders of the Company if they had not taken care to give no excuse for the Government not buying the system of the Company, and thus obviating the possibility of the Government laying down cables for itself; and the shareholders might rest assured that the Board had left no stone unturned to get the best possible terms for the Company.

The motion was then put to the meeting and carried unanimously.

The CHAIRMAN next moved the declaration of a dividend at the rate of 16 per cent. per annum less income tax, payable on and after the 1st of March next.

The Hon. J. S. GATHORNE HARDY, M.P., seconded the resolution, which was unanimously agreed to.

On the motion of Mr SODEN, seconded by a SHAREHOLDER, a cordial vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN briefly acknowledged the compliment, and the proceedings terminated.

CITY NOTES, &c.

ARTHUR B. GILL AND CO.—Messrs. Gill and Co. write to us as follows:—"Sir,—You are doubtless aware of the sale of the Sun Electric Light Company, who occupy the adjoining premises to ours, viz., 5, Bombay-street, ours being No. 4. Bombay-street being an uncommon name and a short street, many people in the City and elsewhere are under the impression that we are in liquidation. You will at once see what a serious result this may have on any tenders we are in for or other work. We have already received many letters asking what has happened. As a matter of fact, we are exceedingly busy, orders for dynamos, switches, motors, &c., coming in rapidly. We are engaged on several large installations, one alone at Westminster being for 1,400 lights. May we ask you to insert a notice in your next issue to this effect, for which we shall be much indebted to you?—Yours truly, ARTHUR B. GILL AND CO."

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended February 22nd, 1889, amounted to £5,927.

LANCASHIRE AND CHESHIRE TELEPHONIC EXCHANGE COMPANY.—An interim dividend at the rate of 7 per cent. per annum has been declared by this company for the half year ended December last.

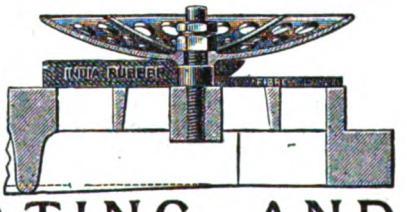
WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended February 22nd, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,884.

REMOVAL.—The Endolithic Ivory Company have removed from 24, Well-street, Jewin-street, to Pomona Buildings, Fore-street, E.C., adjoining Moorgate-street Station.

PERSONAL.—Mr. W. C. Mountain, having resigned the management of the Gülcher Electric Light and Power Company, informs us that he has joined Messrs. Ernest Scott and Co., of Newcastle-on-Tyne, where he has taken the direction of the electrical department.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 564.—Vol. XXII. FRIDAY, MARCH 8, 1889. Price Fourpence.

NOTES.

On Monday last the Court of Appeal delivered judgment in the case of Gaulard-Gibbs *versus* Ferranti, confirming the decision of the Court below, whereby the Gaulard-Gibbs patent of 1883 was declared invalid. Matters have now, however, taken a new turn by the announcement of the recognition by the leading makers of the priority of the Jablochkoff patent of 1877. Further particulars of this will be found in a subsequent article.

Those of our readers who have the *entrée* of the Royal Institution will scarcely need to be reminded of the lecture by Dr. Oliver Lodge this (Friday) evening "On the Discharge of a Leyden Jar." Dr. Lodge intends first to run over the history of our knowledge of this subject, from the early researches of Franklin, and the long-neglected experiments of Henry (recently explained in these pages by Dr. Fleming), to the mathematical investigations of Thomson. Stress will be laid upon the generality of the problem, and Dr. Lodge will point out that *all* cases of charge and discharge are essentially of the order of the Leyden jar. The conditions of the problem will be illustrated by mechanical analogy, showing on what the rate of oscillation depends and how it can be calculated; and it will thus be made to appear that oscillations in the discharge are a necessity unless they are damped out by high resistance. The oscillations being, moreover, regular or periodic, inevitably give rise to the phenomenon of electric resonance, in strict accordance with the analogy of sound waves. Electrical analogues of the well-known experiment of causing the vibrations of one tuning fork to set another in vibration, and also of a tuning fork exciting a stretched string of suitable length, which in turn reacts upon the fork, will be described. The knowledge thus afforded by theory will be applied to the problem of reducing the speed of the electric oscillations, bringing them down gradually from some millions a second to only a few thousands, and ultimately to a few hundreds per second. As the period increases in length the noise made by the spark undergoes a striking change; from a mere crack it becomes first a shrill whistle, and ultimately a musical note whose pitch is easily ascertained. The oscillatory character of the spark will be further demonstrated by analysing it in a revolving mirror, and Dr. Lodge hopes to render the serrations of the band of light distinctly visible to every one in the theatre. Finally, the instantaneous rotation of the plane of polarisation of light will be effected by means of a Leyden jar discharge, taken round a block of "heavy" glass or a tube containing bisulphide of carbon. It will be shown that the momentary restoration of light as the current passes is oscillatory in character, and by means of the rotating mirror it will be seen that the oscillations are in unison with the spark. The image of the light which has come through the tube splits up into a broken band of light, and the bright lines are seen alternately to wax and wane when the Nicol prism analyser is rotated in either direction.

To-morrow (Saturday) afternoon Dr. Lodge will repeat some of these experiments, with others in addition, before the Physical Society, when he will, no doubt, go somewhat more deeply into theory. A new and highly-interesting experiment will be that of the production of an electro-statie field by means of varying magnetic induction. This experiment is, in some sense, the converse of that shown by Dr. Silvanus Thompson before the Royal Society last week, but it is perhaps still more completely the converse of Prof. Rowland's experiment, in which a magnetic field is produced by the rotation of an electrostatic charge. The final importance of the experiment will be greater or less according as it has or has not a bearing upon high electrical theory. On this point we believe that Dr. Lodge has not yet arrived at any very definite conclusion. It may, however, at least, be said that Maxwell's theory rendered the existence of such an effect extremely probable. We shall hope to hear the opinion of Prof. J. J. Thompson on this point. Dr. Lodge will then repeat some of the most important of the Hertz experiments, with various modifications and extensions of his own devising. It will perhaps be remembered that Hertz (see *Electrician*, Nov. 16th, 1888, p. 44) came to the conclusion that the actual velocity of electrical pulses along a pair of isolated wires was not in conformity with Maxwell's theory. We believe that Dr. Lodge will show, on the contrary, that the velocity is sensibly equal to that of light.

Prof. S. P. Thompson's Paper "On the Magnetic Action of Displacement Currents in a Dielectric," read before the Royal Society last week, was of the highest interest. According to Maxwell's well-known views of electrostatic action, the variations of electric displacement which occur during the charge or discharge of a dielectric are to be regarded as equivalent to electric currents. No direct experimental proof of this point had hitherto been forthcoming. Prof. Thompson having calculated out, on the assumption of the equivalence between displacement-currents and conduction-currents, what the effect

Digitized by Google

would be of the charge or discharge of a condenser upon an astatic needle placed near the edge of the condenser, concluded that the effects would be too delicate to be measurable. He therefore resorted to a different method based upon the principle that, if a closed curve be drawn around the flux of electrostatic displacement, the line-integral of the magnetising force, reckoned once round this closed curve, will at any instant be a measure of the rate of change in the electric displacement through the curve. An iron annulus surrounded by a coil of fine silk-covered copper wire is embedded in a layer of paraffin wax between two glass plates, and pieces of tinfoil are affixed on the outside surfaces of the plates to serve as the coatings of a condenser. The electric displacement passes through the aperture of the iron annulus. Any changes in that displacement set up magnetic forces acting round the iron annulus, which thereby is subjected to a varying magnetisation. The annulus in turn sets up induction currents in the copper wire that surrounds it, these induction currents being received and rendered audible in an ordinary telephone receiver. The condenser is connected to a Ruhmkorff coil, which rapidly charges and discharges it. The sounds heard in the telephone receiver are taken to establish the reality of the magnetic action of the variations in the electric displacement. The author points out that this device, which may be regarded as a new kind of proof plane for exploring varying electrostatic fields, is probably capable of other useful applications, such as the investigation of specific inductive capacities. It will, however, be evident that the results require to be interpreted with the utmost care to avoid the interference of extraneous actions. But in any case the immense ingenuity of the experiment will be patent to all, and Prof. THOMPSON's further communications upon the subject will be looked forward to with great interest.

THE important Paper of Prof. FORBES on "Some Electric Lighting Central Stations in Europe and their Lessons," read before the Institution of Electrical Engineers on February 28th, was divided into distinct portions; the first part included a detailed description of the central stations of Berlin, Milan, and Rome, and the second part was more particularly devoted to the lessons which English engineers may derive from a study of the Continental stations. The second part of the Paper being quite complete in itself, we print it first in order to give proper time for the preparation of illustrations for the former part. Meanwhile we commend Prof. FORBES's "Lessons" to the careful consideration of every engineer engaged in central station work.

THERE is much in this Paper of Prof. FORBES upon which we should like to comment, but in the present issue space will not permit us to do more than refer to a single point. We observe that Prof. FORBES lays stress upon the calculation of mains and feeders in accordance with the law of THOMSON. We venture, however, to doubt whether the formula in question really admits of practical or useful application except in the case of constant-current circuits. It is not the truth of the law itself that we call in question, but the possibility of discovering the data to which it is to be applied. It is true that Prof. FORBES himself has greatly facilitated its application by means of the valuable tables which are given in his "Cantor Lectures" of 1885. But not only is the question grievously complicated by the fact, insisted on by Mr. CROMPTON, that the cost of copper bears a smaller ratio to the total cost of laying mains than was at first supposed, but still more fatal is the difficulty of ascertaining what is the value of the square root of the mean square of the current taken over a whole year. Even for a station already in operation the determination of this quantity would be sufficiently troublesome, but to do so on paper before the station is constructed would be simply impossible. In practice we know that it is customary to calculate out the mains on the basis of the permissible fall of potential under full load at the extremity of the circuit, and since we thus obtain the minimum permissible value, it seems doubtful whether it is worth while to hazard a further capital expenditure upon the result of a hypothetical application of the law in question. We do not suppose that Sir WILLIAM THOMSON would himself recommend the use of the formula where the data are so little ascertainable.

AT the Society of Arts on Wednesday evening Prof. S. P. THOMPSON delivered a most interesting and practical address on Arc Lamps. When Prof. THOMPSON undertakes to deal with a question of this kind we have learnt to expect from him a systematic exposition alike of the history, the practice, and the theory of his subject; it is therefore sufficient to say that Prof. THOMPSON on Arc Lamps exhibited the same qualities which characterise his now classical Papers on Mercury Pumps, on Influence Machines, on the Reiss Telephone, and on Dynamo Electrical Machinery. Next week we hope to reprint the address from the *Journal* of the Society of Arts, but it is much to be wished that he could be induced to expand the lecture into the form of a treatise.

THE renewed attempt to introduce into the telegraphic world a Morse code with its dots and dashes perpendicular to the paper instead of horizontal will be noticed with interest by those of our readers who remember Mr. HERRING's energetic endeavours to impress this system on Mr. SCUDAMORE nearly twenty years ago. Messrs. SIEMENS' ingenious method, which we describe and illustrate in another column, differs materially from Mr. HERRING's; but the object is the same; and in addition to the difficulties he had to encounter at that time there is now an additional one in the general adoption of Morse "sounders" to the exclusion of ink-writers altogether, except for fast speed working. If Messrs. SIEMENS' mechanical device can be trusted for Wheatstone "receivers," something possibly may be said for its adoption; but we are not prepared to endorse the opinion that the operators would prefer this kind of "printing." Mr. HERRING said the same thing, but we rather fancy nobody else did.

ALTHOUGH opinions differ as to the possibility of the Copper Syndicate tiding over without absolute disaster the crisis now impending, there is a general agreement that prices will

Digitized by Google

shortly go down, sellers for delivery of copper at three months accepting terms far below present quotations. The steady refusal to buy at an abnormal figure has at length brought the Société to its senses, if not yet exactly to its knees, the total deliveries during the past twelve months amounting only to 59,052 tons, while the supplies, it is said, have exceeded 124,000 tons.

SOME reassuring statements were given in Parliament by the POSTMASTER-GENERAL on Monday last with regard to the acquisition of the Anglo-French and Belgian cables. Little doubt now remains that the whole of the lines connecting this country with the Continent will be working under the control of the several Governments at the beginning of next month. More than this, there is good reason to believe that reasonable counsels have at length prevailed with the French Government in respect to the cables and plant of the Submarine Telegraph Company, and that their property will be purchased, if not at what the company consider a fair price, at a valuation something substantially above that of old stores.

SOME few weeks ago a paragraph appeared in the *Financial News* to the effect that electric traction was only to be used upon one portion of the City and Southwark Subway, and that cable haulage would be employed between the Monument and the Elephant and Castle. This information was so much at variance with facts within our own knowledge that we passed it by without remark. On Wednesday, however, our contemporary repeated the statement in categorical form, and descanted upon the folly of the proceeding in no measured terms, as may be seen from the following extract:—

"No sane body of men would dream of increasing the capital expenditure of such an undertaking by installing two different systems of haulage in a subway about four miles long. The change of the power used is almost as silly as a break of gauge would be. Every vice of mismanagement is embodied in this mischievous policy, and the directors owe not only an explanation to the shareholders, but also their resignation."

Although this language is a little rougher than that which we are ourselves accustomed to employ, yet it would be scarcely too strong if the facts were precisely as our contemporary supposes them to be. We have reason, however, to believe that the case is not quite so bad as this. It seems to be true enough that a cable plant is to be put in, but this will not be allowed to interfere with the contract with Messrs. MATHER and PLATT, which involves the actual working of the whole line by electricity. The cable is, in fact, to be put in as a stand-by. But we are entirely of opinion that this will prove to be a wholly superfluous precaution.

WHILE reading lately an interesting work on electricity, written a hundred years ago by one GEORGE ADAMS, "Instrument maker to His Majesty," entitled "An Essay on Electricity, explaining the Principles of that Useful Science, and describing the Instruments contrived either to Illustrate the Theory or to render the Practice Entertaining," our attention was arrested at an early stage by frequent allusions to Directors, and in particular to the "bottle director." Since those days electricity has suffered much at the hands of directors, but the bottle director is now, we believe, an extinct variety. Judging, however, from the rigorous treatment herein prescribed for him he must have been a fearsome creature when in his prime. One means of dealing with him is as follows:—"Connect a director by means of a wire with the ball of a Leyden jar, charge the jar, and then apply the point of the conductor." We then learn that "if a wire is conveyed from the bottom of this to the top of another director, the bottle director will be discharged." It would be a fine thing for the profession if directors were as easily discharged nowadays.

Burton-on-Trent.—The National Telephone Company's new exchange at Burton was formally opened last week by the Mayor.

St. Olave's Board of Works.—At a special meeting of this Board last week it was decided to take no action with regard to the electric lighting of the district.

Melbourne Exhibition.—Messrs. Gent and Co., of Leicester, have received a first-class award at the Melbourne Exhibition for their exhibit of electrical apparatus.

The Thomson Electric Welding Company.—This company has issued a neatly got up pamphlet describing the Thomson process, and enumerating its many advantages.

"Western Electrician."—Our enterprising contemporary the *Western Electrician* brought out a daily edition during the recent meeting of the National Electric Light Association at Chicago.

Accident to Mr. Edison.—We regret to learn that Mr. T. A. Edison has been badly injured in the eyes by chemicals during an experiment. By a later telegram it is stated that no permanent injury is likely to arise.

An Insulation Knife.—The *Elektrotechnischer Anzeiger* of Berlin calls upon makers of tools to bring out a special instrument for stripping insulation off wires, to replace the present rough and ready method of scraping with a knife.

Lisbon-Oporto Telephone.—A new telephone line has recently been completed between these two towns, and will be shortly opened to the public. The charge for five minutes' conversation will probably be fixed at 200 reis (about 11d.).

Electric Wire Casings.—Mr. Samuel Elliott, of Newbury, has just issued a new illustrated catalogue of his well-known electric wire casings. Drawings of over one hundred varieties of casing are given, many of which are of very tasteful design.

Sale of Postal Telegraph Stores.—Messrs. Horncastle and Pember announce the annual sale of postal telegraph stores, by order of the Postmaster-General, on Wednesday, March 13th, at the Commercial Sale Rooms, Mincing-lane, London, E.C.

Telegraphic Money Orders.—In reply to a question by Mr. Henniker Heaton on Wednesday evening Mr. Raikes said he hoped soon to be able to announce the date when telegraphic money orders would be introduced by way of experiment.

Gas and Electricity.—It is stated "upon the authority of a Parliamentary return" that the total capital now invested in gas lighting in this country amounts to £74,289,595, of which sum no less than £7,216,897 has been invested within the last seven years.

Engineers' Society of Western Pennsylvania.—The secretary of this society writes us to the effect that the library rooms are open daily, and engineers from any part of the country are invited to call and make themselves known to the secretary, Col. S. M. Wickersham.

Proposed Electric Railway in India.—The *Indian Engineer* says that Colonel Thomason, R.E., is busy surveying the country between Naini Tal and the plains, at his own cost, with a view to the construction of an electric railway, for which he considers the available water-power furnished by the lake, now running to waste, sufficient and to spare.

Digitized by Google

Milan.—A paragraph appeared last week in our contemporary *La Lumière Electrique* to the effect that a serious breakdown had occurred in the lighting of Milan. We have, however, received a letter from a correspondent on the spot, who states that this rumour is absolutely without foundation, and that the entire plant is continuing to work with perfect success.

Okehampton.—The directors of the Okehampton Gas Company have decided to apply to the Town Council for permission to lay cables in the various streets in the town for the purpose of supplying the electric light. The directors have thought this step advisable in consequence of the successful installation of the electric light in the town by a local firm (Messrs. Geen and Co.).

The Lighting of Mexico City.—Mail advices just to hand, dated Mexico, February 15, state that the city is at present illuminated by 300 arc electric lights of a combined lighting power of 600,000 candles; 114 turpentine and naphtha lights, of an illuminating power of 11,140 candles; 123 oil lamps, of an illuminating power of 783 candles; and 501 gas lamps, of a lighting power of 4,008 candles. The monthly cost of maintaining these lights is stated to be $13,449.

St. George's (Hanover-square) Vestry.—At a meeting of this Vestry last week the Electric Lighting Committee submitted a report recommending the Vestry to refuse altogether the application for a Provisional Order made on behalf of the Chelsea Electric Supply Company. The committee had adjourned the consideration of applications by the London Electric Supply Corporation, the Metropolitan Electric Supply Company, and the Westminster Electric Supply Company, all of which would be reported upon at a future meeting.

Lighting Buoys by Electricity.—The South Wales *Daily News* suggests that the unilluminated buoy off Lavernock Point should be lighted by electricity like the buoys in Gedney's Channel, New York Harbour. "On a clear day," this journal remarks, "there is absolutely no necessity for it, and at night and in thick weather it cannot be seen. Moreover, it is a source of danger, as considerable care has to be exercised to prevent coming into collision with it. If it is to be kept in its present position and turned to some account, there is no question that it should bear a light."

Telegraphs in Mexico.—Mexican advices state that the telegraphic system of Mexico is being rapidly extended throughout the country, and now all the cities and large towns and nearly all the important villages are in direct telegraphic communication with the capital. One of the leading papers says that the ordinary rates over the Government wires are quite moderate, and doubtless do much to encourage the people to make liberal use of the telegraph. It is argued, however, that the rate for press messages is too dear, and a reduction is asked for from 1 cent. per word, the present rate, to ¼ of a cent. per word.

Bremen.—The Electric Lighting Committee of the Bremen Municipality has decided by six votes to one to recommend the Council to refuse the offer of Messrs. Siemens and Halske to undertake the lighting of the town. The committee point out in their report that the result of such a contract would be a high tariff; on the other hand, the towns which have undertaken the work themselves have already been able to materially reduce their original charges. Messrs. Siemens and Halske at present fix the expenses of working 12,000 lamps at 2·46 centimes per lamp hour, and 22,000 lamps at 1·85 centime per lamp hour.

Copper.—The *Daily News* says:—"The deliveries of copper in England and France last month were only 1,397 tons, being the lowest remembered, and barely a fifth of the average monthly deliveries of the past three years. Of late consumers have been holding off the market with the greatest determination, prices for delivery three months ahead having been much below the spot quotations. What the French syndicate are gaining by upholding these prices it is difficult to see. Meanwhile the visible supply is 118,140 tons, an increase of 8,612 tons for the month and of 65,547 tons for the past twelve months. If the price were reduced to £65, and kept steady, they might—with aid on this side—escape disaster yet."

Submarine Mining.—Major Grant Ogilvie recently delivered a lecture to the members of the East of Scotland Tactical Society on "Submarine Mining." Major Ogilvie pointed out that the old mechanical mines were as much in the way of friend as of foe, and were difficult to remove after hostile operations were over. Among the many possibilities which an electrical arrangement introduced he enumerated a few. These were (1) the mines might be laid out and remain quite harmless so long as the firing current was not put on; (2) the mine might at any time be fired from the shore; (3) the mine might be fitted with a firing apparatus, so that the bumping of the mine by a vessel would complete the circuit and fire the mine; (4) the arrangement of the firing apparatus might be altered so that bumping would merely indicate on shore that a certain mine had been struck, and thus leave it to the discretion of the officer in charge whether the mine should be fired or not. In conclusion, Major Ogilvie remarked that the utility of mines as a means of defence must not be measured merely by the actual damage they inflicted, but their moral effect must be taken into account as well.

Taff Vale Railway and the Electric Light.—As we mentioned in our issue of December 14th, the Taff Vale Railway Company have decided to light two trains on the Penarth section by electricity. This is intended as an experiment only, but should it turn out successfully the whole of the trains on the system will be similarly lighted. Some details of the method to be employed are now to hand, and it will be seen that it is substantially the same as that which has been worked so successfully on the Brighton and South Coast Railway. The dynamo, which is a Brush machine specially wound so as to maintain a constant difference of potential at the terminals while the speed varies between certain limits, is run off the axle of the guard's van. The lamps (12 candle-power Edison-Swan) are run direct off the machine whenever the train is going at its normal speed, but when the speed is reduced the lamps are automatically switched on to a battery of accumulators. During the time the train is running the dynamo is charging the accumulators as well as furnishing current to the lamps. The cables are run along the roofs of the carriages, being connected at the end of each by means of a special coupling.

Gas Mains as Electrical Conduits.—Mr. P. H. Wilkinson, of Harrogate, writes to the *Journal of Gas Lighting*, as follows:—"I notice that, in an extract from the *Electrical World*, a claim for having in 'the first instance' applied telephonic wire in gas-mains is attributed to New York for work done about four years ago. Upwards of five years since—viz., in August, 1883—I laid down a number of 16 B.W.G. copper wire, gutta-percha coated to No. 4, and protected with prepared tape covering, in a live gas-main upwards of a mile long from the office to the works, with branches therefrom to my residence. The wire was laid on the bottom of the gas-main without any further insulation. I have testing-boxes, easily accessible, every 250 yards, and any portion can be taken out or renewed if required. . . About 400 yards of a 2in. main carries two wires, and three or four main valves are passed *en route*. The insulation appears as good as when it was put down, and no repairs whatsoever have been required. The gas mains carrying the wire run for about 500 yards within two or three feet of a main line of underground telegraphic wires, some of which have been renewed at least once during this period. A previous wire of similar description, carefully laid in pitched wooden troughs and in good soil, was continually under repair, and was frequently unavailable when particularly required; and in a few years it was left in the ground as useless."

The Thomson-Houston Electric Railway System.—The Thomson-Houston Electric Company have recently issued a well illustrated and readable pamphlet of some 30 or 40 pages, describing the various lines at present in operation under their patents, and announcing that they have purchased all the patents, privileges and licenses of the Van Depoele Company, of Chicago. The greater portion of the pamphlet is taken up by testimonials from users of the Van Depoele and Thomson-

Digitized by Google

Houston systems. Some few pages at the end are devoted to combating possible objections to an overhead wire system of electric traction, and to demonstrating the unsatisfactory nature of the battery system. "There are now in the United States alone more than thirty electric railways operated entirely by the direct method; there is not a single railway operated entirely by storage batteries. Experimental storage battery cars are, however, run from time to time on various roads, and many railway officials are induced to ignore the practical success of the direct system, and to wait the development of an ideal system, which so far refuses to be developed." We notice on page 39 that the trolley making a flexible upward contact, which forms so marked a feature of the Sprague line at Richmond, is said to be covered by a patent granted to Mr. Van Depoele.

Greenwich Board of Works.—The Greenwich District Board of Works met specially on Wednesday last week to consider an application made by the London Electric Supply Corporation for a Provisional Order for the supply of electricity in the district. The Clerk thought that the company would not be prejudiced by delay, and in his opinion it was necessary that the committee should have the services of an electrician. He suggested that a meeting should be held a fortnight hence, and that an electrician should be consulted. The Clerk's advice was adopted. The Clerk then reported that the Electric Light Supply Corporation had excavated roads in Deptford, and commenced to lay down mains, but he had stopped them, as they were blocking the thoroughfares. The Corporation ought to have done the work at night and in the way prescribed by the Board's officers, but instead of so doing they had put the matter in the hands of two gentlemen who seemed to have had no experience whatever in digging trenches and laying pipes. They employed 100 men out of the streets, and the work was done in a most unworkmanlike manner. The Manager and Secretary of the Corporation had expressed their regret that any irregularity had been committed, and had given orders for nothing further to be done at present. It was obvious that in putting down these pipes the Corporation were attempting to steal a march on the public and to get as many of their mains laid as possible. It was then agreed that the Clerk should give notice to the Corporation to undo all they had done.

Nottingham.—At the meeting of the Nottingham Town Council last week the following letter was read from Messrs. Maples and McCraith:—"Dear Sir: We are instructed by the Nottingham Electric Light and Power Company (Limited), a company which has just been formed with a registered capital of £100,000, to ask for the consent of the Town Council to the putting down of underground wires in the town of Nottingham for the purpose of the supply of electric light and power. The area proposed, speaking generally, is the Nottingham Park and the lace market, with some streets adjoining thereto. What is suggested is that the main streets should be taken in that area, such streets to be settled between the company and the Corporation. The company will be prepared to incur a very considerable expenditure at once, and are desirous of proceeding with the matter as quickly as possible; for this reason, therefore, we propose that the Corporation should proceed as has been done by the Metropolitan district, by the Vestries (acting under the advice of their Parliamentary agents), namely, enter into an agreement with the company to in 'so far as the Corporation powers extend, give to the new company the privileges and concessions which a Provisional Order would give when obtained.' The company would then proceed with the works (thereby supplying employment to a considerable number of persons in the town), give notice of the Provisional Order, and in all probability obtain same by the middle of next year. The company would be quite willing to insert in the agreement with the Corporation the same regulations as to public safety and other points which would be inserted by the Board of Trade in the Provisional Order. As the company understand that the lighting of the Castle Museum with the electric light would for many reasons be considered a public benefit they would be prepared to undertake this on very favourable terms. Our clients, the company, as they are asking for a concession of a particular area, will be prepared to submit to compulsory powers in that area. As to the streets, of course, this is a matter which will have to be arranged entirely subject to the Corporation views, although we may say that the street disturbance in laying down wires is extremely slight. The company will throughout the matter be desirous of acting in thorough unison with the Town Council and its advisers.—We are, dear sir, yours faithfully, MAPLES and McCRAITH." The Mayor said the application made by the Electric Light Company was of so important a character that he thought it advisable to move for the appointment of a special electric lighting committee to consider the matter. This was agreed to, and a committee was appointed accordingly.

Cheltenham.—The following is an abstract of the report of the Electric Lighting Committee of the Cheltenham Town Council, which will be considered at a meeting of the Town Council on Monday next. In reporting the committee first called attention to the position in which the question of electric lighting in Cheltenham at presents stands. Several interim reports have already been sent in by the committee to the effect that it was desirable to try the experiment of lighting a portion of the town with the electric light, and further, that it was desirable that the lighting of the streets should be carried out by the Corporation. These resolutions were accepted unanimously by the Town Council, who directed the committee to inquire into the question of cost. The report then goes on to say, that "With a view to make their estimate of cost, though approximate only, one that may be relied on as sufficient, the committee have placed themselves in communication with two of the largest electric lighting companies in the world, and have obtained from them covering estimates, that is to say, estimates within which they would themselves contract to do the work. From the inquiries made by the committee and information supplied to them, they have been strengthened in the conclusion they had come to that the cost of the public lighting would be very materially reduced by combining it with the supply of the light to private consumers, as it is well known that the electric light can be produced at a proportionately lower cost when the size of the installation is increased, and they have, therefore, included in their estimate provision for such combined supply. The committee have invited estimates on the basis of the supply of 60 1,200 candle-power arc lamps, and of from 2,000 16 candle-power incandescent lamps. From the particulars and information afforded to your committee they have come to the following conclusions:—That motive power, generating machinery, circuit, lamps, and other plant sufficient for 60 arc lamps of 1,200 candle-power each, and 2,300 incandescent lamps of 16 candle-power each, including £1,800 estimated cost of site and buildings, can be erected for £11,900. This estimate is based on the circuit being partly underground and partly overhead. On the assumption that the whole of the arc lights will be alight on an average nine hours per night, and that the incandescent circuit has pressure on for 18 out of 24 hours, the incandescent lamps being supplied by meter, and alight on an average 1,500 hours each per annum, the annual cost of the production of this light, including repairs, maintenance, depreciation, and interest and repayment of capital, will be from £3,300 to £3,700 per annum. Assuming that 2,000 16 candle-power incandescent lamps yield an income of about ½d. per lamp per hour, and 20 arc lamps are let out at £15 per annum each, your committee estimate that the cost of the 40 public arc lamps would be under £250 per annum. As will be seen, the number of lamps in the foregoing calculation is below the number which the plant is designed to supply, and as the demand for light increases the income will increase accordingly, which will allow of a proportionate extension of the public lighting at no greater cost. Your committee estimate that 40 arc lights would render unnecessary 180 of the existing gas lamps which at the present reduced price per lamp would cost about £450 per annum. A saving of £200 per annum would, therefore, be effected in the public lighting, while the power of the light would be many times greater. Your committee having now given, as directed, an approximate estimate of the cost of the electric lighting proposed, ask to be allowed to proceed with the matter and procure tenders to be submitted to the Council."

NOTES ON ELECTRO-MAGNETIC INDUCTION.

BY DR. J. A. FLEMING, M.A.

(Continued from page 479.)

By the aid of the ideas which were discussed in the last section we are enabled to arrive at a mechanical conception which helps us to connect together observed facts, and which, even if not a real representation of what is taking place, is at least a working model which may not be an altogether incorrect imagery of the actions taking place when an electric current is started in a wire.

An electric current on this hypothesis is a flow or progression of the electric particles which are free to move forward in a conductor, and which only can move steadily forward, owing to their incompressibility, when the circuit in which they flow is a complete circuit. Suppose a thin conductor bent into the form of a very large circle, and that an electromotive force urges a procession of electric particles round it. As these particles go forward they cause the electric *cells* next them to rotate, and the motion of this line of cells embracing the line of current will be just like that which would take place if a bracelet of spherical beads strung on an elastic thread were rolled along a round rod which it closely embraces. Each bead would turn over and over, rolling on the rod, and the motion of the whole bracelet would be like that of a tightly-fitting india-rubber umbrella ring pushed along a round ruler. The progression of the electric particles would start circular vortex rings revolving round the line of motion. This corresponds to the fact that a linear current creates a magnetic field composed of circular embracing lines of forces. The first or adjacent line of vortices would, by the intervention of the idle wheels, set in rotation another set of cells lying on a concentric line, and cause them to rotate in the same manner as the first ones. Also, it would cause a backward displacement of the intermediate idle wheels, if we consider that only the central line of electric particles are conducting matter, and that the next and all succeeding rows are in a dielectric. The starting of the progressive movement of the line of electric particles in the conductor will result in an elastic displacement in the *opposite* direction of all surrounding electric particles in the dielectric along lines parallel to the line of current; and also in setting up a system of molecular vortices composed of revolving cells, the axes of these vortices being coaxial circles described round the line of flow, the rotations and displacements being propagated out laterally from the line of current. In consequence of the fact that the revolving cells are supposed to possess inertia or mass, and that all the mechanism is supposed to be rigidly connected together, a steady force applied to set the central line of electric particles in motion will not be able to produce in them the full velocity until time has elapsed sufficient to allow the inertia of the connected mechanism to be overcome. We are thus able mechanically to imitate the phenomena of *self-induction* of the circuit and the gradual rise of current strength in an inductive circuit under the operation of a steady impressed electromotive force, and to deduce it as a consequence of the fundamental hypothesis.

Our theory, then, points out that a current should rise gradually in strength, and also that the embracing lines of magnetic force must be considered to come into existence successively as the rotation is taken up in ever-widening circles by the molecular vortices successively receiving motion of rotation. Also, on withdrawing the impressed electromotive force the inertia of the mechanism tends to make it run on for a little, and the electric particles, which by their motion started the vortices, are now themselves urged forward for a little in the same direction, and this constitutes the *extra current* at "break." Let us next endeavour to see what ought to happen on the supposition that there are two conducting circuits in the field, both forming closed circuits, and to one of which an impressed electromotive can be applied. Let V_1, V_2, V_3, &c. (Fig. 27), represent the sectional view of a series of vortex lines of electric cells, and let I_1, I_2, I_3, &c., be the idle wheels or electric particles. Let the row of electric particles I_1 be supposed to be lying inside a conducting circuit, A, represented by the dotted lines, and by our fundamental supposition, the particles I_1 are quite free to move along the conductor, and to rotate on their axes. Let there be another conductor, B, placed parallel to A, and let I_5 be the electric particles in it. The space C between is supposed to be occupied by a dielectric, and in it the electric particles can only be displaced elastically from a fixed position. We may regard these idle wheels I_2 I_3 I_4 as tethered by springs to one spot. Such being the mechanism, imagine that the row of particles I_1 is urged forward in a downward direction. As the row of particles pass between the cells V_1 V_2 they will set them in rotation in opposite directions. Owing to the inertia of the vortices the first effect of the rotation of V_2 will be to cause I_2 to roll over V_3 and be displaced in an upward direction; its displacement is resisted by the elastic force of the spring. The rotation of I_2, however, sets V_3 in rotation, and after a short interval V_3 is rotating at the same speed and in the same direction as V_2. I_2 then ceases to be displaced, because the action of V_2 on I_2, and the reaction of V_3 on I_2, simply amount to a *couple* or *twist* on I_2. The same sort of action results in a gradual handing on of the rotation from vortex to vortex, and a propagation of displacement from one idle wheel to the other. When the motion reaches the conductor B, the first result is to cause a displacement of the electric particles upwards, the rotation of V_5 not being instantly acquired by V_6. This amounts to a current in the upward or opposite direction. As soon, however, as the vortex V_6 has accepted the full speed of rotation, then the forces on the electric particles I_5 amount only to *twists*, and not to forces of displacement; hence, the particles I_5 cease to

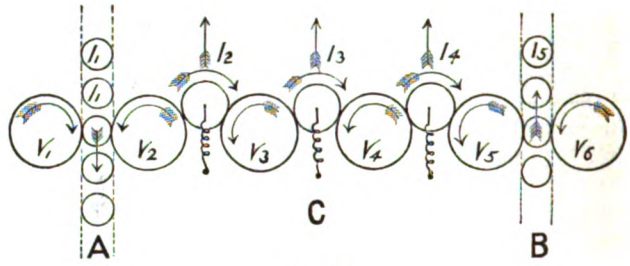

FIG. 27.

experience any force impelling them forward, and come to rest in virtue of the fact that the conductor offers a resistance to their motion. They fritter down their energy of motion into heat, and come to rest. Hence, the induction current in the conductor after a short flow ceases, and the vortex spin becomes equal in the vortices on either side of it. Suppose now that the impressed force in the circuit A is withdrawn, the electric particles in the A circuit are driven forward for a short time by the energy stored up in the adjacent vortices; these last, however, give up one by one their energy to the circuit A, where it is dissipated as heat. This surrender of velocity is propagated outwards until at the surface of the circuit B the state of things finally is, that when the vortex V_5 has come nearly to rest, the motion of V_6 still continues. The energy of V_6 and of vortices beyond expends itself in moving forward. The electric particles in circuit B, in the same direction as that in which the current in A was travelling originally—in other words, part of the energy of the field—is spent in making a transitory current in B as well as in A in the same direction. It follows, therefore, that there is a less induction current in A at breaking circuit when a circuit B is present than if B were not there—that is to say, the presence of a closed secondary circuit, B, diminishes the self-induction of the primary circuit, as is known to be the case. We see, therefore, that the theory is so far in accordance with observed facts.

(To be continued.)

A Complete History of Lightning Conductors.—The Société Scientifique et Littéraire des Instituteurs de France proposes as one of the subjects for competition this year a complete history of lightning conductors.

SIEMENS' RECORDING APPARATUS FOR COMPACT MORSE WRITING-PATENT.

The alphabet formed by the combination of two elementary signs, the "dot" and the "dash," which is used in Morse telegraph instruments of the recording type, is almost universally written in a single longitudinal line on the paper strip.

This method of writing, however, possesses the great disadvantage that the diameter of the writing disc cannot be made very small, as it would not then be certain to dip into the ink contained in the trough. A disc of comparatively large diameter, although clean in its working, is unsuitable for producing a short and sharp sign on the paper strip, particularly when the strip is moving slowly, as the tangential contact between the writing disc and the paper produces an unnecessarily long sign with a large disc, and hence the tendency to "tailing" is increased. It is for these reasons that the "dots" of the Morse alphabet can in general practice only be produced as short dashes, so that, in order to prevent misapprehension, the "dashes" require to be made longer than would be necessary if distinct dots could be produced. The writing is thus spread over far more paper than is desirable, causing not only a waste of paper but making the reading more difficult.

Various suggestions have from time to time been made with the object of remedying this defect, but owing either to complication in the methods of transmission or of reception, none of these proposals have been adopted to any considerable extent.

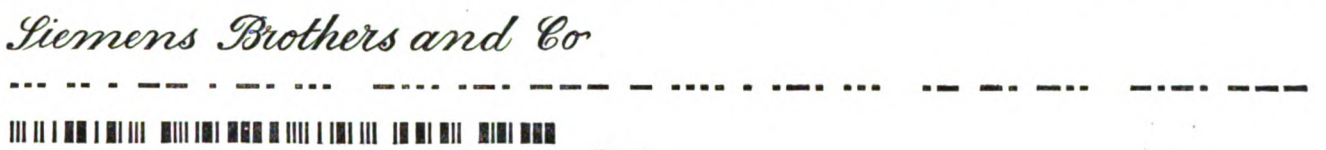

FIG 1.

The "Compact Writing" has been designed to meet the demand for improvements in the old system of Morse writing. Its elementary signs consist of lines at right angles to the edge of the paper strip and of equal width, but of different length (measured in the direction in which the paper travels), a short or thin line representing a "dot," and a longer or thicker line a "dash."

Fig. 1 illustrates the old and new system of writing, and shows the relative difference in space occupied by them. The length of paper used for the compact writing is about half that used for the old writing, while a more readable message is produced. The

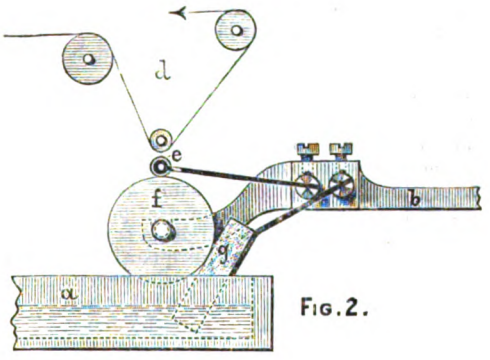

FIG. 2.

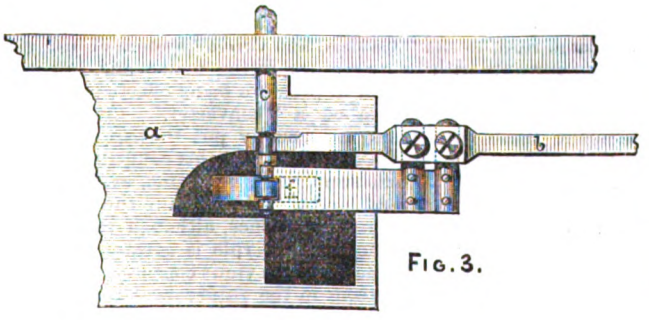

FIG. 3.

amount of paper strip to be stored away for possible future reference thus becomes considerably less—an administrative advantage not to be underrated when the present enormous increase in telegraphic communication is taken into account.

The inking arrangement by which these compact signs are produced consists, as shown in Figs. 2 and 3, of a marking roller *e*, of small diameter and of a width equal to that of the marks to be produced, mounted with its axis at right angles to the edge of the paper strip and rotated by its frictional contact with the inking disc *f*. This inking disc is carried on a spindle, *c*, resting in a bearing on the end of the armature lever *b*, and is geared with the clockwork of the instrument by which it is revolved. It is of slightly greater width than the marking roller, and has a finely grooved periphery for more effectually taking up the ink.

a is an ordinary ink trough, and *g* is a pad of felt which dips into the ink and presses against the inking disc.

The marking roller *e* and the inking pad *g* are both attached to the armature lever by flexible arms, and the amount of their pressure upon the inking disc is regulated by small set-screws.

d is the ordinary train of wheels over which the paper passes.

When the instrument is at work the end of the armature lever carrying the marking roller, inking disc, and inking pad is moved upwards by the action of the electro-magnet, the marking roller being thereby pressed against the paper, making a short or long mark, according to the duration of contact. The inking disc is rotated by the clockwork, and, being supplied with ink from the pad, carries it to the marking roller, which it at the same time causes to revolve. In this manner the marking roller receives a very even, though ample, supply of ink, and a freshly-inked surface is constantly presented to the paper, by which means, combined with the very small diameter of the roller, short, sharp, and distinct marks are produced.

The invention claim that experience has shown that any disinclination that may be felt by telegraph operators to change the method of writing the Morse code is soon removed by the conviction that the new system offers considerable advantages to themselves, and that no difficulty whatever is experienced by the change from the old system to the new.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"Lessons to be Learned from Foreign Central Station Lighting."*

BY PROF. G. FORBES, F.R.S.

I propose to deal with some of the problems of central station lighting which we in London have now to face. I judge by the practices I see common in this country that I shall, as to my opinions on many points, be at variance with some of my brother engineers, because in the work which has hitherto been done I see that the experience of foreign countries has very often been neglected, and the rule seems to be to neglect the opportunity of utilising the experience gained at great expense of time and money in foreign countries, while our progress was being retarded by the Electric Lighting Act. But my conclusions have been arrived at after a most careful consideration of the successful work which has been done in Europe and America, and I am ready to condemn foreign practice when necessary. All I say is that we ought to benefit by the experience abroad, and I know that those who have the best interests of electric lighting in England at heart agree with me.

This neglect of the principles laid down in other countries I find to exist whether the central station be used for continuous or alternating currents. I foresee great danger in store for us if we do not discuss the difficulties fully at the outset, and I trust that the discussion that this part of my Paper will give rise to will assist to make the progress now being made in England a thorough success.

Three-Wire System.

My first remarks will be about the direct system of supply at low pressure—a system which may be much more frequently employed with advantage than many people seem to imagine. It is not suited for a large district, but it has some advantages.

First. That the steadiness of the light can be increased, the fear of accidents diminished, and the amount of machinery reduced, by the employment of storage batteries.

Second. If batteries are not used the loss of energy in transformation is avoided.

* This Paper was divided into two distinct parts, of which the portion we print this week forms Part II.

Digitized by Google

Let us deal first with the case where all the dynamos are working in parallel at the same pressure. This is the Edison plan, and is very generally adopted. I have shown in my Cantor Lectures* that when we extend beyond a certain distance from the central station on the system at present used, the question of economy, as established by Sir William Thomson's law for the size of conductors must be partially abandoned, and a different size used, in order to prevent the variation of electrical pressure over the area being too considerable under the varying loads. With the "two-wire" system the law of economy holds only up to a very short distance; with the "three-wire" the distance is doubled. This is due to the fact that the pressure is doubled, and this is the principal advantage possessed by the three-wire system. In Berlin and Milan the two-wire system has hitherto been adopted, and the enormous amount of capital expended in copper is a proof of the costliness of the system. I hold that in no case of central station work at low pressure ought the two-wire system to be adopted. In this I am supported by the universal practice in America, where the two-wire system for low-pressure distribution is now totally abandoned. I am also supported in this by the practice in Berlin, where all future work is to be done on the three-wire system. In spite of these considerations, I am not aware of a single case where it is in actual use in England since the experiments at Leamington have been abandoned. The two-wire system is used at a good many places in this country. The result of experience probably is that the three-wire system can be profitably worked to a maximum limit of half a mile where the price of gas is over 5s. per 1,000 cubic feet; beyond that distance the profits diminish too much. In London I do not think it could be well done beyond 400 yards, as a general rule.

Feeders.

I now come to another principle of distribution which is strangely, and I believe almost universally, neglected in this country. I refer to the use of "feeders." Let me distinguish between the use of feeders and mains. Mains are conductors from all parts of which branches may be laid into the houses. Feeders are conductors leading from the central station to various points in the system of mains, and which are not tapped on the road. In Berlin and Milan the practice, first started in America, is followed of laying down a network of mains and supplying current at numerous points in them by means of feeders. This serves to equalise the pressure over the entire districts under varying loads In England this practice is not generally adopted. The result is that if you wander over a district supplied by electric light in England, you find that when the supply of current is small the lamps are equally bright over the whole town, but when there is a large demand for light the glow lamps near the station are far too bright and those at a distance are far too dull. In Berlin, where half the capital spent in conductors has been used for feeders, the lamps are, all over the district, equally bright at all times. Not the slightest difference can be perceived at different hours of the day or night. I hold the opinion that a station with low-tension current without feeders is badly engineered.

Using Dynamos at Different Pressures.

It is the universal practice abroad to make the size of the feeders such that the loss of pressure in these feeders is the same in all. This involves the use of very large feeders when their length is great, and great waste of energy when the length of feeder is small, but it enables all the feeders to be supplied by dynamos at the same pressure, which may therefore work in parallel. This arrangement is simple to work, but it is wasteful. I find that we can save enormously in copper at a slight extra trouble in working the central station. I would prefer to see the feeders divided into two or three groups, feeders in each group having the same length, and having the same loss of pressure. All these feeders would be made of the economical section, according to Sir William Thomson's law. When the station is at full load the dynamos working long feeders have a higher pressure than those working short feeders. When the load is light all the dynamos would work at the same pressure, because the loss in the feeders is insignificant. At such time all the dynamos might be joined in parallel, or the feeders might all be upon one dynamo.

Position of Pilot Wires.

In nearly all cases of low-pressure distribution the pressure is regulated by a "pilot wire" coming from the point where the feeder meets the main. These pilot wires indicate the pressure at those points upon a voltmeter, at the station, which is kept at constant reading by an attendant. Sometimes all the different pilot wires are grouped together at the station and indicate the average pressure on the voltmeter. This is done at Berlin. At Milan, however, the pressure is varied according to a tabular rule when the current varies. The use of pilot wires is, however, very desirable, but I hold that hitherto the pilot wires have generally been placed in the wrong position. Suppose that a 4 per cent. variation exists over the district of mains supplied by any one feeder, and that the point where the feeder strikes the mains is kept at constant pressure, then the most distant lamp supplied by that feeder has a variation of 4 per cent. If, however, the pilot wire came from a point half way between the most distant lamp and the feeder, and this point were kept at constant pressure, the maximum variation of pressure would be reduced to one-half, and would be only 2 per cent. It appears, then, that by properly placing the pilot wires the variations in pressure can be reduced to one-half; or, keeping the variations of pressure the same, the quantity of copper in the mains may be reduced to one-half.

In these suggestions as to dynamos at different pressures and as to the position of pilot wires I am supporting a course which has not been generally adopted anywhere, but the improvement ought only to be mentioned to receive general recognition.

Lamps of Different Voltage.

It has often been proposed to supply different parts of a district with lamps of different voltage. In the ordinary plan of using feeders and pilot wires the maximum pressure at the most distant lamp supplied by any feeder is the same as the pressure in the mains at the feeder. The minimum pressure may be, let us say, 4 volts less. Suppose 100-volt lamps are used, those near the feeder will always have 100 volts, but the most distant ones will have pressures varying from 96 to 100 volts. 96 volts would make the lamps very dull; and if at the distant points lamps of 98 volts were used, the pressure would never vary more than 2 per cent. from the normal, and a better light would be obtained. This would be a very good arrangement if we could lay out a district from the beginning with all the positions of the lamps established, but it is found that as the station progresses a house which would have required 100 volts yesterday may require a limit of only 99 volts to-day, owing to the introduction of additional lamps between it and the feeder. Experiments which have been made in America on this plan have led to disastrous results and hopeless confusion in completing the scheme. This plan has been completely abandoned, and in the present state of the industry I think that this abandonment has been wise.

I do not think a greater variation of pressure than 2 per cent. up and down should ever be allowed if you wish to supply a satisfactory light.

I consider that success or failure of many electric light companies now doing central station work is very much dependent on their following or neglecting the proper rules for distribution, and I will illustrate the importance of these rules by a few examples.

1. A plain network by the two-wire system, fed at the central station with the economical size of copper conductors according to Sir William Thomson's law, say, of 1,000 amperes per square inch, and going to a distance of 480 yards, would have a difference of pressure to which the distant lamps would be subjected of 24 volts.

2. On the three-wire system this would be 12 volts with one-fourth extra copper.

3. With the same amount of copper as in the last, properly arranged with feeders, the feeding points being 160 yards apart, the maximum variation of pressure in any lamp over the district is two volts if the pilot wires come from the feeding centres.

4. Everything remaining the same as this last, except that the pilot wires are placed in the proper position instead of at the feeding points, the maximum variation is only one volt.

Putting it in other words, the quantity of copper required to limit the variation of pressure over the district to a certain figure is in the last case one-twelfth part of what it is in the second case, and one-nineteenth part of what it is in the first case.

High-Pressure Distribution.

Before I leave the question of distribution, let me now apply the same rules to the "Gaulard and Gibbs" system of using alternating currents with high pressure in the mains and low pressure in the houses, the reduction in pressure being effected by means of an induction apparatus called a "converter." At the present moment these converters are usually put in parallel upon the mains. There is a general impression in this country that it is not necessary to have feeders supplying the mains, even though the distance extends to several miles. Here again the experience of other countries has been set at defiance, although in a large town like London the importance of this rule is greater than in most American cities, or in Rome. If such views continue to be adopted, the result will be as disastrous in the future as it has been in the past. In the most extensive system in this country, when there is a large demand for current, the distant lamps look like red-hot hair pins, even though the near lamps be at full brightness. This is due to defective distribution.

As already stated, there is a general belief in this country that to whatever extent the Gaulard and Gibbs system is used no trouble comes from variations of electric pressure over the district, even when the converters are placed in parallel. Let us look at this

* Cantor Lectures, "On the Distribution of Electricity," Society of Arts *Journal*, 1885.

Digitized by Google

question a little closer. Returning to the two-wire system for low pressure, if we use 1,000 amperes to the square inch as the economical section for our conductors, the fall in pressure is 5 volts for 100 yards; the loss of pressure due to the house wiring amounts very generally to 2 volts, hence the total variation between the periods of maximum and minimum output is 7 volts per 100 yards, or about double what is permissible (4 volts); hence, with the two-wire system such a size of conductor at 100 volts pressure could only be used for a distance of 57 yards. Let us see how this distance is extended by using a pressure of 2,000 volts in the mains and 100 volts in the secondary. With the same density of current the loss of pressure in the house will be now 5 volts for 2,000 yards, to which must be added 2 volts for the house wiring and about 1½ volts for loss in the converter, making 8½ volts loss of pressure in 2,000 yards.

If we allow 4 volts variation in the lamps, which is quite a maximum, this allows only ½ per cent. variation in the mains, and then the greatest distance to which conductors can extend is 200 yards. The only means of extending the district is by the use of feeders. In America the practice prevails of allowing only ½ per cent. loss of pressure in the mains. I have taken a concrete case of 1,000 amperes per square inch, which may not always apply to actual conditions, but it shows the necessity of adopting the universal foreign practice of employing feeders even with high-pressure mains.

Pressure Indicators on High-Tension Circuits.

It would be highly inconvenient to use pilot wires with the Gaulard and Gibbs system, such as are used on low-tension circuits; for this reason compound-wound voltmeters are used, which indicate the pressure at the far end of the feeder. I have described those in use at Rome and Milan; I have also described elsewhere those used by Westinghouse in America. The principle of these indicators is to have one winding connected like an ordinary voltmeter with the terminals of the dynamo, and another winding in reverse direction to carry the main current. The diminution in the indication owing to this second winding is always equal to the fall of pressure in the feeders. Different inventors have applied different classes of apparatus for accomplishing this result, but it is needless to say that the working out of such instruments takes a long time, more especially in such an instrument as that employed by the Westinghouse Company, which is made interchangeable for all circuits by the insertion of six different plugs, representing six different losses in the feeders, converters, and house wiring, varying from 3 per cent. to 10 per cent., besides four plugs for the different maximum currents in use with any feeder. I draw attention to this point because I consider that the successful working of such a central station depends largely upon the use of such an indicator of pressure; and I find manufacturers in this country who have had little or no experience in central station work prepared to equip central stations with all the necessary measuring instruments, and I wish to feel confidence that these manufacturers have realised the importance of such instruments; and I wish earnestly to impress upon them, solely in their own interests, the necessity of working out such instruments if they wish to redeem electric lighting in the metropolis from the condition into which some of the so-called pioneers of this industry have reduced it.

Insulation.

We have now to consider a very important, and perhaps the most difficult, part of the problem of central station lighting—How are we to preserve our insulation? It must be noticed that we do not require a high insulation for the sake of getting a small loss of current, but only because with many insulators the high insulation is more permanent, and permanency is the quality of insulation which is most to be desired. I am not going to discuss at present the whole question of insulation, but rather to draw conclusions from the experience of the past. At the present moment vulcanised india-rubber and okonite are the substances which have the highest reputation for durability and high insulation under all conditions. These, like other cables, are sometimes covered with lead, but in their case it is only as a mechanical protection, especially during the process of laying, because the destruction of the lead would not destroy the insulation. Of late years a class of cables has been much praised about which I wish to speak. The copper conductor, stranded or otherwise, is covered with any fibrous material, preferably jute, impregnated with bituminous oils. This covered core is enclosed in the lead pipe. In this class of cable the insulation depends upon the lead being water-tight. We all know of many places where this type of cable has done good work for a limited time, and many of us were inclined to believe that it was quite satisfactory; but I think I am right in saying that none of us know of its having worked successfully in any place for three or four years. I have said that a cable of this kind has hitherto been exclusively used in Berlin, the lead being covered with layers of tape or braid soaked in a preservative compound, and the whole armour-plated with two closed spirals of iron ribbon. I regret to have to tell you that this insulation has been a failure. It goes on well enough for about three years, then the lead gives way, the covering on the copper is permeated, and chemical or voltaic action sets up in the copper, which itself becomes disintegrated. So far as experience goes, this type of cable seems to me to be unsuitable for permanent work with the electric light. I trust that in the discussion we shall have some facts brought out. I had hoped, from what Berthoud and Borel, and also Waring, had done, that this would not be so, but the Berlin experience leads me to think otherwise; and on looking through the testimonials of makers I do not find that these cables, when placed underground, have ever worked electric light circuits beyond the three years fixed by the Berlin people as being destructive. I have been told, but I cannot believe it, that there is one company in London actually proposing to put such lead-covered cables without covering into iron pipes. Of course everyone knows they would soon be eaten into by galvanic action.

At Berlin and elsewhere I believe there is the intention of trying some modification of the system of using bare conductors, first practically used by Mr. Crompton at South Kensington. Taking economy into account, it is probable that for low-tension circuits this is an admirable plan. It is probable that it may also be adapted to high-tension circuits by using oil insulators to support the bare conductors. When copper strip is used it is necessary to raise the cover of the trough in order to increase the number of the conductors: this is very expensive. For my own part I would prefer a drawing-in system if it were otherwise equally good.

No information has ever been given as to (1) the maximum or (2) the minimum insulation resistance of the conductors at Kensington Court, but perhaps this information will be given during the discussion.

At the present moment it seems to me that the only types of underground cable proved suitable for permanent work are either bare copper supported on insulators, or else vulcanised india-rubber, or perhaps okonite. Especial care must be taken to avoid an insulator which is injured by the gases which permeate the soil of a town, or which has the property, like pitch, of becoming viscous, and so letting the copper become decentralised.

Meters.

The next lesson which the experience of foreign stations in Europe and America has taught us is the importance of charging the consumers of electricity by meter, like gas. I find that at present most companies in this country are charging the larger proportion of their consumers by contract, making an annual charge for each lamp. This appears, from evidence collected everywhere, to be a fatal mistake. It is the universal experience that those stations pay best where meters are used. In many stations it is found to be the best plan to make a fixed annual charge, which may be put down as the rent of the meter, and then an additional charge proportionate to the quantity of electric current supplied. This has the advantage of preventing customers putting in place a large number of lamps which during the greater portion of the year are idle, but which on festival occasions may all require current. Such idle lamps are very expensive to the suppliers, because a large reserve of machinery must be lying idle during the whole year to be ready for such occasions.

Within the last month I have described before the Society of Arts* the different meters which are valuable, without pretending to estimate their relative value. For continuous currents we have the Edison and Aron meters, for alternating currents we have the Schallenberger meter, and for both classes my own "Windmill" meter.

Converters.

The induction apparatus used with alternating currents is called a "converter," "secondary generator," or "transformer." The reduction of pressure from the primary to the secondary circuit is generally 20 to 1, but sometimes more. A large number of types have been invented. I have elsewhere described the Westinghouse converter, which I have tested and found to be very efficient, even though the largest one he is in the habit of supplying is only for forty lights.

Only the larger size Zipernowski converter is so efficient. Three sizes are made, varying in efficiency from 95 down to 88 per cent., though the latter is a converter suitable for twenty-five lamps. Many of the types which are made in England I feel sure are far from efficient. There is a general opinion that the loss in the converter is necessarily small. This is by no means the case. A great deal of care must be taken in the design to get a satisfactory result. I think there is a general idea that any of the converters now on the market in England will give an efficiency for the average number of lamps in circuit of about 90 to 95 per cent. I should be much surprised if there are more than two types in use in this country which have an efficiency for the average number of lamps over 70 per cent. Yet, so far as I am aware, no maker in this country ever tests the efficiency of the converters which he supplies. The effi-

* *Society of Arts Journal*, January 25, 1889.

Digitized by Google

ciency of a converter falls when it is under-loaded. If the converter in a house is adapted for 100 lamps, and only three or four lamps are in use, then, with many converters, the current which is being used is double or treble what is required for the lamps. This defect in some converters is clearly shown in the load diagram of the Grosvenor Gallery installation, where during the hours of minimum supply the current sent out from the station is seen to be abnormally high—far above that of the load diagram of other central stations—and at the hours from 4 to 6 a.m. in October current sufficient for 4,000 lamps is indicated on the station meter. This curve shows a loss of 20 per cent. The type of converter which Westinghouse has perfected is one of low magnetic resistance. The worst ones now being made in England are of high magnetic resistance. The waste in a converter, independent of magnetic friction, varies as the square of the magnetic resistance.* The waste due to magnetic friction also varies as the square of the magnetic resistance if the weight of iron is constant and the induction in the iron is the same. These high magnetic resistance converters require a great deal of copper. The magnetic friction is so great that they would probably work better with an open magnetic circuit, as shown by Lord Rayleigh (*Phil. Mag.*, 1886).

Slow and High Speed Engines.

I need hardly tell you that the most startling difference I found between the best European and American practice is the question of speed of revolution of dynamos. In America 1,000 revolutions a minute is the normal speed for an alternator of 250 horse-power; in Rome the 600 horse-power dynamos revolve at 125 revolutions per minute; at Berlin the 400 horse-power engines at 80 revolutions per minute. In Europe there is a tendency to condemn high speed as such, whereas high speed is more objectionable only in the type of machine where the revolving part is more massive, less perfectly balanced, less capable of standing centrifugal strains, and has a longer distance between the bearings. In every other point high speed is an advantage, especially in economy of plant. Now compare the Zipernowski and the Westinghouse dynamos, choosing of the former the one without Pacinotti teeth on the armature, as made by Elwell-Parker. These two machines are electrically identical, but in one the armature is fixed, in the other the field-magnets. The armature can, and the field-magnets cannot, be perfectly balanced. The weights are not very different. The armature is more capable of standing centrifugal strains than the coils of the field-magnets. For all these reasons the Westinghouse may be run at high-speed and gain all the advantages of economy. Of course the necessity of introducing belting has to be considered in this case. But then turn to the Parsons alternator, which drives direct, and being the lightest, best-balanced machine, with great capacity of resisting centrifugal strains, and with the only scientific bearings in the market. Here we have a machine where all the advantages of high-speed may be safely acquired and great economy introduced. People are apt to forget that slow speed means large machines with no increase of output.

Speed of Alternations.

Now I come to a very important point. What speed of alternations shall we use? In Rome they have 83 alternations, or 41 complete periods, per second. In America the Westinghouse Company have 267 alternations, or 133 periods, per second. What are the advantages and disadvantages, and why have these makers adopted different plans? I will answer this in detail to the best of my ability. First, Westinghouse went to rapid alternations because he wanted his converters to be of reasonable size. Second, he wanted to economise plant by using high speeds, and it would be very difficult to have slow alternations with high speed. Third, Ganz and Co. (Zipernowski) wanted to drive their machines at slow speeds, under which circumstances they cannot easily get rapid alternations. This is how these things were arrived at. Now let us see what the results are.

1. With rapid alternations the size and cost of the converters is diminished. Most people seem to think this is a small matter. A moment's consideration shows that it is not so. It is found that in most houses the size of converter does not exactly fit the number of lamps, so a size larger must be used. Hence, for a 7,500-light plant converters for 10,000 lights are required. The price of these, for the sizes used in houses, is (as the average of many makers) £5,000. The cost of engines and dynamos combined (Parsons) for the same would be about £6,000. You will now see that the cost of converters is as important as anything else.

Mr. Kapp has stated, I venture to think erroneously, that the size does not vary with the speed of alternations. This is opposed alike to experience and theory. Westinghouse knows this. I am informed that Mr. Ferranti knows it, and Mr. Zipernowski has told me so in a recent letter.

2, There is, however, an important gain by slowing the alternations. It is then easier to work in parallel. This is due to the fact that the machines have more time to get into step. If I considered parallel working essential to success, I should say, "sacrifice the cost of converters, and use slow speed." Otherwise I should say, certainly and without hesitation, "Use rapid alternations to increase the efficiency and economy."

Working in Parallel.

The experience of Rome is encouraging to anyone who thinks parallel working essential. For my part I do not. Sub-division of mains is far more practical in most cases, and enables you easily to cut out special districts if a fire or other trouble occurs. It also gets over the trouble of increased resistance in large conductors with alternating-current, dwelt on by our President in his opening address. If I have more than one station in a town, and I want one to assist the other, I would do so by trunk lines between the stations, to which a dynamo can be attached at one end and feeders at the other. Of course both stations must supply the same type of converters; hence in such a system it would not do to use dynamos of various speeds of alternations at the different stations. I would certainly prefer parallel working as being simpler for the men at the central station, if no complications are introduced to make the machines work in parallel, and if the system were equally economical, but I do not consider it at all essential. I venture to think, however, that the plan now universally proposed for making machines work in parallel will not long be tolerated. This is to introduce into the machine a large amount of injurious self-induction, thus diminishing the plant efficiency and rendering the equalising of pressure with varying loads very difficult. I have confidence in the ingenuity of our inventors, who will soon devise a less objectionable plan.

Automatic or Hand Regulation.

The question now arises whether the regulation of potential should be accomplished by hand or automatically. In all low-pressure systems, such as Berlin, it is done by hand. A workman soon gets to know at what hour special attention must be paid to this, and on the low-tension system with shunt-wound or compound-wound machines the regulation required is slight. Where the saving in attention is not very great it is always unadvisable to trust to automatic dodges. The case of alternating-current dynamos with high self-induction is very different, for the electric pressure then varies enormously with the current. In this connection such a machine resembles a series-wound direct-current machine with high resistance. The changes are so great that some automatic adjustment is necessary. Ferranti, Lowrie and others have used the sagging of a wire to effect this, and they regulate the pressure at the dynamo, not at the centres of distribution, which is wrong. The apparatus looks too delicate for an engine room. But Ganz and Co. use a very practical type. They also regulate for the centres of distribution. I also prefer the method used by Ganz and Co. of regulating the large changes by hand, and only the smaller changes automatically. This is necessary, owing to the very large adjustments necessary with alternators of high self-induction.

In conclusion, I feel confident that all those who are working to maintain England's supremacy in this department of industry will agree with me that the practical details necessary for successful central station working must be thoroughly well thought out beforehand, and that much saving of time and money can be effected by gathering hints from those who have spent years of time and tens of thousands of pounds on these details.

I frankly admit that I have learnt more that is of practical value in this line from the inspection of actual work done than by reading books.

But we must remember that the low price of gas in England, the cheapness of coal, and the relative cost of labour, all introduce special factors which will partially differentiate the English practice either from that of the continent of Europe or of America.

I wish now that the last words of this Paper may be words of thanks to the gentlemen in other countries—whether in Europe or in America—who have the control of central stations for the courtesy which they have extended to me in my endeavours to assist, to the feeble extent possible to me, in maintaining the position of this country in the progress of this new and important industry.

REVIEWS.

L'Électricité a la Maison. By JULIEN LEFÈVRE. (Paris: J. B. Baillière et Fils.)

It will be gathered from the title, and still more from the preface, that the author of this work intends it for the consumption of amateurs; hence the prominent position assigned to primary batteries, electric jewellery, and "*danseuses élec-*

Digitized by Google

triques à solenoide." The contents are multifarious to a degree unusual even in books intended for the amateur; in fact, we venture to think that its sphere of usefulness would possibly have been wider had the ground covered been less extensive. In a work ranging from Gramme machines and Belleville boilers to microscopic electric tie-pins there is likely to be a considerable amount of undigested and indigestible information. We can only recommend "L'Électricité à la Maison" to amateurs of an encyclopædic cast of mind.

Gleanings in Science: a Series of Popular Lectures on Scientific Subjects. By GERALD MOLLOY, D.D., D.Sc. (London: Macmillan and Co., 1888.)

This series of lectures affords a favourable specimen of the "popular" treatment of scientific subjects. Dr. Molloy possesses a lucid and picturesque style, and he succeeds in being at once entertaining and accurate. The lectures were delivered (on several different occasions) at the invitation of the Royal Society of Dublin. The subjects dealt with are—Latent Heat, Lightning and Lightning Conductors, The Storing of Electrical Energy, The Sun as a Storehouse of Energy, The Electric Light, and The Glaciers of the Alps. The lecture on the storage battery was delivered in 1882; it contains a good *résumé* of the general principles involved, though it is not unnaturally tinctured with what has since proved to be a too roseate view of the future. This, however, is set right by a very fair and accurate summary of the subsequent history of the accumulator down to the middle of last year. Similarly, the two lectures on Lightning were delivered in 1881, but an Appendix is added, in which the recent discoveries of Dr. Lodge and also *The Electrician* report of the discussion at the Bath Meeting of the British Association are very well summarised. The volume should amply fulfil its purpose of both interesting and instructing the general reader in some of the most important of the recent developments of Physical Science.

Notice sur le Concours 47. Électricité. (Brussels Exhibition of 1888.) (Brussels: Imprimerie des Travaux Publics.)

This is a pleasantly written account of the principal electric exhibits at the recent Brussels exhibition, and the volume forms a useful work of reference on the subject. The electric lighting of the exhibition buildings and gardens is gone into at considerable length, and several pages are devoted to the description of the remarkable display made by the military telegraph department of the Belgian army. The Dejongh telephone transmitter is alluded to in very eulogistic terms, but unfortunately no technical details are given. Under the heading of lightning conductors, the apparatus devised by M. Curtoy for the purpose of exhibiting to popular audiences some of his most striking lightning rod experiments is described at great length. Amongst other results, M. Curtoy shows that "Ohm's law with regard to electrical resistances no longer holds in the case of sparks of high tension," and that "a lightning conductor can still act as a protector even when there is a small fracture in it." "We are happy to mention in this connection," the writer goes on to say, with patriotic pride, "that quite recently the English *savant*, Dr. Oliver J. Lodge, described, in a Paper read before the Society of Arts of London, experiments confirming those of Melsens and Curtoy, and he came to the conclusion that Melsens' lightning conductor is that which complies best with indications given by theory." The book concludes with the mention of an interesting long distance indicator at Antwerp, which shows the height of the waters of the Scheldt at four different points on its banks.

The Voltaic Accumulator. By ÉMILE REYNIER. Translated by J. A. BERLY. (London: E. and F. N. Spon.)

This is a translation of M. Reynier's book on accumulators, a review of which appeared in our issue of October 19, 1888. The translation is not very well done, but as regards typography the English work is certainly a finer volume than the French original.

Electricity in the Service of Man. From the German of Dr. A. R. VON URBANITSKY. Edited by R. WORMELL, D.Sc., M.A. (London: Cassell and Co.)

This is an edition in monthly parts of the work which was reviewed in our issue of February 4th, 1887.

Index of Publications on Methods of Communication in the Field, and on Torpedo Warfare. By R. VON FISCHER TREUENFELD. (London: H. Alabaster, Gatehouse and Co.)

The great and increasing attention which is now being given to electrical communications in the field by the military authorities of Europe has naturally given rise to a voluminous literature on the subject, and it is with the laudable desire of facilitating the mastery of this important subject by military men that the author has devoted himself to the laborious task of compiling an index of publications. The work seems well up to date, and its value is greatly increased by a classification of the publications under no less than 29 heads, in addition to a most useful index to authors. We trust that the compiler will meet with sufficient encouragement to induce him to keep the index always up to date.

The Model Engineer's Handy Book. By PAUL N. HASLUCK, A.I.M.E. (London: Crosby Lockwood and Son.)

As the author remarks in his preface, "model engineering is a branch of the mechanical arts that has received but a scanty share of literary treatment." We do not think, however, that this can any longer be said. A perusal of Mr. Hasluck's useful and well illustrated little book of some 140 pages ought to teach something of model engineering, even to Macaulay's schoolboy.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, March 8th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "Notes on Mining in Spain, with special reference to the Lead Mines of Linares." By C. F. SMITH, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse, "The Discharge of a Leyden Jar." By Prof. OLIVER LODGE, F.R.S.

SATURDAY, March 9th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Experimental Optics (Polarisation: Wave Theory)." By the Right Hon. Lord RAYLEIGH, M.A., F.R.S.

PHYSICAL SOCIETY.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.

THE DIRECTORY for 1889 is NOW READY.

"THE ELECTRICAL WORLD" IN THE UNITED KINGDOM.

Arrangements have been made by which "The Electrical World" of New York can be obtained from "The Electrician" Office, 1, Salisbury-court, Fleet-street, London, E.C.

The Rate of Subscription (payable in advance), including postage, **is £1 1s. 0d.** *per annum to this Country and Abroad.*

Single Copies of "The Electrical World" can also be obtained, **price 6d. each.**

The Rates for Advertisements in "The Electrical World" of New York can be obtained on application to "The Electrician" Printing and Publishing Company, Limited, as above.

THE GAULARD-GIBBS AND THE JABLOCHKOFF TRANSFORMER PATENTS.

The judgment of the Court of Appeal in the case of Ferranti *versus* Gaulard-Gibbs can hardly have surprised any one who is at all conversant with the facts of the case. In the Court below Mr. Justice Kekewich, in pronouncing the decision annulling the patent, expressly based that decision upon a point of law, and while he certainly did express a somewhat adverse opinion both as to the novelty and as to the utility of the invention, it was the legal objection alone which led to the evidence of the patent. The Lords Justices of the Court of Appeal, whilst distinctly inclining to a more favourable view upon the points of novelty and utility, were yet entirely at one with Mr. Justice Kekewich in pronouncing the patent "hopelessly bad in law."

The specification, as originally filed on March 13, 1883, was admittedly confined to the construction and use of a particular type or types of secondary generator, which types are now, however, admitted to be commercially valueless. But the attempt made in 1886 to amend the specification by striking out the claim for a particular construction, and so extending the interpretation to the employment of any transformer, however constructed, in combination with an alternating current dynamo of high electro

Digitized by Google

motive force, traversed one of the fundamental principles of patent law. To permit a patentee, after the issue of the patent, indefinitely to enlarge the boundaries of the domain within which he holds a monopoly, would obviously open the door to unlimited abuses, and would, in fact, render the patent law impracticable. The fact that a patentee may chance to lose the reward to which he is justly entitled merely by the unskilful drawing up of his specification is one of those contingent misfortunes for which the law is obviously unable to provide a remedy.

Whether the present instance affords an illustration of such substantial though unavoidable injustice we need not now stay to discuss; we have several times already expressed an opinion upon the technical aspect of the work of GAULARD and GIBBS, and need only add that it has always seemed to us that, whilst the indirect results of their labours have been of almost inestimable value to the electrical engineer, yet the invention itself possessed little of originality, and, if it be judged by the specification, still less of intrinsic merit. It should be some consolation to the patentees to know that the Court of Appeal attaches a higher value to the technical aspect of their work than does the great majority of the electrical profession.

The practical importance of this decision, so far as its influence upon the manufacture of transformers in this country is concerned, is, however, very much discounted by the announcement now made in connection with the JABLOCHKOFF patents of 1877. Just twelve months ago (*The Electrician*, March 9th, 1888) we called attention to the fact that M. JABLOCHKOFF was entitled to the credit of having first suggested the use of a closed iron circuit in connection with an apparatus which would now be called a transformer, and was, in fact, used by the inventor for the very same purpose. In a subsequent patent (No, 1,996) of the same year, 1877, M. JABLOCHKOFF more clearly and explicitly described the system of distributing electricity by means of induction coils supplied with alternating currents. The second claim of this specification runs as follows :—

"The use in apparatus for the production of electric light, of induction coils, interposed in a primary electric circuit for generating separate and independent currents, to be used for producing electric light in one or more lamps interposed in such secondary circuits substantially as herein described."

In the drawings attached to the specification three induction coils are shown, having their primaries connected in series, and each with different numbers of Jablochkoff candles connected in series in the secondary circuits. The induction coil, or transformer, is explicity stated to be of the pattern described in the earlier patent, which, as already stated, has a closed magnetic circuit; in fact, its general design bears a close resemblance to some of the transformers in use at the present day. M. JABLOCHKOFF also contemplated having as many secondary coils as there were lamps to be lit, in which case he says "each lamp is perfectly independent and may be lit or extinguished separately." The specification concludes with the following sentence :—"As a great number of induction coils can be placed in the circuit and as a number of lamps may be placed in the circuit of each coil, it will be seen that the electric light is thus capable of very great subdivision." Altogether, apart from any controversial matter, we feel sure that every electrician will agree with us that the man who twelve years ago, and six years before the date of the Gaulard-Gibbs patent, could foresee to this extent the modern methods of electrical distribution, is worthy of our highest admiration.

Coming now to the actual state of affairs, it is already pretty generally known that the Jablochkoff patents are the property of the United Electrical Engineering Company, of which Messrs. MANVILLE and MADGEN are the managing directors. As soon as the possible value of the patent in question became apparent steps were taken by these gentlemen to obtain counsel's opinion as to its precise interpretation. A joint opinion has been given by Mr. J. F. MOULTON, Q.C., and Mr. J. C. GRAHAM (who, it will perhaps be recollected, were engaged upon opposite sides in the recent action). In this document, after pointing out that the date of the patent is prior to that of the introduction of incandescent lamps or of any lamp capable of being run in parallel, they proceed as follows :—

"We are therefore of opinion that his [Jablochkoff] claim includes any arrangement in which secondary generators of any construction are placed in parallel as well as in series, and that it also includes the use of any kind of lamp whatever, of the incandescence type."

Armed with this opinion, Messrs. MANVILLE and MADGEN were obviously entitled, had they been so inclined, to assume an attitude which would in all probability have led to further squandering of time and money in litigation, from which, as usual, the lawyers would have derived the chief benefit. On the other hand, they might have succumbed to the temptation—which did not fail to present itself—to allow their interest to pass into the hands of persons who would have pursued the advantage to the uttermost. It is, we think, very greatly to the credit of Messrs. MANVILLE and MADGEN that they did nothing of the kind. On the contrary, they have approached the trade in the most conciliatory spirit, and by dint of a tact and patience, which we cannot too much praise, the difficult and delicate negotiation which ensued were brought to a conclusion which is satisfactory to all concerned. Licenses have already been taken out by several of the leading manufacturers, and we have no reason to doubt that others will follow suit. We believe that the terms which have been made are such as to afford a fair and reasonable recognition of the supremacy of the Jablochkoff patent without pressing at all onerously upon the development of the industry. The fact that it has been possible to arrive at such a settlement by purely private negotiations speaks well for the spirit of fairness and honourable dealing which has animated all concerned.

ECONOMICS OF PLANNING AND CONSTRUCTING ELECTRIC LIGHT AND POWER STATIONS.*

BY ALEX. P. WRIGHT.

That the general application of electricity to lighting and power are to come into almost universal use is a reasonable prediction, although at present the management of a great many electric light and power companies do not appear to care for its general use, and indeed often openly say so and seek to pick and choose their customers. The time is rapidly drawing near, and, indeed, has already come to many companies, when the customers, who will use electric light or power at the present prices, will become exhausted, and the only field remaining, an extensively wide one, will be the householder, the small storekeeper, and even the mechanic or labourer in his two or three rooms—a field almost unlimited. To control this field it will be necessary to produce electric currents and to distribute them at lower rates than at present, and as important as cheap production is the prevention of the immense losses and leakages which occur, in the average of the electric plants of to-day, from expensive handling of fuel, bad firing, poor insulation, insufficiency of copper, and so forth. The savings which might be made in many cases, and the losses which might be prevented, would together pay handsome dividends on the outlay necessary for wise reconstruction, and had the planning and construction in the beginning been wise the savings would be much greater.

These articles are intended more particularly for the promoters of new companies and the directors of existing companies requiring or about to commence the extension or remodelling of their plants.

* From *Modern Light and Heat*, Boston, U.S.

Digitized by Google

Among the causes of loss and want of economy are the following :—

1. Bad location of plant, with regard to fuel and centre of distribution.
2. Cost of handling fuel.
3. Bad firing.
4. Cost of water.
5. Friction and loss in transmission of steam and mechanical power.
6. Bad designing and division of power and current generating units.
7. Loss from insufficiency of distributing copper.
8. Leakage from use of poor insulation and poor construction.
9. Unwise rates and discrimination as to selection of customers calculated to head off profitable business. All more or less due to false economy in purchase of material and construction.

The first consideration in organising for the lighting of a town or city is the determination of the requirements, as far as present and near future lighting are concerned, both as to the number of lights and the duration and times of their use, bearing in mind that the consideration of future business does not of necessity mean immediate expenditure, but rather the prevention of large expenditures when the time comes for extension, and that removal of a whole plant or reconstruction of the original plant may not be necessary to accommodate extension. These considerations are necessary in order that the amount of apparatus may be determined and a preliminary plan and sketch made as a basis upon which to estimate the capital required for the enterprise, and in order that the probable cost of maintenance and running expenses may be arrived at, with a view to the preparation of a schedule of rates which, whilst profitable to the company may be equitable to the consumer, and of such a nature as to bring business.

The choice of a site for the location of an electric light or power station requires great judgment, and it is here that usually one of the strongest evidences of false economy exists. A very general idea has been that any place would do for an electric light station as long as it was cheap, and so it would not matter where located, or at how low a rate purchased, if subsequent cost is to be disregarded. Primarily, secure a location immediately adjoining coal transportation, and, if possible, water, chosen with a view to the economical handling of fuel, as well as room for abundant storage. . . .

Purchase sufficient land for station, storage, and future increase ; and do not attempt to do what has been so often done, design a station to suit a lot—rather buy the lot to suit such a station as may be designed. Get near water if possible ; even if it is not at first intended to use condensing engines, it will eventually be done when increase comes if water can be obtained cheaply. The saving to be made in the handling of coal, and condensing even on a small power, will pay interest on quite a large capital for more than would be required in the majority of cases to attain good results. If coal has to be hauled, if only a short distance, it will cost from 40 cents to 50 cents a ton for haulage and handling ; it will rarely cost less than 40 cents. Suppose an average load to be 150 horse-power for street lighting, running, say, an average of ten hours per day all the year round—that is, for 3,650 hours per annum. If the average coal consumption were 4 pounds of coal per hour per horse-power (it averages more than this all over the country), 600 pounds of coal per hour would be required, or 2,190,000 pounds of coal—that is, 1,095 tons—which would cost for hauling at 40 cents per ton $438.00, six per cent. interest on $7,300·00. If water were used for condensing, twenty per cent. of fuel might be saved on 219 tons ; if fuel cost $4.00 per ton a sum of $876.00 might be credited to maintenance, or six per cent. on $14,600.00, in all $21,900.00, far more additional capital than would be necessary to expend to make the saving. The fact of condensing will increase the capacity of boilers, heaters, and pumps, or if desired a saving in expenditure would follow here, as well as an engine, which by condensing is also increased in power. At present it is not proposed to deal with the cost of construction, but rather to show what may be saved, which will amply repay for increased cost of construction, as will, it is trusted, be demonstrated later on, as well as leaving a margin for handsome dividends, and at the same time an opportunity for a reduction in rates which is so necessary to the attainment of a large general lighting business.

Whilst dealing with the matter of the location of a station, it must be borne in mind that the question of cost of copper for distribution and general line work must be considered. It will pay to expend some extra money in this direction to secure cheap handling of fuel, and reduction in its consumption ; but this may be carried too far, and the extent to which it is carried will depend upon cost of coal, amount of lighting, and many other details peculiar to the particular case under consideration.

Bad firing usually comes from the employment of cheap, and, therefore, inefficient help—another instance of parsimony in management. The majority of folks have an idea that any labourer taken off the streets will make a good fireman. So a great many of them will, but when they become so, they will seek other places unless paid in accordance with their skill. A saving of twenty-five or fifty cents a day in firemen's wages will result in a very much increased consumption of fuel. In some respects the fireman is more important than the engineer, for it is at the shovel probably that the largest savings in running expenses can be made. Listen and leave the constructing engineer alone when once a plan has been decided upon. Do not interfere with details or force poor material upon him, and the result will be a very much reduced cost of maintenance as compared with the average of electric light stations.

Taking a sample case, which is nearly similar to one that actually exists, it may be interesting to carry out the system outlined above, making estimates of cost of construction, running expenses, maintenance and income. The example to be considered is a case where the immediate amount of street lighting to be obtained amounts to 60 full arc lights (2,000 candle-power), running all night and every night with a certainty of at least 30 lights increase in twelve months, and in a territory requiring at least 360 street lights. In addition to this about 170 1,200 candle-power divided arcs will be used for commercial lighting.

A plant of 3,500 incandescent lamps capacity of 16 candle-power lights will be required immediately, with a prospect of very rapid increase, provided rates are suitable. Thirty-five horse-power of motors can be placed at once, with prospects of at least doubling that amount in twelve months with good management.

The conditions of commercial lighting are as follows : Stores close at 6 o'clock generally on four and five nights of the week, and at 10 and 11 o'clock on one or two nights, except during the holidays, when they close at 11 and sometimes 12 o'clock every night. A number of the stores keep their window lights running until 11 o'clock every night. There are a few halls and churches requiring occasional lighting, a considerable amount of incandescent lighting in basements and in stores on dark days, necessitating running during the twenty-four hours.

The majority of the lighting is in stores, some hotel lighting and some business lighting in banks and insurance offices, closing at 4 and 5 o'clock, while the prospect of house lighting is very good.

Summarising the dynamo capacity required for such a station, we find that the power required will be as follows :—

		H.-P.
60	Full arc lights (2,000 candle-power) for street lighting ..	60
170	Divided arc lights (1,200 candle-power) for commercial lighting	125
3,500	16 candle-power incandescent lamps	350
35	Horse-power motor capacity	35
	Total horse-power	570

Before determining the size of lot required it will be necessary to prepare a preliminary sketch of buildings, and to do this the capacities and number of the various dynamos and their arrangement must be settled, to provide sufficient space for them. The question of the subdivision of power has also to be considered, in order that the capacities and dimensions of engines may be arrived at before designing the engine room, and finally the amount of increase of business to be allowed for, in order that the dimensions of the various rooms and their combination in one building may be planned.

The units of power, which will be the most important element in economy, can be best determined by setting out graphically the variations in power during the 24 hours. These under the particular conditions assumed will be on Saturday in the winter, when the heaviest loads and those of longest duration are to be expected, and for which of course the work must be primarily arranged ; for the remaining days in the week the subdivisions of power will be the same, the duration of the heavy evening load being shorter, commencing to drop more rapidly at 6 o'clock and continuing to do so until 9 o'clock, when it drops more slowly again to the ordinary night load.

The accompanying curve has been very carefully laid out from the conditions assumed with the aid of over 12 months' records of a station working under similar conditions.

The vertical seal is the power seal in units of 100 horse-power, and the top horizontal scale represents time, in divisions of 2 hours. Commencing at 12 o'clock at night, the power required is uniform until the early morning, when the incandescent load begins to rise ; at six o'clock, when the motors are put on, there is a sudden rise in the curve ; a little later the street lamps are cut out, which causes another drop ; meantime the incandescent load is rising until the stores are opened, then there is a gradual decline until the load again becomes uniform until 12 o'clock noon, and the motors are stopped until one o'clock, as indicated by the curve line. After one o'clock the load is again uniform until towards dark, when the incandescent load begins to increase rapidly. The commercial arc lights are thrown into circuit and finally the street lights, and at six o'clock, when the maximum load has been attained, for a short time the motors are cut off, as indicated by the vertical drop in the curve, followed by a slight reduction in the incandescent load ; at

Digitized by Google

about nine o'clock there is a perceptible reduction in the incandescent load, and the incandescent and commercial arc load begin to fall with increasing rapidity until 12 o'clock, by which time the night load reaches its normal position.

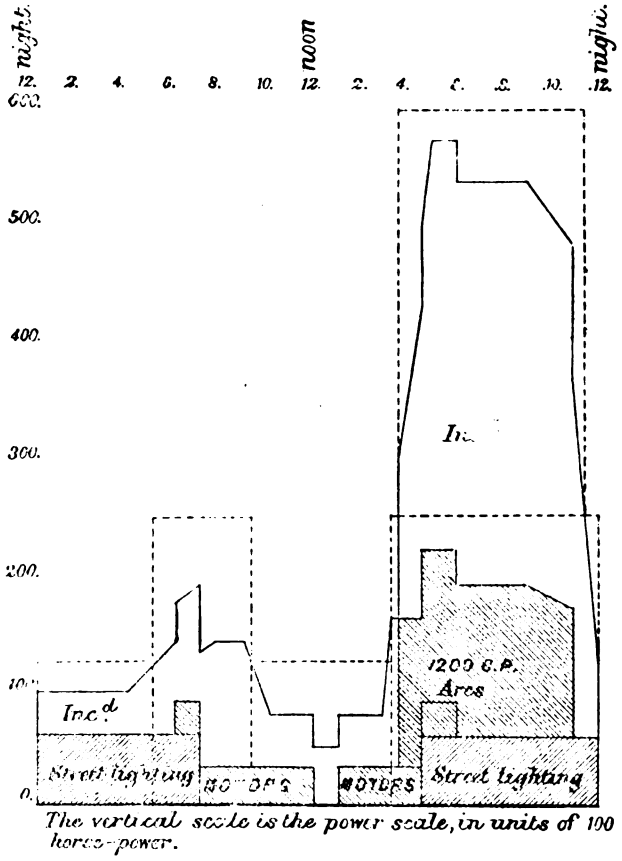
The portions of the total power used at any given time for 2,000 candle-power (street lights), 1,200 candle-power (commercial lights), motors and incandescent lights are all indicated on the curves, as will be readily understood when the diagram is examined.

The determination of the units of power into which the engines may be divided in order to keep any one, two, or three engines loaded within their economical range may now be determined, and is indicated by the dotted horizontal and vertical lines in the diagram, the horizontal lines obviously showing the duration of each load, and the vertical dotted lines the starting and stopping of each engine. It will readily be understood that such a division of power will require shafting and an arrangement of cut-off friction couplings, which will enable the changes in the engines to be made without shutting down dynamos, and also in order that the portions of shafting required at any time may be cut in or out. Proceeding at first on this assumption, we determine that engines of the following capacities are required, viz. :—

125 horse-power for night and normal day load.
250 horse-power for morning and first portion of afternoon and latter part of evening load.
350 horse-power for duration of heaviest load to be used in conjunction with the 250 horse-power engine.

725 total horse-power.

On Sundays and holidays the 125 horse-power engine and the 250 during the evening will suffice.



The vertical scale is the power scale, in units of 100 horse-power.

In the summer it will be found that except on Saturday evenings the 250 and 350 horse-power engines will rarely come into use together.

The arrangement of three such engines in an engine room would require a space of about 45ft. by 60ft., allowing for some increase in engine capacity by the removal of the 125 horse-power engine to be replaced by a 600 or 700 horse-power engine, which would allow for an increase about doubling the capacity of the plant.

A boiler room having an ultimate capacity of 1,300 horse-power, with, say, one additional boiler of 125 horse-power, would require a space of 45ft. by 100ft.

If the dynamos are placed above the shafting, a dynamo room, 34ft. by 75ft. or 80ft., would be ample for 1,300 horse-power of machines.

A building occupying about 100ft. by 80ft., with an extension for boiler room of 50ft. by 60ft., would probably suit.

A lot from 160ft. to 200ft. by 100ft. would be suitable.

The dynamos required are as follows :—

2 30 full arc lights (2,000 candle-power).
4 45 divided arc lights (1,200 candle-power).
1 80 horse-power motor generator
1 650 light incandescent alternating dynamo.
2 1,500 ,, ,, ,,
2 Exciting dynamos each of capacity capable of exciting the fields of all the alternating dynamos.

Preliminary estimates are necessary of the cost of such a plant, the amount of fuel required, assuming that the two large engines are compound condensing and the small engine a condenser ; and an estimate of the cost of maintenance and running expenses, to which being added a fair dividend, after estimating the number of horse-power-hours produced per annum, the rate per horse-power can be readily arrived at, and from it rates determined for each class of work, which will pay a sufficient profit to induce the investment of capital.

The cost of such a station would be, say, about as follows :—

Property	from $15,000 to $20,000
Buildings and foundations	20,000
Chimney	4,500
Arc dynamos and lamps	23,000
Incandescent dynamos and lamps	36,500
Motor generator motors and adjuncts	10,000
Mem. These items include station wiring and fitting.	
Engines and foundation including condensers, &c.	25,000
Boilers and settings, steam piping, pumps, injectors, feed-water heaters, &c.	20,000
Shafting, pulleys, clutches, &c.	4,000
Belting	4,000
Pole lines, pins, insulators, cross arms, wire and outside construction	50,000
Office and stone room fitting and sundries	1,000
Tools, &c.	1,000
Total	$229,000

Capitalise at, say, $230,000.

Proceeding now to estimate the cost of operating such a plant, primarily determine, as being most important, the labour required, and the total horse-power-hours developed in order to arrive at fuel consumption.

The superintendence and labour will be about as follows :—

	Per annum.
Superintendent and manager	$3,000.00
Assistant superintendent	1,200.00
Accountant	1,000.00
Office boy	250.00
Chief engineer	1,500.00
Two Assistants	1,800.00
Two dynamo attendants	1,800.00
Two Oilers	1,500.00
Three Firemen	2,100.00
One Labourer	730.00
Three Trimmers	2,190.00
One Lineman	780.00
One Incandescent Wireman	780.00
One Boy (to assist Wireman)	300.00
	$18,930.00

These salaries and wages may appear high to many, but we are assuming that all work is to be of the best, and all *employés* of a high class.

(To be continued.)

THE PHYSICAL SOCIETY.

Electrical Measurement.*

BY PROFS. AYRTON AND PERRY.

(Concluded from page 490.)

The Paper next described the experiments that had been made to determine the exact law of variation of the effect of a layer of wire in their ordinary magnifying spring instruments with the distance of the layer from the axis, and to determine the best thickness of winding to employ in one of their instruments, and the authors found that whereas a given deflection could be produced with the least expenditure of watts when the radial thickness of the winding was very small, the ratio of cooling surface to watts expended increased with the radius of the bobbin. Hence the later instruments being wound to a greater radial depth than the earlier

* Abstract of Paper read at the Physical Society, February 23rd.

Digitized by Google

ones enabled a given deflection to be maintained with a less rise of temperature of the instrument. They next described how the experiments had led them to see that the permanent magnetism error of a given piece of iron when used in a measuring instrument, and which tended to make the readings for an ascending current less than for a descending current, could be diminished by altering the depth of the winding. The method that they had employed at the Acme Works of constructing a standard d'Arsonval instrument, which could be used to measure currents from a fraction of an ampere up to 600 amperes, and a P.D. up to 500 volts, such that the motion of the spot of light over the scale was never less than 4½in., even when the smallest current or P.D. was being measured, was referred to, and the difficulties they had met with in arranging a d'Arsonval instrument so that the deflection from one end of a three-foot scale to the other should be strictly proportional to the current, was described, as well as the method by which these difficulties had been overcome by their assistant, Mr. Bourne, by allowing the coil to hang freely from a torsional suspension above the coil, and arranging an extremely elastic non-directive suspension to lead out the current at the bottom.

Tests of the exact constancy of the ratio of current to square root of deflection of a Siemens dynamometer were then described, and it was shown that in consequence of a slight distortion of the spring in the dynamometer which occurs in all the dynamometers they had tried for a rotation of the milled head through even 180deg., the constant of the instrument was not really constant, but varied as shown below, a deflection of 400 divisions corresponding with one complete rotation of the torsion head.

Deflection.	Current. / √Deflection.
21·5	1·080
54·3	1·085
121·2	1·090
188·7	1·092
270·5	1·095
334·5	1·093

Prof. Ayrton, who gave an abstract of the Paper at the meeting, then referred to the modified Cardew voltmeter, devised by Prof. Perry and himself, and described in a Paper read before the Society of Telegraph-Engineers and Electricians at the end of 1887. He stated that the results of a long series of experiments had led to an important correction in the equations worked out in that Paper, and mentioned that by taking advantage of this correction they had been enabled to construct voltmeters to measure potential differences as low as one volt to within a hundredth of a volt, such as the instrument shown in the accompanying illustration, and which had been especially devised for measuring the alternate P.D. at the terminals of the secondary coil of a Thomson and Houston electric welder, which they found by experiment to be between one and two volts. It indicates up to 2·16 volts, which produce a rotation of the pointer through 360°. An instrument was also shown giving the same rotation for a potential difference of eight volts.

The extreme sensibility of this type of voltmeter was demonstrated by using it to measure the E.M.F. of an accumulator and the fall of the P.D. at its terminals when the accumulator was sending a current. The E.M.F. of the accumulator used was shown by the hot wire voltmeter to be 2·07 volts, and the P.D. fell to 2·03 volts when the current sent, as measured by one of their ordinary magnifying spring ammeters, was 10 amperes. Hence the resistance of the accumulator was

$$\frac{2\cdot07 - 2\cdot03}{10}, \text{ or } 0\cdot004 \text{ ohm.}$$

The error referred to in the investigation previously made was the neglect of the alteration of the length of the platinum-silver wire due to the alteration of stress as the sag of the wire varied,

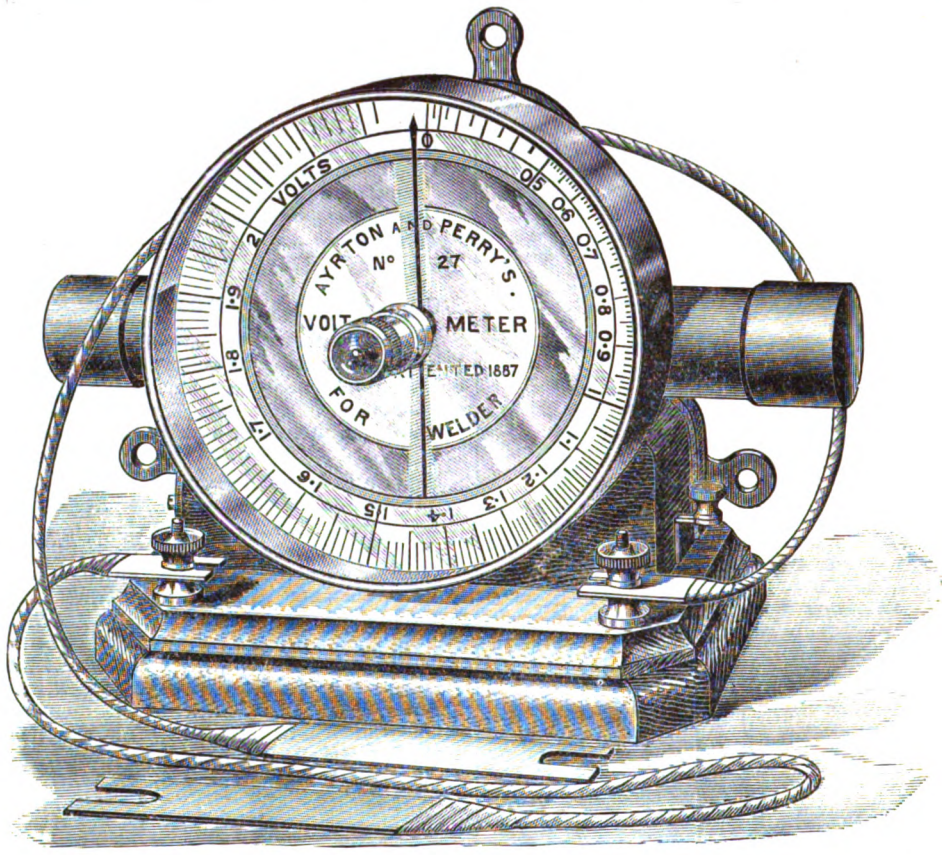

Fig. 1

for the authors believed that the stress in the wire was too small for the alteration of length due to the diminution of stress in the wire expanding to effect the alteration of sag produced by the application of a given P.D. They remarked that their having omitted to take into account this effect of the alteration of stress was the more curious since one of them pointed out in *The Electrician* in the autumn of 1887 the importance of not neglecting it in the case of the telegraph wires, and showed how the compensating action, thereby introduced, enabled the dip of a telegraph wire in summer to be made much less than would be possible without the wire breaking in the winter if the simple change of length of the wire by change of temperature were alone considered. In the early part of 1888, however, they found that the change of stress produced a sensible effect in diminishing the increase in length in the fine platinum-silver wire of their voltmeter which would otherwise be produced by the change in temperature. The result of a long series of experiments, which have since been confirmed by a complete mathematical investigation, showed that with a given magnifying spring the rotation of the pointer for a given P.D. applied at the terminals of a given wire varied, as shown by the following figure, No. 2, when different initial sags were given to the wire, and they

Digitized by Google

found that with a particular wire, pulled with a particular magnifying spring having a certain definite initial tension, there is a certain initial sag for which the sensibility of the instrument is a maximum, and the authors have, therefore, endeavoured to adjust the initial sag of each instrument so as to give the maximum sensibility.

Another important effect of the alteration of stress with alteration in the sag is that the temperature coefficient of the tube to the ends of which the wire is attached depends on the initial sag. This is a decided advantage, as the tubes can be made of copper and iron in fixed proportions, and finally adjusted by adjusting the initial sag until no change in the zero position of the pointer, as well as no change in the deflection due to a given number of volts, is produced by warming the instrument as a whole, thus reducing the temperature error to a minimum.

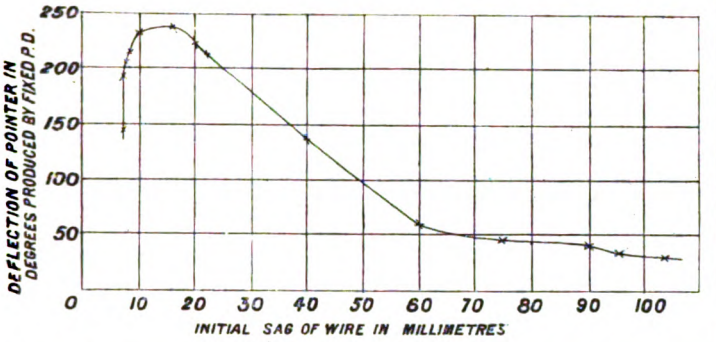

FIG. 2.—Experimental Hot-Wire Voltmeter. Length of Platinum Silver Wire, 208mm.

Fig. 3 shows a horizontal section of the instrument as at present constructed by the Acme Works. In the original instrument the pull of the magnifying spring M was counterbalanced by the pull of the platinum-silver wire W W attached to the blocks B B ; but, to save space, both these pulls on the present instrument act in the same direction, and are counterbalanced by the flat spring M. Hence, as the wire stretches the magnifying spring M is stretched, and the pointer P P, to which a number of fine hairs are attached to introduce damping without solid friction, rotates. The flat spring is not only introduced to enable the depth of the instrument to be diminished by twice the sag of the wire, but to enable a particular arrangement of force to be employed. In the ordinary Cardew instrument, with its two yards length of wire, the introduction of a short fuse which will melt with a current too small to damage the instrument does not seriously increase the resistance or diminish the sensibility, but in Profs. Ayrton and Perry's hot-wire voltmeter, which contains only 8in. of wire, the introduction of such a fuse would diminish the sensibility ;

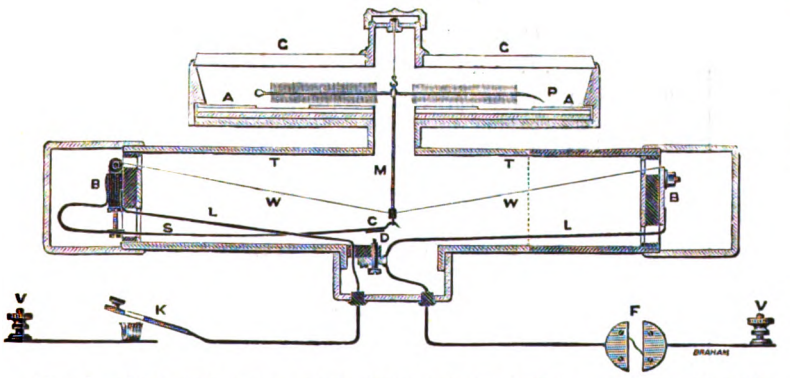

FIG. 3.—Horizontal section of the latest pattern Ayrton and Perry Hot-Wire Voltmeter.

and it is practically impossible to diminish the length of the fuse wire in proportion to the length of the working wire, as the conduction of heat by the metallic blocks, to which an extremely short length of wire is attached, prevents its quickly melting. Hence, they employ a fuse, F, of such a diameter that it would require a far larger current to melt it than would damage the instrument, and they arrange in addition a platinum-tipped screw, D, so that when the wire W W stretches by any prearranged percentage beyond the amount it stretches for the maximum safe P.D., the platinum tip C of the flat springs comes into contact with the screw D, and the working wire is short-circuited. The circuit is then temporarily completed through the lead L, to the left, the flat spring S and the fuse F, when the current increases and the fuse melts without damage to the instrument. With this device they find that the fuse may be thick, and, therefore, have but a small resistance compared with that of the working wire, and yet the sudden application of a P.D. five or six times as great as the maximum P.D. the voltmeter is intended to measure, melts the fuse without damaging the working wires. For clearness, the fuse, the key, and the terminals V, V are shown detached from the instrument, but they are in reality in the base, as seen in Fig. 1.

ON THE DESIGNING OF CONTINUOUS-CURRENT DYNAMO MACHINES.

BY PROF. JAMIESON, M.INST.C.E., F.R.S.E.

(Concluded from page 489.)

Proportioning of Ampere Turns between Shunt and Main Coils.—The total ampere turns have now to be divided in proper proportion between the series coils and the shunt coils of the field-magnet windings.

In order to do this, so as to give the desired form of characteristic curve, we must have recourse to actual experiment. The following method is carried out by Messrs. M'Whirter, Ferguson and Co., Faraday Works, Govan :—

1. A workshop bobbin or experimental coil, with a known number of turns of wire, is kept for every size of dynamo machine made. This bobbin is put on to the magnet core in circuit with an ampere-meter, and is separately excited by another dynamo or storage cells. The dynamo to be wound is run at the normal speed with the external circuit R_e, equal to that of shunt, viz., 77ω, and with the voltmeter placed between the terminals. The exciting current through the experimental bobbin is now gradually increased until the required number of volts is observed on the voltmeter. *E.g.*, suppose the experimental bobbin to have 500 turns, and the ampere-meter reads 8·25 amperes, when the normal voltage of 100 volts is reached, then the ampere turns of shunt wire

$$A \times T_{sw} = 500 \times 8{\cdot}25 = 4125 \text{ ampere-turns.}$$

2. Connect up the armature of the dynamo being constructed to a resistance equal to the joint resistance of the shunt and the normal lamp circuit through an ampere meter, and run the dynamo at the normal speed. Now increase the exciting current in the experimental bobbin until the normal voltage of 100 volts and normal armature current of 65·3 amperes are both obtained. At the same time observe the exciting current.

But, the total required ampere-turns = 6875, and from experiment (1) we found that 4,125 ampere-turns produced the requisite E.M.F.

$\therefore$ 6875 − 4125 = 2750 ampere-turns left for series coils.

3. The normal current at full load required to pass through the series coil was found to be 65·3 amperes.

Consequently the number of turns required in the series coils

$$= \frac{2750}{65{\cdot}3} = 42 \text{ (about).}$$

4. From experiment (1) we found that 4,125 ampere-turns gave us the required excitation to produce the normal E.M.F., and from our former calculation we found that the current in shunt,

$$\therefore \frac{4125}{1{\cdot}3} = 3173 \text{ turns.}$$

$$C_s = 1{\cdot}3 \text{ ampere.}$$

But the series coils are also carrying the 1·3 ampere required for the shunt when dynamo free.

$\therefore$ 3173 − (42 turns × 1·3 a) = 3173 − 54 = 3119 turns on shunt coils.

5. All we now have to do is to so proportion the size of our series and shunt coil conductors that they shall carry the necessary currents required in each case at the rate of not exceeding 1,000 amperes per square inch. For armatures this may be and is in practice increased to even 3,000 amperes per square inch without undue overheating, owing to the cooling effect of the air carrying off the heat generated in the revolving armature. Mere radiation only acts on the field-magnet coils ; therefore the sectional area is of necessity much greater.

Example 2.—Now take the case of a Rankin-Kennedy short-shunt compound dynamo. The particular dynamo in question was tested by the writer after completion with the following results :—

Resistance of armature, warm	R_a	= ·04 ohm.
Resistance of magnet shunt, warm	R_s	= 20 ohms.
Resistance of magnet main coil, warm.....	R_m	= ·03 ohm.
Current in working circuit.....	C_c	= 108·5 amperes.
Current in shunt-magnet coils	C_s	= 5 amperes.

Digitized by Google

Difference of potential at dynamo terminals E_e = 100 volts.
Difference of potential at brushes ..... E_b = 103 volts.
E.M.F. generated in armature ..... E_a = 108 volts.
Turns of armature wire ..... T_{aw} = 180.
Number of armature revolutions per minute N_{ar} = 620.

Electrical Efficiencies.

External electrical power, or "output," available for electric lighting, &c. $= C_e \times E_e = 108{\cdot}5_a \times 100v = 10{,}850$ watts $= 88{\cdot}7\%$
Power absorbed by armature $= C_a^2 \times R_a = (113{\cdot}5)_a^2 \times {\cdot}04\omega =$ 515 watts $= 4{\cdot}2\%$
Power absorbed by shunt magnet coils $= C_s \times E_s = 5_a \times 103v =$ 515 watts $= 4{\cdot}2\%$
Power absorbed by main magnet coils $= C_m^2 \times R_m = (108{\cdot}5)_a^2 \times {\cdot}03\omega =$ 353 watts $= 2{\cdot}9\%$
Total e'ectrical power,
$(C_e \times E_e) + (C_a^2 \times R_a) + (C_s \times E_s) + (C_m^2 \times R_m) =$ 12,233 watts.

the only difference between this dynamo and our last example being that the magnet core was made of the best hammered scrap iron instead of cast iron, and consequently the permeability is greater. The constants to be used in the formula are therefore less, and we have to substitute 2 for 3, and 1,500 for 1,800 as found by experiment.

From the measured dimensions of the dynamo we found :—

$L_m = 38$ inches. $S_m = 98$ square inches.
$L_{as} = 0{\cdot}45$,, $S_{as} = 195$,,
$L_a = 15$,, $S_a = 46$,,

$$\therefore R_m = 2\frac{L_m}{S_m} = 2\frac{38}{98} = {\cdot}76,$$

$$R_{as} = 1500\,\frac{2\,L_{as}}{S_{as}} = 1500\,\frac{2\times{\cdot}45}{195} = 6{\cdot}9$$

$$R_a = \frac{L_a}{S_a} = \frac{15}{46} = {\cdot}33.$$

Total magnetic resistance = 7·99.

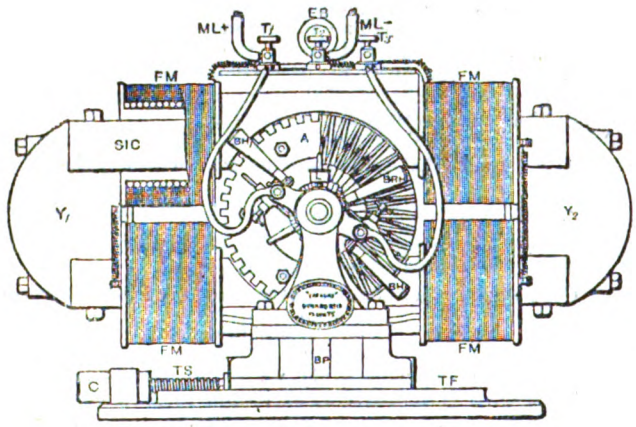

Fig 2.

B P, Bed Plate ; T F, Tightening Frame ; T S, Tightening Screw ; F M, Field Magnets ; Y_1 Y_2, Yokes (cast iron) ; S I C, Soft Iron Cores ; A, Armature ; B H_1 B H_2, Brush Handles ; M L+ M L−, Main Leads ; T_1 T_2 T_3, Terminals.

Now, by substituting in our former formula the actual values obtained for the E.M.F. in the armature, turns of armature wire, and revolutions per minute, we get the magnetic flux in Kapp lines flowing through the armature. Or,

$$K_{La} = \frac{E_a}{T_{aw} \times N \times 10^{-6}} = \frac{108}{180 \times 620 \times 10^{-6}}$$

= 968 *lines of magnetisation through armature, or at the rate of* 21 *Kapp lines per square inch.*

But in dynamos of this class it has been found that the number of magnetic lines passing through the armature are only 80 per cent. of the total magnetisation in the field-magnets. Consequently,

80% : 100% :: 968 : x

$\therefore x = 1210$ *Kapp lines through the magnet cores, or at the rate of* 12·3 ***Kapp lines per square inch.***

From our former formula,

$$K_L = \frac{A \times T_{mw}}{R_m + R_{as} + R_a}$$

$$1210 = \frac{A \times T_{mw}}{7{\cdot}99}$$

= 9668 ampere turns on the field-magnets.

The actual ampere turns were 9,800, or the calculation is only about 1 per cent. less than the *actual* amount required to satisfy the requirements of the installation.

Example 3.—Take the case of a Faraday compound dynamo, also tested by the writer, supplied by Messrs. M'Whirter, Ferguson and Co., Govan, to the Blair Lodge School, where (*see* Fig. 2)

$R_a = {\cdot}0315\,\omega$ $E_e = 100v$
$R_s = 31{\cdot}0\,\omega$ $E_a = 107{\cdot}6v$
$R_m = 0{\cdot}012\,\omega$ $E_b = 102v$
$C_e = 130{\cdot}0\,a$ $T_{aw} = 240$ (48 commutator bars)
$C_s = 3{\cdot}55\,a$ $N_{ar} = 800$

This dynamo being of the double horseshoe magnet type, and the cores being of the best Swedish iron, with large cast-iron yokes, we use a constant 2 for wrought-iron cores, and 1,440 for specific resistance of copper and air space due to wrought cores and pole-pieces.

From the actual dimensions of the dynamo we found :—

$L_m = 32{\cdot}0$ inches. $S_m = 33$ square inches (only 1 magnet core).
$L_{as} = 0{\cdot}5$,, $S_{as} = 54$,, ($\frac{1}{2}$ air space surface).
$L_a = 12{\cdot}0$,, $S_a = 15{\cdot}6$,, ($\frac{1}{2}$ section of armature).

$$\therefore R_m = 2\frac{L_m}{S_m} = 2\frac{32}{33} = 1{\cdot}94$$

$$R_{as} = 1440\frac{2\,L_{as}}{S_{as}} = 1440\,\frac{2\times{\cdot}5}{54} = 26{\cdot}6$$

$$R_a = {}^*2\frac{L_a}{S_a} = 2\frac{12}{15{\cdot}6} = 1{\cdot}54$$

Magnetic resistance of half-dynamo field = 30·08

Now,

$$K_{La} = \frac{E_a}{T_{aw} \times N_{ar} \times 10^{-6}} = \frac{107{\cdot}6}{240 \times 800 \times 10^{-}}$$

= 530 *lines of magnetisation through armature, or at the rate of* $\frac{530}{15{\cdot}6 \times 2} = 17$ *Kapp lines per square inch of armature section.*

Allowing, as before, that only 80 per cent. of the total magnetisation passes through the armature, we have

80% : 100% :: 530 : x.

$x = 662$ Kapp lines through both the magnet cores, or 331 lines through each half, which is at the rate of 10 Kapp lines per square inch of magnet core section.

$$\therefore K_L = \frac{A \times T_{mw}}{R_m + R_{as} + R_a},$$

Or $A \times T_{mw} = K_L\,(R_m + R_{as} + R_a$;

$\therefore A \times T_{mw} = 331 \times 2 \times 30{\cdot}08 = 19913.$

The actual ampere turns were 20,850, and the dynamo having a rising characteristic of 3 per cent., the calculation is only about 1·7 per cent. less than actually found by experiment.

LEGAL INTELLIGENCE.

In re Gaulard and Gibbs' Patent.

JUDGMENT.

COURT OF APPEAL.

(Before Lords Justices Cotton, Lindley and Lopes).

This appeal of Lucien Gaulard and others against a judgment pronounced by Mr. Justice Kekewich on July 9th, 1888, in the case of a petition for the revocation of certain letters patent which were granted to Messrs. Gaulard and Gibbs on the 13th September, 1882, came up for decision on Monday last.

LORD JUSTICE LINDLEY, in delivering the judgment of the Court, said this was an appeal from an order made by Mr. Justice Kekewich, by which he declared in substance that the patent claimed by Gaulard and Gibbs was invalid. That order was made under Section 26 of the present Patent Act, which had substituted a modern mode of procedure for the old one of *scire facias* to repeal letters patent. The objections taken to the present patent were the following :—First that, having regard to the previous state of

* 2 here is on account of the double field, or the magnetic lines or circuit entering from each side.

Digitized by Google

knowledge, the patentees' invention was not one for which a patent could be obtained; secondly, that the complete specification was not for the same invention as that described in the provisional specification; thirdly, that the nature of the invention was not "particularly described and ascertained" by the complete specification; fourthly, that the complete specification had been so enlarged by amendment as to destroy the patent; fifthly, that the patented invention was not new. This last objection was so connected with the first as really to merge into it. In order to deal with these objections, the first thing to be done was to discover what the invention really was according to the patentees' own description of it. For this purpose the complete specification in its original shape ought to be studied in the first instance rather than the provisional specification, for the former document "particularly described and ascertained" the invention, whilst the latter only stated its general nature. If the provisional specification was studied in the first instance a general but loose and inaccurate idea of the real invention was likely to be obtained, and an incorrect conception might be thus formed, and if formed would probably lead to error. Turning, then, to the complete specification as it stood before it was amended, what was the invention really? The patentees claimed to have discovered a new system of distributing electricity for the production of light and power. The system consisted of a combination of the following particulars—first, an alternating current of high tension produced by an electro-dynamo machine; secondly, the passage of such a current through a number of electrical generators of a special construction; thirdly, the formation of such passage of induced currents, the quality and value of which depend only on the construction of the secondary coils of the electrical generators; fourthly, the utilisation of these induced currents for the production of light or motive power. The specification and drawings show that a main wire was to be used for the passage of the current produced by the electro-dynamo machine, that this main wire might be miles in length, and that the electrical generators were to be attached to this main wire where wanted. In the first instance, it was said that there might be an unlimited number of these generators. That expression has been amended and the word "unlimited" struck out. That amendment did not, in the opinion of their lordships, affect the validity of the patent. There might be as many electrical generators as in practice were wanted, and that was all that anyone would understand by the use of the word "unlimited" in connection with the rest of the specification. Having stated in general terms what the patentees' system or invention really was, it became necessary to ascertain what, according to the original specification, is the most essential element in it. That was the specially constructed electrical generators. It was impossible to read the complete specification as originally drawn without seeing that everything turned on those generators. The quality and value of the induced currents were said to depend only on the construction of the secondary coils, and they were specially claimed by the patentees in their third claim. It was also impossible to read the provisional specification without coming to the same conclusion. It was therefore necessary carefully to study these forms of generators. The electrical generators described in the specification and shown in the drawings were induction coils. But the patentees had described two forms of them—they did not say, and there was no reason to suppose it, that no other would do; nor did they point out what in particular was the essential feature of either of them—but the patentees had described two forms which had certain common features, and there was no reason to suppose that the forms described were not the best known to the patentees when they filed their specification. There was evidence that the forms described would produce the desired results, and there was no evidence to the contrary. Moreover, there was strong evidence that any competent workman could make induction coils which would produce the desired results by following the specification and drawings, and using such knowledge as he would himself possess. The patentees supposed a main wire fifty kilometres long, and a secondary generator (that is, induction coil) at every five hundred metres; but the size of the main wire was not stated. The first example of induction coil consisted first of a central coil of soft iron wire capable of being drawn out of or pushed into the hollow tube made by the wire coiled round it, and referred to generally. The word in the specification is "a wire" in the singular; but the Court understood that any competent workman or electrician would see that a bundle of wires, and not one wire, was meant, and the Court so read the specification. Secondly, it consisted of a copper wire of about 3mm. in diameter, perfectly insulated in three rows of super-posed coils round the core. This was the primary wire, and its length was not stated. A third element was the bobbins placed over the cylinder formed as above; and the fourth a cable wound round each of these bobbins, and composed of six copper wires of half a millimetre in diameter, each strand being insulated by means of paraffined cotton. This cable of six wires formed the secondary wire of the induction coil, and its length was not stated. The second example of an induction coil consisted, first, of a core like the above; secondly, of an insulated primary copper wire, four millimetres in diameter, surrounded by six cables, each composed of 12 insulated copper wires of half a millimetre in diameter. These cables formed the secondary wires, and were to be arranged parallel to and completely surrounding the primary wire, so as to form with it one cable. The proper lengths of the wires were not stated. The cable thus formed was rolled on a hollow cylinder of wood, say 50 centimetres long and six in diameter. Each layer of spirals was separated from the other by two cylindrical segments of iron, two millimetres thick and without contact, to avoid heating. The extremities of the six fine wire cables were united to a commutator, which allowed of their being moved either in tension or quality. It was apparent from those two descriptions that the patentees represent the cable formation of the secondary wires to be important, quite as important, in fact, as anything else they described; which, however, was admitted not to be the case. Having thus arrived at the nature of the invention and the mode of carrying it out, as described in the specification, let them now turn to the evidence given at the trial. Their lordships had studied the evidence with care, and had come to the following conclusions: First, although some of the specifications in earlier patents come very near to the patentees' invention, none of them quite come up to it. No one had previously hit on a combination of (1) an electrical dynamo machine producing alternating currents of high tension; (2) a long main wire; and (3) induction coils specially constructed placed along it at intervals for producing light and motion when required. The alleged anticipations all fall short of this. Their second conclusion was that the patentees' system was essentially the combination just mentioned, which was new and useful, and apart from the special construction of the induction coils; the system was indicated, as Sir William Thomson said, in the drawings to the provisional specification without the letter press. Thirdly, nothing really turned on the special construction of the secondary generators, on which the patentees unfortunately laid so much stress; they were not types of any class which had not all their special features. Fourthly, they considered that a competent person, having once seized the idea of the combination shown in the drawings, would see at once how to carry it into effect, and would without difficulty or further instruction select an induction coil suitable for his purpose without adopting either of the specially constructed coils, and without being told by the specification the lengths of the wires to be used, or the ratio which one of them must bear to the other in length, size, or weight. That, in the opinion of their lordships, was the true result of the evidence. Any competent electrician would see that a long main wire must, for economical reasons, be as small as circumstances would allow, that the tension of the current sent along such a wire must be high—far too high to bring into a lamp with safety—that this tension must be reduced, that induction coils could be made to reduce it, that the lengths and thicknesses of the wires would depend on the object to be attained, and could be ascertained from the law of tension—a formulæ given in Clerk Maxwell's book. The evidence, in their lorship's opinion, proved all that, and the state of knowledge was such as to supply the absence of instruction in the specification with reference to these details. The nature of the invention was "particularly described and ascertained," and two modes of carrying it into effect were sufficiently described to enable any competent electrician who seized the idea to give effect to it notwithstanding the want of detailed instructions. It was not necessary for the Court to decide whether the patentees could or could not have obtained a valid patent for their system apart from their specially constructed induction coils. Perhaps they might have done so. Unfortunately, that was not their intention as originally described. They have over-estimated the value of their specially-constructed generators, and have so drawn and altered their specifications as to have missed their mark. As already stated, their special form of generator was originally made an essential feature in their system. This was a grievous mistake. They have tried to correct it by amending their complete specification, but in doing so they have entirely changed their patent and the nature of their claim. To understand the effect of this amendment it is necessary to see what the patentees have done, and what they now claim by their amended specification to be the invention for which they have obtained their patent. The amended specification was vague and ambiguous on this very important point. If confined to a combination of dynamos giving alternate currents of high tension, with a main wire and one or two induction coils specially described, the patent will be of little or no use to the patentees; whereas, if construed more extensively, so as to include a combination of such a dynamo with any induction coil having the properties of the two described the patent would be of immense practical value, for the evidence showed that any coil which anyone would be likely to make would have such properties. The second of these two constructions was therefore obviously that which would be most beneficial to the patentees, and that was the construction which the patentees had laboured to maintain. The whole of their evidence was addressed to that. No serious attempt was made to show that there was any merit in the two specially described generators, except their movable iron wire cores, which almost all induction coils had in 1882. Their lordships were satisfied that no other construction was worth contending for, and it was, in their opinion, the true construction of the specification as amended. The specially-constructed generators were no longer claimed either separately or as essential parts of the combination; they were seen to have no particular value, and had been dropped accordingly. But this construction of the amended specification rendered the patent hopelessly bad in law, for (1) on this construction the invention is not the same as that described in the provisional specification, but an entirely different invention, and (2) on this construction the amendment of the complete specification has greatly extended the scope of the patent. As already shown, the essence of the invention, as described in the complete specification in its original shape and as set out in the provisional specification, lay in the use of a specially constructed electrical generator or combination which the patentees believed to be superior to all others, and, in fact, to have magical powers, and if they threw this over they so far departed from their invention as originally described as to render the patent they had obtained for it worthless and incapable of being supported. The law upon this point was perfectly well settled, and it was needless to refer to the authorities upon it. This view of the case rendered it unnecessary to consider whether the patent could be supported if it were construed narrowly and confined to a combination of an alternating dynamo with induction coils constructed like one of the two described in the specification. That point was not much argued. A decision in favour of the patentees would be of little use to them, and the patentees did not care which way it was decided, as they said they did not use that particular combination. That point, if it arose, would be full of difficulty, considering the evidence given at the trial; but having regard to the terms of the specification and the real contest between the parties, the Court did not think it called for decision. In their lordships' opinion the patent was bad, and the appeal must be dismissed with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *February* 23*rd*, 1889.

During the past fortnight the interest in electrical matters in this country has centred largely in the West. The Edison people, as I noted last week, have just held a highly successful Convention at Kansas City, and now the National Electric Light Association has been in Convention at Chicago. Both Conventions have been remarkably well attended, and have been like their predecessors in starting a hearty local interest in electrical matters. Kansas City, as one of the gateways of the South-West, was well chosen for the Edison Convention, and the gathering appears to have attracted a great deal of attention from the press in that section. If it did nothing else, the meeting served to advertise the new Edison plant in Kansas City, which is now nearly ready to go into operation, and which is reported to be one of the very best of the many fine Edison plants that have lately been installed. At Chicago special interest attaches to the Convention from the fact that the National Electric Light Association came into existence in that city four or five years ago in a very unpretentious fashion, and now revisits the scene of its birth a strong and influential body, full of life and vigour, and one that is capable, with judicious management, of doing incalculable good for the electric light and power industry in this country. It often happens that the two Conventions are held within a short time of each other, and sometimes in the same place. Thus we have the Chicago meeting following that of Kansas City, and it is said that both bodies will go to Niagara Falls next summer. But in spite of this there does not appear to be any material approach to an *entente cordiale* between the two organisations, although there are several electric light men who have probably membership in common, or could secure it if they wished. There can be no doubt that in some respects the Edison method of simply calling together those who are interested in the Edison light, and sitting with closed doors, has its advantages over the other method of bringing together a number of men representing conflicting interests, and often connected with rival plants in the same town, so that of necessity really vital questions are often avoided rather than discussed on the floor of the meeting. Moreover, the Edison Convention has the advantage in being composed of men who are actively engaged in the actual work of lighting, while on the other hand the National Association is largely composed of manufacturers of apparatus and dealers in supplies, so that matters are more apt to be viewed from their standpoint than from that of the man who has to produce current and sell it profitably for light and power. But putting these considerations aside, the National Association has achieved its success on the very ground that it is liberal and comprehensive of all electric lighting systems, as well as of all those in any way interested in their development, and its very catholicity of spirit in this respect has been one of the chief agencies in its growth and popularity.

As I have said, electrical interests in the West will undoubtedly be benefited by these methods of concentrating the public attention on them for a week or two. It is impossible for the daily papers in any community to give up their columns day after day to the discussion of the growth of electricity without arousing healthy and fruitful interest in the subject. The West, too, has always been particularly favourable ground for the reception of electrical ideas and novelties. In many towns and cities of the West practically the whole dependence for lighting has been on electrical apparatus, and in many others the current is largely used for power purposes as well. Some large isolated plants are also to be found in the West, and extremely good results are obtained with them. An example of what is done in this respect is furnished by the *Electrical World* this week, which published detailed descriptions and illustrations of the new Edison plant for 80,000 lamps in Chicago, and the fine new Thomson-Houston plant put in at St. Paul, Minn., for the local gas company. The *World* also contains another example in its article on the magnificent isolated plant of arc and incandescent lights in the big Pillsbury Flour Mills at Minneapolis. Some idea of the extent of these mills may be formed from the fact that one of them alone makes more flour than will feed New York and Brooklyn, and that the three together require 200 cars a day to bring the wheat to them and to take away the flour and refuse. The mills are driven by the water-power of the falls of St. Anthony, but have engines to fall back on in case the 135,000 horse-power there available should be overdrawn at any time by the numerous mills. The lighting plant includes Weston, Brush and Edison apparatus, and it is interesting to note that the current is used not only for lighting but for a number of other purposes. For example, there are 12 to 15 millwrights at work all the time, and they are provided with lamps and flexible cord connections to be inserted in the nearest lamp socket, so that light is available at any point. The lamps are used in the same way by the bolters to examine the bolting cloth, and by means of an ingenious little electric "furnace" the current is used in testing the quality of the flour. The ovens are heated by electricity, and the dougher, when he wants the ovens warm, just turns a switch throwing the current on, and in a few minutes the temperature is exactly what he wants, and is under perfect control. The current is also used to ring all the call bells at a saving of about £6 a month in battery material, and it operates fire alarm and other miscellaneous circuits. All that is needed to complete these ingenious utilisations of the current is that the heavy shafting that now requires so much attention and labour should be replaced by wires furnishing current to electric motors; and from the success already obtained in such work I believe it will not be long before these huge mills, as well as many others like them, will be driven by electric power.

Some idea of the popular curiosity and interest with regard to electric railways may be formed from the fact that the Boston *Herald*, in a recent Sunday edition, published the portraits of a large numbers of the drivers, or "motorneers," or whatever they may choose to call them, on the West End electric road in Boston. The paper also gives an interesting description of a trip taken by its reporter alongside one of these men, and of the various novel episodes that attended the journey to and from the car stables. Interviews with these men bring out the fact that they all prefer electric power very much to the old method of operating with horses. Not only is the Electric Motor Company a commercial society for the prevention of cruelty to brute beasts, but it appears to be equally humane in its work on behalf of the drivers. These men have no longer to stand in front of the car subjected to a hoof bombardment, with incessant jerks pulling their arms out, but can take things as quietly almost as if they were mere passengers. As one of them says, "It is out of sight and round the corner ahead of the old style. It is child's play compared with handling horses. Here you see I have over seven horses at my command. All that I need do to hitch them on or turn them off is to turn this pointer to or away from me. Each of these raised bars indicates a horse-power except the first, which stands for one and a-half. That small power is sufficient for a good pace on the level, and if we stop on the curve it will carry us around easily. In coming up a steep incline or a long hill we put on more power. This is in every way ahead of horses. The current is more manageable; we can stop quicker and start easier; no backing horses, no tired and played out nags to urge up hill on a sultry dog day. We can reverse our motion by simply turning the pointer; in fact, I could not conceive of anything more powerful, more tractable, and more easily managed than the electric current. I have driven horses for twenty-five years and know something about the work. I would not go back to driving horses again for anything." Such testimony as this from the men themselves speaks volumes for the advance that has been made by electricity in the development of urban transportation facilities, and I need hardly say that the public are just as enthusiastic as the drivers. What the company thinks of the results may be inferred from the reports which reach us of the intention to equip in and around Boston as soon as possible over 200 miles of the electric overhead system. How does that strike you for development, and not in a new Western town but in a Conser

Digitized by Google

vative old place like Boston, which has as many obstructives among its population as any city of its size in Europe?

It appears by the reports from Boston that the market value of Bell Telephone Stock has advanced there this week owing to a report that the Patent Office has just taken action with regard to an application made by Mr. Emile Berliner, of Washington, relating to improvements in the telephone transmitter, and that the application in question will have the practical effect of extending the Bell monopoly, which would otherwise expire in four or five years It is alleged that this application is the one that was made by Mr. Berliner as far back as April, 1877, and that its issue has been delayed by collusive proceedings until now, an interference with Edison being utilised for the purpose, both applications being owned by the Bell Company. There has been talk from time to time in the past as to the pendency of this application, and the newspapers now take the matter up as illustrative of the means used to prolong profitable monopolies by a skilful manipulation of Patent Office methods. It has before been brought to the attention of the public by the Patent Commissioners that applications have been in the office nine or ten years in which the Patent Office was powerless to compel speedier or earlier action on the part of applicants, and it is claimed that this is one of such instances. Probably we shall soon know a little more about this. There is no doubt as to the favourable action on the patent by the Board of Examiners, but it is denied by the Bell Company that it is a bottom patent to be used for any such purpose as that which is now being subjected to denunciatory rhetoric on the part of the newspapers.

The American Institute of Electrical Engineers had an interesting meeting last week, when two valuable Papers were presented. One was by Lieut. F. J. Patten, U.S.A., on his new system of multiplex telegraphy, in which he employs as synchronous devices machines which are in themselves not isochronous, and the action of which is entirely dependent one upon the other. Hence the system differs materially from others in which synchronism is sought to be obtained by maintaining two mechanisms in unison by correcting any difference that might occur in their normal rates of independent operation. Lieut. Patten has devised a quantity of ingenious appliances for his purpose, and spoke in his Paper of his work for not only in connection with utilising the alternating current his purpose, but in employing a machine the armature which has two coils in series connection, but wound with their poles at right angles to each other. This armature being placed in a single field he had supposed would move at only half the speed of the first machine with a single armature; but, on the contrary, the synchronism was perfect, the motion was continuous in direction, and it has never been known to reverse. I need not, and, in fact, could not, go into the many details of Lieut. Patten's complicated and highly ingenious system, but I may say it was very favourably received, and in these days of machine telegraphy it seems likely to meet with a cordial reception on the part of the economising companies. The other Paper presented was one in discussion of Mr. Acheson's recent interesting Paper on lightning arresters, and the photographic study of self-induction, by Mr. J. Stanford Brown and Mr. T. C. Child, tending to throw a little doubt on the results which were arrived at by Mr. Acheson with so much care and painstaking.

NOTES FROM GERMANY.

(FROM OUR CORRESPONDENT.)

BERLIN, *Feb.* 25, 1889.

In Nuremberg the railway station, a *chef d'œuvre* of Gothic architecture, has been provided with the electric light. The passenger hall and platforms are lighted up by thirty 5-ampere lamps and four lamps of 10 amperes each, in addition to which the square before the station, the engine rooms, track ways, store houses and loading tracks, and the road along the goods platform, have been taken into the electric light area. The three dynamos used give 200 amperes at 120 volts, and are driven by three 32 horse-power non-condensing engines. The steam is furnished by two boilers on the Sinclair system of 59·5 square metres heating surface each. The insulation resistance of the installation was found to be 35,000 ohms, which corresponds to 120,000 $\frac{E}{C}$. This high value has its ground in the almost exclusive use of arc lamps. As to insulation resistance Prof. Waltenhofen, of Vienna, wants to read 10,000 $\frac{E}{C}$, whilst the *Elektrotechnischer Verein* of this town accepted the formula 5,000 $\frac{E}{C}$. Mr. Uppenborn gives his opinion in the *Centralblatt für Elektrotechnik*, and it is the same as Waltenhofen's.

For the town of Elberfeld two central stations have been planned, the district being a very long one. The northern station has been erected, and is working 4,300 lamps. The boiler house contains three boilers, with space for three more. There are four compound engines of 170 horse-power, each driving two dynamos with an output of 390 amperes at 121 volts. Twenty cables run from the station to the different quarters of the town, the three-wire system being used. The estimate for 10,000 lamps was 750,000 marks, of which sum so far 500,000 marks are spent.

The left side of the Main at Frankfort will be within a week or two provided with a small transformer plant. The complete plant was some weeks ago shown to the members of Ingenieur Verein of Cologne in full work at the works of the Helios Company. The result of these trials shows that, contrary to Prof. Rühlmann's assertion, properly-built alternating-current dynamos may be coupled in parallel by simple manipulation, and that it is possible to use alternating currents for the purposes of electrical transmission of power.

Messrs. Fritsche and Pischon's new wheel armature dynamo is said to be a great advance in the construction of dynamos. The new dynamo is a variety of the multipolar disc machine, in which, by a peculiar coupling of single rods, the winding of the armature is solely limited to the convex surface without using the plane faces. The armature is built up without a core, without cotton insulation, without copper, and without a special collector construction. It is built up of a lattice-work of wrought iron rods, which are separated by air spaces. The special winding does away with a complicated collector, the rods of the winding being prolonged as segments of the commutator. The smallest of these dynamos supplies 50 16 candle-power lamps, yielding 50 amperes and 65 volts at 240 revolutions per minute, or supplies 55 lamps and gives 25 amperes and 110 volts at 270 revolutions. The largest of them gives 3,200 amperes and 65 volts, or 7,600 amperes and 110 volts at 70 and 82 revolutions per minute respectively. These dynamos, therefore, supply 3,500 65-volt lamps, or 3,200 110-volt lamps.

Herr Zöpke, of Berlin, states that in the course of his business he has heard very different opinions about the Edison lamps sold by him. Some of his customers could not sufficiently praise the durability of the lamps, while others assert that the average life of a lamp is no more than a few hundred hours. It is well known that if the E.M.F. at the terminals is 100 volts, 95-volt lamps that burn 10 hours, 100-volt lamps that burn 100 hours, and 105-volt lamps that burn 250 hours, show the same amount of carbon deposit—that is, show the same blackening of their glasses. Besides, the 95-volt lamps show a brownish shine, originating from a small deposit of copper. From these deposits conclusions may be drawn as to the wear of these lamps, and if a rapid consumption is observed, an inspection of the whole plant, and especially of the voltmeter, is urgently necessary. Herr Zöpke therefore offers a prize of 1,000 marks, to be awarded by the Berlin Technical High School, for the solution of the following problems:—(1) Construct a constant voltmeter, not depending upon changes in temperature or structure of material; or, if this is impossible (2), construct a recording apparatus, as simple as possible, to control the voltmeter, which shall exactly register the time during which a too high voltage has been used.

CORRESPONDENCE.

THE PERIODICITY OF EARTH-CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Perhaps the following remarks may be of interest to your readers:—

On the Batavia-Singapore cable running N.W. and S.E., the diurnal earth-currents passing through it are very slight; and as I have been present at every one of the thirty-nine tests I quote, I have been able to make some rather interesting observations of the *annual* earth-currents, of the existence of which I was previously unaware.

When testing the copper resistance of a cable with the Wheatstone Bridge, always bearing in mind the fact that when there is a slight fault in a cable (which has been the case with ours since 30th August, 1887) the copper readings tend to be higher than the zinc, a little thought will verify the rule that

Digitized by Google

when the zinc readings are higher than the copper a negative current is flowing from the cable, and when the copper readings are higher than the zinc the opposite is the case.

Hence, the direction of the earth-current can always be observed from the zinc and copper readings when testing the copper resistance if the cable is nearly perfect. When the cable is faulty, and the zinc readings exceed the copper, we are still sure a negative current is flowing from the cable. The following readings show that the earth-currents between Singapore and Batavia run for about six months in one direction, and then for six months in an opposite direction. Can they depend on the vernal and autumnal equinoxes?

(*A*) Tested with false zero.

N.B.—A slight fault was discovered in the cable on August 30th, 1887, which has not yet developed itself sufficiently to be localised.

On the 22nd November, 1887, the 19th December, 1887, and the 14th May, 1888, the earth-currents, when measured independently, were of opposite name to what, from the copper resistance readings, one would have expected them to be. I cannot understand this. Perhaps there was some mistake.—Yours, &c.,

A. H. BENGOUGH.

The Eastern Extension Telegraph Co.,
Batavia, 19th December, 1888.

THE INSULATION RESISTANCE OF INSTALLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think that Prof. Jamieson was rather unnecessarily severe in his remarks contained in *The Electrician* of the 22nd inst. on Dr. Waltenhofen's tests of the new Burg Theatre Installation. The Uppenborn method may possibly be old, but I cannot remember to have seen it described in any English Paper before what is practically a similar method was described in the article of M. Picou, which appeared in the *Electrical Review*, November 23rd, 1888. Certainly Dr. Waltenhofen first became acquainted with this method through Uppenborn's *Centralblatt für Elektrotechnik*, No. 22, of the year 1888, and this source only; he therefore was, I think, justified in speaking of it as he did.

At the meeting of the Committee of the Vienna "Electrotechnischer Verein," appointed to frame fire risk rules, Mr. Ross never claimed that the formula proposed by him was original. He stated clearly that he remembered to have read that a somewhat similar formula had been suggested, but could not say where he had seen it. It is not therefore surprising that this formula is locally called the "Ross" formula, and this has been rendered literally in translating Dr. Waltenhofen's Paper.

I am very glad that Prof. Jamieson appreciates generally the methods Dr. Waltenhofen adopted, and he cannot be otherwise than satisfied with the results obtained. The final measurements were not made after lamps, motors, &c. (please what does this "&c." mean?) were removed, as allowed by the rules of the Society of Telegraph-Engineers, but with *all* lamps, holders, switches, fuses, &c., connected. The *whole* installation was first lighted up and inspected, then the accumulators were disconnected as quickly as possible, and the measurements made at once.

Prof. Jamieson would not either have considered the amount of trouble and detail superfluous had he been acquainted with the whole circumstances of the case. I cannot, however, occupy your valuable space with going into them fully here, but shall be pleased to give Prof. Jamieson such privately if they are of interest to him.—Yours, &c.

T. W. W. MELHUISH, Assoc. M. Inst. C.E.

1, Schenkenstrasse 10, Vienna, February 28, 1889.

ENAMEL AS AN INSULATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have recently made an invention which I consider of the greatest value to the electrical trade, and I shall be glad to publicly give them the benefit of my invention.

I find that such articles as the cores of electro-magnets, bobbins, and, I believe, even wire, can be coated with enamel or similar vitreous substance, and that this acts as a splendid insulator and protection for the wire to be wound thereon. It can also be used for the inside coating of iron tubes for the carrying of underground wires, and I think that many of your readers will find this of the greatest value.—Yours, &c.,

London, S.W., 2nd March, 1889. F. H.

GLOBULAR LIGHTNING.

TO THE EDITOR OF THE ELECTRICIAN.

[Translation.]

SIR: In spite of Mr. Sydney Evershed's jokes I can assure him that some fifteen years ago I saw a kind of fireball drop from some clouds which were very near to the ground, there being at the time a storm, accompanied by heavy rain. I say a kind of fireball because there was all around me brilliant red light. It fell in a corn-field, and seemed to crush the wheat as it slowly rolled along. All this lasted about a second; a violent explosion then ensued, and the fireball disappeared, without any other zig-zag lightning. Having at that time of my life but vaguely heard of globular lightning I could not believe my eyes; nevertheless, I did actually see the phenomenon.—Yours, &c.,

J. VAN MOORSEL.

106, Boulevard du Midi, Brussels.

ELECTRIC LIGHTING COMPANIES AT KENSINGTON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have perused Mr. R. S. Erskine's letter in your last issue, and I regret to hear that he considers that his company is likely to suffer from there being two electric light stations in Kensington—viz., that of his company, known as the "Kensington Court," and that of my company, known as the "Kensington Central."

I take the opportunity of pointing out to you the following considerations which bear upon this question:—

1. The Vestry of Kensington has mapped out the parish of Kensington, and very carefully allocated certain districts to

Digitized by Google

certain companies, so that it is impossible for my company to carry its mains into the district served by the Kensington Court Company, and it is equally impossible for the Kensington Court Company to bring its mains into the district allotted to us; so that I cannot see where confusion can arise.

2. In the event of customers in the Kensington Court district applying to us it is clearly out of our power to supply them, and all we can do is to refer them to Mr. Erskine's company; and if he adopts the same procedure with customers applying to his company for light in our district we can mutually work Kensington without trespassing upon one another's business.

3. Mr. Erskine points out that the Board of Trade have not yet sanctioned the license which is before them in favour of our company, and then he complains that we have up to the present time done no lighting in Kensington. No one is better aware than he is himself that until the Board of Trade's sanction is obtained no extensive lighting can be done, and that in the meantime we are limited to supplying the streets belonging to private persons where we have laid the mains without having to apply to the Board of Trade for its consent.

4. Mr. Erskine again draws attention to the fact that my company claims to have erected "the first station which has been completed in the metropolis for the accomplishment of house-to-house electric lighting throughout an extended area by means of underground mains." My managing director, Mr. Robert Hammond, has pointed out to Mr. Erskine, in the *Times* and elsewhere, that Mr. Erskine's intimation that his company has done satisfactory work over a small area by means of underground mains is no refutation of the claim made by the House-to-House Electric Light Supply Company (Limited) that its station at Kensington is the first station completed in the metropolis designed to cope with electric lighting over an *extended area* by means of *underground mains*. The fact that Mr. Erskine's company has laid down a second station at Knightsbridge within a short distance of the first station proves that from the first station his company is not able to cope with an extended area.

5. Mr. Erskine is well aware by what authority my company is supplying a portion of Kensington, and he is also well aware that the Vestry have sanctioned the application of my company to the Board of Trade for a Provisional Order covering a much more extended area than the one we are at present dealing with.

6. The station of my company has been called the Kensington Central Station, because it has been erected within the parish of Kensington, and is designed to supply a considerable portion of that parish with the electric light, and though we started by calling it the West Brompton Station, we found that name did not sufficiently appeal to the householders of Kensington, to whom we were offering the light.

Apologising for the space taken up by this letter, I am,
Yours, &c., H. St. John Winkworth,
Secretary The House-to-House Electric Light Supply Company (Limited),

117, Bishopsgate-street Within, London, March 5th, 1889.

[As we are unable to see what useful purpose is served by a correspondence of this nature, we must beg that it now cease. —Ed. *E.*]

COMPANIES' MEETINGS & REPORTS.

Brighton and Hove Electric Light Company.

The annual meeting of the Brighton and Hove Electric Light Company (Limited) was held last week. The report was printed in our last issue.

In the absence of the Chairman of the Company (Mr. Robert Hammond), Mr. PHILIP ARDERNE LATHAM, one of the Directors, took the chair. He said he had much pleasure in laying before the shareholders such a satisfactory report and balance-sheet, showing that, after debiting the revenue account with the necessary outlays for keeping the plant in thorough repair, the Directors were able to write off 5 per cent. for depreciation of plant and pay a dividend of 5 per cent., which dividend would have been much larger if the Directors had not decided during the past year to run the machinery day and night, in deference to a very generally expressed wish on the part of the customers. The new plant has given very great satisfaction to the consumers, who were able in private houses to turn on the light at any hour of the night or early morning, and thereby found it a great convenience. It, however, kept the works in operation during the whole of the twenty-four hours, and entailed a great increase in wages and other charges, and he considered that it was a matter of great congratulation that in spite of these extra charges the 5 per cent. dividend which was declared twelve months ago had been maintained for another year. During the past year the Board of Trade's electrical adviser had visited Brighton and inspected the installation, and in consequence the Company had received from the Board of Trade a request that the Company should, without delay, apply for Parliamentary powers. In accordance with this intimation the Company had applied for Parliamentary powers, but he was sorry to say up to the present time this application had not received favour from either the Brighton Corporation or the Hove Commission. He considered this a great pity, because the Company would prefer to work harmoniously with the Brighton Corporation and the Hove Commission, instead of obtaining powers over their heads; for he would point out that the Electric Lighting Act gave to the Board of Trade power of granting a Provisional Order in spite of the opposition of a Corporation in cases where they considered that the opposition was of an immaterial character. He was, however, in hopes that a *modus operandi* could be arranged by which the Company could work in friendly accord with both the local bodies. Their one desire in applying for statutory powers was to abolish the overhead wire system and run mains underground, but the shareholders would understand that it was impossible to do so without obtaining Parliamentary powers. As soon as the mains were run underground the Company would be enabled to greatly improve its service by putting in larger mains and getting a better regulation of the light. The shareholders of the Company had recently met and sanctioned the raising of the nominal capital of the Company from £25,000 to £100,000, and the change of the name from the Brighton Electric Light Company, Limited, to the Brighton and Hove Electric Light Company (Limited). When the Parliamentary powers had been obtained, the shareholders would be called together and consulted with regard to further plans for the extension of the Company's operations. He might mention, too, that the Directors had in contemplation the immediate erection of a central station on the confines of Hove with a plant sufficient to supply 12,000 incandescent lamps somewhat upon the scale of the station which had recently been erected by a kindred company in London. He had much pleasure in moving that the report of the Directors and the accounts for the year ended December 30th, 1888, be received.

This resolution was seconded by Mr. ARTHUR WRIGHT, and carried unanimously.

It was then proposed and carried unanimously that the retiring Directors, Mr. Robert Hammond (the Chairman of the Company) and Mr. Arthur Wright, Managing Director, should be re-elected.

The CHAIRMAN then moved that the Auditors of the Company for the ensuing year should be Messrs. Ball, Baker, Rowe and Co.

This was seconded by Mr. JERRARD, and carried unanimously.

It was proposed by the Rev. H. REVELL REYNOLDS, seconded by Mr. JOSEPH CASH, and carried unanimously, that the Directors' fees for the coming year should be fixed at £200, this sum to be divided among the Directors as they think fit.

A vote of thanks to the Chairman terminated the proceedings.

The Anglo-American Brush Electric Light Corporation (Limited).

Report of the Directors to be submitted to the shareholders at the eighth ordinary general meeting, to be held at the Cannon-street Hotel, London, E.C. (Alexandria Hall), on Wednesday, March 13, 1889, at 12 o'clock noon :—

2. In view of the fact that, since the date of the last general meeting, two interim reports have been issued to the shareholders, the Directors consider that the usual *résumé* of the year's work admits of some curtailment in this instance, and they now confine themselves chiefly to a statement of the present position of the Corporation, and to an explanation of the yearly accounts.

3. In the special report of the 18th July last the Directors explained in some detail the circumstances attending the litigation with the Edison and Swan United Electric Company in regard to incandescence lamp patents, and reported the decision which Mr. Justice Kay had given in favour of the Corporation on the Edison patent.

4. The interim report of the 3rd October last contained a general statement of the position and prospects of the Corporation at that time, and of the work accomplished during the first nine months of the year.

5. The Directors are glad to be able to announce that the expressions of confidence with regard to the future of electrical industry contained in their previous reports are fully borne out by the progress effected during the past year. An extensive and more genuine demand for electric light and power has made itself evident, to the great benefit of the industry generally, and to the Corporation individually, as will be seen from the satisfactory character of the accounts now presented of the Corporation's affairs.

6. It is now generally admitted that the amendment of the Electric Lighting Act of 1882, which extends more favourable terms to the electrical contractors, and thus justifies the investment of capital in central installations for the supply of electric current, will produce highly beneficial results. As a matter of fact, although only a few months have elapsed since the Amendment Bill introduced by Lord Thurlow became law, considerable impetus has already been given to the business, and there is now much greater activity in all branches of the industry.

7. The improvement in the general position of the Corporation which has followed upon the revival of business in this direction is, however, not yet exhibited in the accounts now submitted, as the orders which have been received in connection with the supply and erection of plant for

Digitized by Google

central stations are still in progress. The marked improvement which is seen from the accounts is due almost entirely to the growth of the ordinary business.

8. There are also indications that the amendment of the Electric Lighting Act will have a salutary effect in other directions, and by inspiring renewed confidence, tend to establish a better understanding among the various electrical manufacturers and contractors. United action where common interests are involved is greatly to be desired, and a diminution of the unhealthy competition which has prevailed during the recent depression is necessary to enhance the profits of the business. The formation of an electrical trades section of the London Chamber of Commerce, affording as it does opportunities to the principals in the various electrical firms for discussing common interests, is a step in these directions.

9. The result of the past year's work is, under all the circumstances, highly satisfactory. As compared with the previous year, the volume of business shows an increase of about 38 per cent. and the gross profit an increase of 70 per cent., while the standing charges have increased by only about 7 per cent.

10. The net balance of profit, after providing for depreciation and bad debts, is £12,885. 4s. 9d., which is equal to more than 5 per cent. upon the entire capital of the Corporation.

11. It is to be remarked that this profit has been earned almost entirely upon the ordinary transactions of the year, and does not include the profit accruing from the central station work now in hand, and that there are still other important fields from which the Corporation are able to derive revenues. The shareholders will therefore recognise that the business of the Corporation is now not only established on a reliable profit-earning basis, but that very sanguine expectations with regard to the future development of the business and payment of dividends are justified.

12. The contracts carried out by the Corporation during the year include important work in almost every department of the electrical industry.

13. The lighting of the Melbourne Centennial Exhibition, which proved eminently successful, and comprised the largest installation of the kind yet erected, was carried out almost entirely by means of the Corporation's apparatus, supplied at very short notice to the Australasian Electric Light, Power and Storage Company.

14. The contract secured for the arc lighting of the main building and grounds of the Glasgow Exhibition of 1888 was carried out to the thorough satisfaction of the Executive Committee, as will be seen from the following letter received from Sir W. Thomson :—"As Chairman of the Lighting Committee of this Exhibition I have much pleasure in intimating to you my entire satisfaction with the manner in which your contract was carried out. During the entire period the 520 arc lamps installed by you have worked with the greatest regularity and steadiness."

15. The illuminated fountain installation effected by the Corporation at the Barcelona Exhibition formed one of the most attractive features of the Exhibition, and was universally described as far surpassing all previous similar undertakings. This contract met with the entire approval of the Exhibition authorities, who have given the Corporation their highest award of a gold medal.

16. The Corporation have also been awarded a diploma in respect of their contract for lighting part of the Brussels Exhibition.

17. Amongst the installations on ships completed by the Corporation during the year may be particularly mentioned those on board the Castle Mail steamers—"Rosslyn Castle," "Hawarden Castle," and "Norham Castle."

18. Numerous installations have been carried out in private residences, factories, shops, offices, theatres, and other premises throughout the United Kingdom and abroad, and particular reference may be made to the completion of an important incandescent installation of 1,000 lights at Blenheim Palace for His Grace the Duke of Marlborough, and also to the lighting of Professor Piazzi Smythe's residence at Ripon.

19. The negotiations with the Honourable Commissioners of Sewers for lighting the City of London have been continued ; and it is confidently expected that at an early date specifications will be issued and tenders invited for lighting various sections of the City, for which the Corporation will be in a position to submit a proposal with good prospect of success.

20. The advance in the different technical branches has been of a very marked character, and highly-important results have been achieved, notably the perfection of the alternating-current system of distribution, which enables electric current to be supplied economically over large areas without any risk of danger to the public. The Corporation have designed a complete alternating-current system which is now perfect in every detail, and has been in successful operation during the past year. This apparatus has met with great favour since its introduction, and is now being manufactured on a large scale.

21. The Victoria dynamo machine for running incandescent and arc lamps in parallel has been improved in design and mechanical construction, and is generally recognised as one of the most efficient machines for the purpose in the market. This dynamo has been found to lend itself admirably for use in connection with direct driving engines at slow speeds for installation on shipboard, and has been manufactured in large numbers for this application. The special engines supplied by the Corporation from the designs of their superintending engineer, Mr. Raworth, meet with a ready sale, and constitute an important feature of the business.

22. The Corporation's trade in incandescent lamps has been considerably extended, and their Victoria lamps have secured a wide reputation for durability and economy.

23. When the Cheesborough patent was upheld by Mr. Justice Kay, in the recent action of Edison and Swan *versus* Holland and Others, the Corporation at once devoted attention to the production of a lamp in which the Cheesborough process of flashing could be dispensed with, and their efforts were so successful that the present form of Victoria lamp ranks as one of the most efficient in the market.

24. The Directors are glad to be able to state that the action referred to in the last annual report, which the Corporation instituted in 1887 against the Orient Steamship Company, who were using dynamo machines made by Messrs. King, Brown and Co., of Edinburgh, in infringement of the Brush patent for compound-winding, was decided wholly in favour of the Corporation by Mr. Justice Chitty, in December last, and the Corporation were granted a certificate of validity of the patent, costs and inquiry as to damages. Meanwhile Messrs. King, Brown and Co. have brought an action in Scotland for the revocation of the patent, and this case is now before the Court.

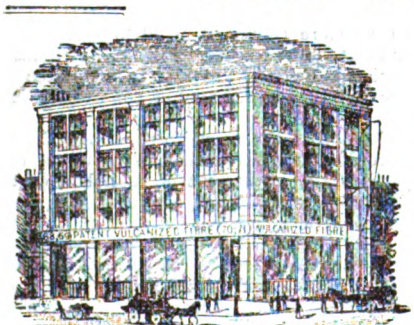
25. With the above exception every dynamo manufacturer of importance in the country has recognised the Corporation's claim, and the royalties now received constitute an important source of revenue. In this matter the policy of the Directors has been, while not harassing the trade or interfering with the growth of the industry, to protect the interests of the shareholders by charging a small royalty for the use by others of the Corporation's patent. The Directors, however, have no alternative but to resort to legal procedure when the usual commercial methods of protecting the Corporation's rights and of enforcing their just claims fail.

26. The action of the Edison-Swan Company against the Corporation for alleged infringement of the Edison patent in the manufacture of Victoria incandescent lamps is now under appeal to the House of Lords, the Court of Appeal, which had previously decided in favour of the Edison patent in the case of "Edison and Swan Company *v.* Woodhouse and Rawson," having recently reversed the decision which Mr. Justice Kay gave after a most exhaustive hearing extending over 22 days. In view of the fact that the House of Lords will not be bound by the decision of the Court of Appeal in the Woodhouse and Rawson case, and that the issue to be raised will in many respects be a new one, the Directors are advised that there is every prospect of the decision of Mr. Justice Kay in favour of the Corporation being sustained.

27. The Directors deeply regret the existence of this litigation, which is not only costly but is a very great disturbance to the proper conduct and development of the ordinary business. Litigation is, however, not always avoidable, and that relative to incandescent lamp patents has been rendered necessary by the action of the Edison-Swan United Electric Light Company. That company and the Corporation both hold patents for the manufacture of incandescent lamps, and it has always been the earnest desire and endeavour of your Directors to respect the interests of the two companies and of the industry generally by effecting a settlement equitable and honourable to all parties. In this effort, however, they have not as yet been successful, and have had no recourse but, in the interest of the shareholders, to defend to the utmost the action instituted by the Edison-Swan Company.

28. The Corporation have much to gain in the future by freedom from interference in their business as manufacturers of incandescent lamps under the various patents they hold, but unlike the Edison and Swan Company they do not rely for their revenue mainly upon the manufacture of these

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

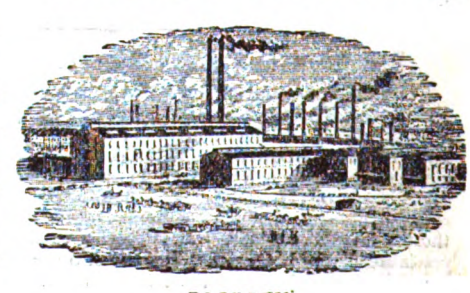
The **FLEXIBLE** is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The **HARD** is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and **is a good Insulator.**

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

Digitized by Google

lamps, inasmuch as the Corporation's trade in these articles at present amounts to scarcely 10 per cent. of the total volume of their business.

29. The capital account shows an increase of £4,640, which arises out of the issue, under the resolution passed at the general meeting in February, 1887, of 1,160 new shares.

30. The increase in the patents, development, and goodwill account of £1,749. 1s. 10d. is due to development of new inventions, and to the usual annual payments for maintenance of existing patents.

31. The profit and loss accounts includes a satisfactory profit derived from the Austro-Hungarian branches. This new department of the business has, during the past year, developed in every way satisfactorily, and bids fair to prove an important source of income in the future. The central lighting stations worked by the Corporation are now also yielding good profits.

32. The Directors consider the present a fitting opportunity for taking a general survey of the advance made during the five years which have elapsed since the reduction of capital in 1884, and with this view they submit a diagram showing the fluctuations during that period in the volume of the business, the general charges or expenses of management, and the gross profits.

33. To facilitate comparisons between one year and another, the actual figures are shown on the diagram in percentages, the figures for the year 1883 being taken as represented by 100. It will be seen that the volume of business in 1888 is to that of 1883 as 307 is to 100, showing an advance in the five years of upwards of 200 per cent., and while the gross profits have increased in the ratio of 100 to 342·9, or over 242 per cent., the standing charges have *fallen* in a ratio of from 1 0 to 65.

34. The above figures do not take cognisance of the business effected through the Continental branches. If this be added, as shown in the diagram by means of dotted lines, it will be seen that the advance of the Corporation's business is even more satisfactory, notwithstanding that the standing charges are relatively higher on the Continent than in England, which is due to the fact that the business carried on there by the Corporation is still young ; and it is probable that a much larger amount of trade could be effected without any material increase in the expenses of management.

35. The Directors think it will be recognised by the shareholders not only that the affairs of the Corporation have, during these five years, been conducted with energy and economy, but that, having regard to the hitherto undeveloped condition of the industry, and consequent difficulty and expense of working up a new business, the results must be considered as highly satisfactory and encouraging.

36. With regard to the prospects for the current year, the Directors have every confidence in a still further improvement, the orders during the first two months of this year being more than double the orders received during the corresponding period of any previous year.

37. The Directors who retire this year by rotation are Lord Thurlow and Colonel Steuart, who, being eligible, offer themselves for re-election. Messrs. Cooper Brothers and Company, the auditors, also retire and offer themselves for re-election.

NEW COMPANIES REGISTERED.

RAILWAY AUTOMATIC ELECTRIC LIGHT SYNDICATE (LIMITED).—This syndicate was registered on the 26th ult., with a capital of £10,000, in £25 shares, to produce and supply electric light, and for such purposes to adopt an agreement on the 14th ult., between D. H. Davies and John Tourtel of the first part, James Ernest Spagnoletti and Joseph Crookes of the second part, and W. H. England of the third part.

GREAT MARLOW WATER COMPANY (LIMITED).—This company was registered on the 25th ult., with a capital of £16,000 in £10 shares, to supply the town and neighbourhood of Great Marlow with water, gas, and electricity. Registered without special articles.

NOTTINGHAM ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This company was registered on the 27th ult., with a capital of £100,000, in £10 shares, 100 being founders' shares, to carry on at Nottingham the business of an electric light and power company. The number of directors is not to be less than 3 nor more than 9 ; the subscribers are to appoint the first ; qualification, 25 shares, or £250 stock ; remuneration, £400 per annum and 10 per cent. of the annual net profits, after providing for 7 per cent. dividend, to be divided as they may determine.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 1st, 1889, amounted to £5,327.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of February was 4,151, estimated to produce £3,200, against 4,535 messages, producing £3,666 in the corresponding month of last year. The traffic receipts for the month of November, estimated at £3,100, realised £3,107.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February are estimated at £2,008, as against £1,858 in the corresponding period of last year. The Board have, upon the audited accounts for the half year ended 31st December last being submitted to them, decided to recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend at the rate of 4 per cent. per annum on the Ordinary shares (free of income-tax), making, with the previous distribution, a divi- at the rate of 4½ per cent. for the year 1888 on the Ordinary shares, against 4 per cent. in 1887, and to carry forward £723. 5s. 3d. to next account.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company are as follows :—February, 1889, £19,600 ; January 1st to February 28th, 1889, £42,000 ; corresponding months, 1888, £41,600 ; corresponding months, 1887, £39,600.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February were £54,611, as compared with £51,261 for the same period last year, or an increase of £3,350.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February were £37,584, as against £38,795 for the same period last year.

THE NEUCHÂTEL TELEGRAPH WORKS.—The important telegraph and electrical apparatus works at Neuchâtel, which have up to the present been under the management of Dr. Hipp will in future be carried on by MM. Peyer and Favarger ; but Dr. Hipp will continue to render technical assistance.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this company for the month ended 28th February, 1889, amounted to £5,900.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 1st, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,467.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts for the half-month ended February 28th, 1889, were £2,696, against £3,201 for the corresponding period last year. November receipts, estimated at £5,203, realised £5,238.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 565.—Vol. XXII. FRIDAY, MARCH 15, 1889. Price Fourpence.

NOTES.

Dr. Lodge's Friday evening lecture "On the Discharge of a Leyden Jar," at the Royal Institution, attracted a large and distinguished audience, and was listened to with marked enthusiasm. The lecturer succeeded admirably well in the somewhat difficult task of handling his subject so as to interest both the scientific and the *dilettanti* elements of which a Royal Institution audience is made up. There is no need to attempt a description of the lecture here, since it is printed verbatim in the present issue. We may, however, remark that the experiment of lowering the frequency of oscillation until the discharge gives rise to a musical tone of definite pitch was markedly successful. It is done simply by increasing at once the capacity of the condensers and the self-induction of the circuit; the experiment may very easily be repeated by anyone who has the necessary apparatus at hand. The self-induction must, however, be obtained from a solenoid without iron, for even at the comparatively moderate frequency of 1,000 per second the effect of iron, however much laminated, is rather to diminish than to increase the inductance. The "musical spark" will no doubt form a favourite lecture experiment in future.

Whilst Dr. Lodge was illustrating the effect of increasing the length of the discharging circuit in exaggerating the length and noise of the spark, some excitement was caused amongst the audience by the discovery that electric discharges of a vigorous character were taking place at various points upon the walls of the room. It happens that the Theatre of the Royal Institution is hung with wall-paper having a gilt oak-leaf pattern, and thus it forms a sort of "spangled-pane." It is probable that the electric radiations, on being reflected from the walls, gave rise to secondary disturbances, which became visible as described. When the lights were turned down the phenomenon was very brilliant.

In the library of the Royal Institution an experiment recently discovered by Dr. Lodge, and closely akin to the famous Hertz phenomena, was exhibited. This was the excitation of minute but easily visible discharges in a circuit having a suitable time-constant when placed anywhere in the neighbourhood of a Wimshurst machine in action. When the time-constants of the two circuits are approximately equal, the successive impulses accumulate in the secondary circuit until at last the dielectric breaks down in the form of a visible discharge. That this is a radiation effect as distinguished from ordinary induction was made evident by *increasing* the self-induction of the secondary. This had the effect of suppressing the discharge altogether, whereas any effect of ordinary induction would have been of course augmented.

In an important Paper by Prof. J. J. Thomson, published in the last number of the *Proc.* Roy. Soc., it is shown that this very experiment affords a crucial test of the truth of Maxwell's theory, as against the modification introduced by Helmholtz. According to the latter view (in which the ether is assumed to possess a slight degree of compressibility) it is now shown by Thomson that in a circuit exactly similar to that used by Lodge in this experiment the time of vibration would be independent of the capacities of the ends. But Dr. Lodge, though apparently unaware of Prof. Thomson's demonstration, actually showed that when the self-induction of the circuit was changed the resonance effect could be restored by a suitable change in the size of the discs on which the wire terminated. This experiment, therefore, affords, in the words of Prof. Thomson, "exceedingly strong testimony in favour of the truth of Maxwell's theory, at any rate for conductors."

At the Physical Society on Saturday, Dr. Lodge did not get time to go over the entire programme which had been arranged, and he therefore virtually confined himself to a repetition of the experiments of the previous evening with a development of the theory. The beautiful phenomenon of the rotation of the plane of polarisation in alternate directions by the Leyden jar discharge gave rise to a discussion of great interest. We are compelled to hold over our report of this meeting until next week.

There is a general concensus of opinion in the English press that the collapse of the French Copper Syndicate is complete and final. Certain it is that an enormous amount of the "cornered" metal remains on hand far in excess of present requirements; and almost equally certain is it that the Syndicate will have to part with its store at considerable loss. To prevent this loss being too great, or, as the financial newspapers prefer to put it, to prevent the market being utterly demoralised by a glut of copper suddenly thrown upon it, an English Syndicate is said to have come to the rescue, and we are asked to believe that the supply will be doled out at reasonable prices. We are

Digitized by Google

not conversant with the mysteries of the Copper Market, but, speaking as ordinary laymen, we should say that it is just as impossible for an English as for a French ring to maintain, for any length of time, prices at which consumers are not disposed to buy; and with a known supply largely exceeding their demand purchasers are pretty certain to hold off until the commodity is offered, not at its natural value, but at the value to which these recent operations have unnaturally reduced it. In other words, copper ought to be exceedingly cheap, and we fail to see how anybody can prevent its being so in the long run.

We hope and believe that the person who prompted the question put to the Postmaster-General on Monday evening relating to the Submarine Telegraph Company's servants did not represent the whole body of postal telegraph operators at the Central Office. A more ungracious suggestion with regard to an unfortunate body of men of the same profession as themselves could hardly be conceived. The Submarine Company's *employés* are in a far worse plight, through no fault of their own, than were the servants of the old telegraph companies before they were handed over to the Post Office; and to place any sort of hindrance to the Submarine clerks being fairly, and even handsomely, treated by the Government is, to our thinking, inexpressibly mean. We repeat, however, our suspicion that the question was concocted by some self-constituted delegate who knows little of the feelings of his comrades, and still less of the character of the Postmaster-General.

On Wednesday last, at the invitation of the Series Electric Traction Syndicate, a number of representatives of the technical journals proceeded to Northfleet for the purpose of inspecting the working of the electric tramway which has just been completed by the Syndicate in that locality. The line is of no great length (rather under one mile), but it contains a long gradient of about 1 in 32, and several sharp curves, so that it affords every opportunity for testing the capabilities of the system. The running of the two cars left nothing to be desired in point of speed and perfection of control, and, in fact, the whole of the arrangements created a most favourable impression upon the minds of the visitors. Very great skill has been displayed both in the engineering and the purely electrical details, especially in the arrangement of the conduit to form one of the running lines; indeed, we believe that an inspection of the line would go far to dissipate any lingering prejudice which may exist in the minds of our readers against the principle of series working. The fact that by the action of the arrow the "spring-jack" contacts are not only automatically kept bright, but that an incipient fault is at once disclosed and localised by the reading of the ammeter on the car, added to the further fact that the "spring-jacks" can be replaced in five minutes at a trifling cost, seems to us to render it, to say the least, highly improbable that the numerous advantages of the system will be to any sensible degree counterbalanced by the difficulty of maintaining the numerous contacts. We therefore look forward with some degree of confidence to an extensive development of this system.

On Friday last, too late for our current number, we received the following cablegram from our New York correspondent:—

[Cablegram.]

"News received from Canada this morning that Edison lamp patent in the Dominion has been declared void there on account of failure to comply with provisions as to manufacture in the Dominion within a year of issue."

The action in question was brought by the Westinghouse Electric Company and the United States Electric Company. Some further particulars of the case will be found in our issue of Dec. 28th, 1888, page 214.

We print on another page the full text of the report of the Committee on Underground Conduits and Conductors appointed in 1888 by the American National Electric Light Association. The subject is one of the greatest possible interest to English electricians at the present time, and the report merits their most careful consideration. It should, however, be clearly understood, although it is not explicitly stated, that the investigations of the Committee were really confined to the case of high potential circuits. The Edison low potential system of underground mains, with its elaborate devices for securing flexibility as well as insulation, though expensive, has proved a practical success from the first, and the possibility of working circuits of low potential in underground conduits is not called in question. But for currents of high potential the case is different. It will be seen that a circular containing a well-considered series of questions was sent by the Committee to 130 local electric lighting companies in the States. Out of this number no less than 104 replied that in their opinion it is not yet practicable to place wires conveying high-tension arc light currents underground. Of course the value to be attached to this expression of opinion must be suitably discounted by the recollection that all these companies had their capital invested in overhead systems. And it is even possible to suppose that the unanimity of their replies was intended to influence public opinion. On the other hand, the views of seven companies who are actually operating underground conductors of greater or less extent are given in detail in the report. Of these seven the experience of five is strongly adverse to the system, one other had only been in operation a few days, and one solitary individual is able, on the whole, to speak in its favour, though he, too, had had his troubles. A somewhat acrimonious discussion followed the reading of the report, one or two representatives of special conduit devices moving its rejection. It was, however, clear that the general body of members were fully prepared to endorse the action of the Committee.

In this matter, whilst we can only re-echo the advice of Prof. Forbes, that the experience of our American cousins should be duly pondered, yet there are, we think, some considerations of a reassuring character. In the first place, underground mains conveying high tension currents have already been maintained in this country with some degree of success—notably by the Eastbourne Electric Light Company, and, at an earlier date, by the Anglo-American Brush Company in the lighting of the City. It may be relied upon that this experience will not be

Digitized by Google

thrown away. Next, there are some difficulties, such as those occasioned by steam pipes, existing in many American cities, which do not affect us in this country. And lastly, but not least, there is the question of insulation. In America the competition amongst arc-lighting companies is so keen that it would be almost impossible to get a return upon the capital invested if a really high-class insulation were employed. This point was fully admitted in the discussion to which we have alluded. Prof. BARRETT, of Chicago (who had not replied to the circular of the committee) pointed to seven miles of successful underground high potential mains, whilst at the same time he admitted that the extra cost, as compared to an overhead system, amounted to nearly one cent. per lamp per hour. (This calculation is not quite intelligible without further explanation, but we quote it from the report furnished by the American journals.) The system is, however, in the hands of the municipality, and is practically free from commercial competition.

OUR Brussels correspondent informs us that the Municipality of that city have decided to throw open the supply of electric light to public tender. The principal conditions which are imposed will be found in his letter.

WE do not know who is responsible for "the particulars and information furnished" to the Electric Lighting Committee of the Cheltenham Town Council, an abstract of which appeared in our last issue; but we do know that a calculation of revenue based on an estimate of 1,500 hours of burning per annum for every incandescent lamp is in the highest degree fallacious. Experience both in this country and in America has shown that a usage of from 700 to 800 hours per annum is a fair all-round average. But the Cheltenham people would probably do well to be guided by the experience of Leamington—the two towns being very much alike—where it has been found that the private consumers burn their lamps upon the average rather less than 500 hours per annum. We are glad that Cheltenham is alive to the advantages of electric lighting, and we sincerely hope that the Council will see their way to carry out the wishes of the inhabitants; but it is to the interest of all concerned that they should not be misled by financial estimates which will certainly fail to be realised.

THERE is just one remark in the interesting and encouraging speech of the Chairman of the Anglo-American Brush Company to which we venture to demur. Lord THURLOW thinks that "the recent advance of electrical science" is due to the Electric Lighting Act of 1888; but he omitted to explain the exact connection.

London Central Subway Railway Bill.—This Bill was read a second time in the House of Commons on Friday last.

St. Martin-in-the-Fields Vestry.—At a meeting of this Vestry last week it was decided to support the Provisional Order of the Electrical Power Storage Company.

St. John's (Newfoundland).—According to the *Canadian Gazette*, the streets of St. John's are being lighted by the electric light, as well as Government House and the Parliament buildings.

Balloon Signalling.—Further experiments are to be carried out shortly at Chatham by the Balloon Department with the Bruce system of electric balloon signalling. The apparatus used will be that purchased by the Government of the inventor, Mr. Eric Stuart Bruce.

Metropolitan Railway Bill.—This Bill, which empowers the company to use electricity as a motive power and to enable them to run over the Aylesbury and Buckingham Railway, passed the Examiner upon Standing Orders in the House of Commons on Monday last.

The Electric Light at Windsor Castle.—The introduction of the electric light into the corridor at Windsor Castle has been found so great an improvement that it will be extended before long to the White, Crimson and Green Drawing-rooms, the ball-room, and the dining-room.

Society of Arts Motor Trials.—In reference to the recent trials, under the auspices of the Society of Arts, of motors suitable for electric lighting purposes, Professor Kennedy will read a Paper on the subject at the Society of Arts on Wednesday next, when the medals will be presented to the competitors.

Metropolitan Electric Supply Company.—In the House of Commons on Tuesday last, the Committee of Selection decided that the Metropolitan Electric Supply Company's Bill should be taken out of the original group and not go before committee until the London County Council was in operation to give them consideration.

Recent Floods and the Telegraph.—Some damage was done to the telegraph wires and poles by the snowstorms and floods in the Midland and Western counties last week, causing partial interruption and delay to the places north of Birmingham. The injuries were, however, speedily repaired, being very much less serious than they were reported to have been in the newspapers.

The Forth Telegraph Cables.—Telegraphic communication with the North of Scotland has been somewhat interrupted of late by the breakdown of the submarine cable which crosses the Forth between Burntisland and Granton. This has necessitated a visit from the Government cable steamer "Monarch," which is now in the Forth, and is engaged repairing the old and laying a new cable.

St. Saviour's Board of Works.—At a meeting of this Board last week it was decided, on the recommendation of the General Purposes Committee, to consent to the application for Provisional Orders for supplying electricity in the district being made on behalf of the Metropolitan Electric Supply Company and the London Electric Supply Corporation, subject to certain restrictions being allowed.

Lighting of the Hoosac Tunnel.—The leads finally adopted for the electric light installation at the Hoosac Tunnel, Mass., were made by the Standard Underground Cable Company, forty miles of lead-covered cable being laid in wooden conduits in trenches on each side of the tracks. Several kinds of special insulation were tried, but the excessive moisture and sulphurous fumes proved too much for them.

"Electrical World."—During the recent meeting of the National Electric Light Association at Chicago, our contemporary, *The Electrical World*, of New York, issued a "bulletin" twice a day giving a report of the proceedings. These bulletins have been embodied in the current issue of *The Electrical World*, which contains no less than 96 pages. (*The Electrical World* can be obtained at the office of *The Electrician*.)

Dudley.—At the monthly meeting of the Dudley Town Council last week Alderman Bagott, in moving the report of the Streets and Gas Committee, begged the Council to do all in its power to get up a competitive light in the borough. Several members advocated the electric light. After a long discussion on the high price of gas in Dudley, it was unanimously agreed to ask the gas company for a reduction in the prices charged.

Newcastle.—The recommendation of the Town Improvement Committee that the proposed Licences of the Newcastle and District Electric Lighting Company and of the Newcastle Electric Supply Company should be supported, was considered at a meeting of the Newcastle City Council on the 6th instant.

Digitized by Google

After some discussion, the report of the committee was adopted, with the addition of a clause prohibiting a transfer of the Licenses.

Halifax.—The Electric Lighting Committee of the Halifax Town Council met again on Wednesday to consider the various applications for a concession to supply the electric light, but we understand no decision was come to. In the meantime Messrs. Schmidt, Douglas and Co., and Messrs. Blakey, Emmott and Co., are busy canvassing, and the latter firm have already got to work by supplying lights in Corn market, Market-street, and Northgate.

A New Alloy.—A new alloy has been made by Herr Reith, of Bockenheim, Germany, which is said to practically resist the attack of most acid and alkaline solutions. Its composition is as follows:—Copper, 15 parts; tin, 2·34 parts; lead, 1·82 parts; antimony, 1 part. This alloy is, therefore, a bronze with the addition of lead and antimony. The inventor claims that it can be very advantageously used in the laboratory to replace vessels or fittings of ebonite, vulcanite, or porcelain.

Institution of Electrical Engineers—Students' Meeting.—A meeting was held on Friday, March 8th, at 8 p.m., Mr. Guy C. Fricker, A.I.E.E., in the chair. The discussion on Mr. H. W. Handcock's Paper on "Ship Lighting and the Aspects of Electrical Industries in the Colonies" was opened by Mr. J. Rance, Jun., and continued by the Chairman and Messrs. Müller and Childs. Mr. Handcock replied, and a vote of thanks to Mr. Fricker for presiding terminated the proceedings.

Obituary.—We regret to learn that Mr. Joaquin de Mancha, Chairman of the Cuba Submarine Telegraph Company, died suddenly on Sunday morning, the 10th inst., at his residence, Springfield, Clapham Park. Mr. de Mancha, who was head of the firm of Messrs. Mancha and Co., Spanish merchants, joined, by invitation, the Board of the Cuba Submarine Telegraph Company in 1874, and was elected to the chairmanship on the retirement of Mr. Hughes, Q.C., in 1882. He was in his 71st year.

Clerkenwell Vestry.—At a meeting of this Vestry last week the Works Committee reported upon the applications from the London Electric Supply Corporation and the Metropolitan Electric Supply Corporation for the consent of the Vestry to their Provisional Orders. The committee recommended "That the terms and conditions be approved, and that no opposition be offered to the application for Provisional Orders, and that the companies be informed that the Vestry deem it desirable that a station for generating electricity should be in this parish." The motion was adopted.

"Work."—The first number of a new weekly journal, entitled "Work: an Illustrated Magazine of Practice and Theory for all Workmen, Professional and Amateur," will make its appearance on the 20th of March. We are led to expect that in the pages of "Work" will be found a clear and practical exposition of methods to be followed in every art, craft, and science that bears directly or indirectly on handiwork of a constructive or decorative character, freely illustrated with sketches, diagrams, or working drawings to scale. Messrs. Cassell and Company are the publishers.

Sheffield.—The Sheffield Telephone Exchange and Electric Light Company have recently completed some extensive structural alterations at their works in Station-road, by which the size of the engine and machine rooms and the capacity for output have been more than doubled. Additional plant has also been laid down, comprising a 100lbs. pressure steel boiler and a horizontal condensing engine, which drives a 35,000 Watt-Mordey alternator. The demand for light is growing very rapidly, and, amongst other places, the hotel which the Café Company will open shortly in Fargate is to be lighted throughout by electricity.

Prof. Forbes' Paper on "Central Station Lighting"—Some Corrections.—Prof. G. Forbes requests us to make the following corrections to Part II. of his Paper on "Central Station Lighting," as issued by the Institution of Electrical Engineers:—P. 507, column 1, line 9, for "57 yards," read "40 or 50 yards"; p. 508, column 1, line 15, for "the waste due to magnetic friction . . . . . induction in the iron is the same," read "the waste due to magnetic friction varies as the length of the magnetic circuit, if the induction in the iron is the same"; p. 508, column 2, line 33 from end of article, for "great," read "frequent."

Indian Telegraph Department.—The annual Administration Report of the Indian Telegraph Department shows that 5,014 miles of new wires and cables were laid during the past year, making a total of nearly 94,000 miles. The net revenue from the telegraphs was over 23 lacs, being the largest ever recorded, and more than 50 per cent. over the average of the three previous years. Over 2,800,000 messages were sent, an increase of nearly 12 per cent. on the year 1886. The reduction in charges for telegraphic money orders has resulted in a great development of this traffic. The excellent services rendered by Sir A. Leppoc Cappel, the retired Director-General, are acknowledged by Government.

The Royal Meteorological Society's Exhibition.—The Royal Meteorological Society's tenth annual exhibition of instruments will be held at the Institution of Civil Engineers, 25, Great George-street, Westminster, in conjunction with the society's meeting on Wednesday, the 20th inst., and will be very interesting and instructive. The exhibition is specially devoted to actinometers and solar radiation apparatus. It will also include several new instruments, and a number of photographs of flashes of lightning, clouds, &c. The exhibition will remain open till Friday, the 22nd inst. Persons, not Fellows, wishing to visit the exhibition can obtain tickets on application to Mr. W. Marriott, Royal Meteorological Society, 30, Great George-street, S.W.

Exports of Telegraphic Wire and Apparatus connected therewith.—The figures shown by the last Board of Trade returns are not altogether unsatisfactory, though they do not amount to one-third of the value of the exports for January, which, it will be remembered, were quite exceptional. The following is a comparative statement:—

	1886.	1887.	1888.
Year	£992,667	£817,385	£521,174
	1887.	1888.	1889.
January.....	£14,442	£41,231	£113,230
February	44,137	14,051	32,086
Two months.....	£58,579	£55,282	£145,316

St. Margaret's and St. John's (Westminster).—At a meeting of this Vestry last week the Parliamentary Committee reported that they had had the following electric lighting schemes before them: Kensington and Knightsbridge Electric Lighting Company, Metropolitan Electric Supply Company, London Electric Supply Corporation, Westminster Electric Lighting Company, St. George's (Hanover Square) Electric Lighting Company, and the House-to-House Electric Light Supply Company. They recommended that objections should be lodged against the whole of them. The committee was still proceeding upon the reference by the Vestry, empowering them to fully inquire into the whole question of electric lighting, with a view to the Vestry undertaking the supply of the light in that district themselves. The report and recommendations were unanimously adopted.

The Liquefaction of Gases by Electricity.—An electrolytic method of liquefying gases has been described by H. N. Warren in the *Chemical News*. Strong hydrochloric acid is introduced into a combustion tube, bent at right angles, so as to cover two small platinum plates fused into the closed end of the tube; a plug of asbestos, saturated with concentrated sulphuric acid, is placed at the bend; the open and shorter arm is then fused up and immersed in a freezing mixture. On the passage of a current through the plates gas is evolved and liquefies at the other end; but on removing the tube from the freezing mixture and discontinuing the current the liquefied hydrogen chloride is reabsorbed by the water. The experiment may then be repeated. Other compound gases behave in a similar manner. When acidified water is decomposed in this apparatus, and a platinum plate covered with platinum-black has been fused in the short end, explosions occur there at intervals, and small quantities of water form, containing hydrogen peroxide, and having an

Digitized by Google

ozonised odour. With chromic acid and water the blue oxide of chromium is obtained. The method has also been applied to the liquefaction of oxygen and hydrogen, and the latter is said to have been "decidedly liquefied."

Continuous-Current Machines by Ganz and Co.—For the last two years the firm of Ganz and Co., of Buda Pesth, have been building continuous-current machines with drum armatures. The following table gives some data with regard to these machines:—

Data.	No. 0.	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.
Maximum power in watts	1,650	3,000	7,200	10,800	22,000	44,000
Maximum current in amperes ..	15	60	120	180	200	400
Difference of potential in volts..	100–110	100–110	100–110	100–110	100–110	100–110
Revolutions per minute	1,400	900	700	600	500	375
Diameter of commutator in mm.	110	130	156	170	170	26
Length of commutator in mm. ..	80	90	130	126	134	178

Meeting of the Electric Light Association at Chicago.—Up to the time of going to press the letter from our New York correspondent has not reached us. It would probably have contained an account of the proceedings of the ninth meeting of the National Electric Light Association at Chicago. With the exception of the report of the committee on underground mains, which we print elsewhere, the Papers read at this meeting are of less interest than usual to English readers. The following is a summary of the proceedings:—

President's Address. By S. A. Duncan.
Report of Committee on Patent Legislation. By A. Steuart.
Report of the Committee on Underground Conduits and Conductors. By E. T. Lynch, jun.
Report of the Executive Committee. By B. E. Sunny.
Electric Light Stations as Fire Risks. By S. E. Barton.
Report on the New England Electric Exchange. By P. H. Alexander.
Disruptive Discharges in Lead Cables. By C. H. Rudd.
Fuel Oil. By S. S. Leonard.
Oil as Fuel. By M. J. Francisco.
The Advantages of Oil as a Fuel. By C. M. Ransom.
Municipal Lighting. By F. H. Whipple.
Municipal Ownership of Natural Monopolies. By A. R. Foote.
Conduits: Their Material in Relation to Insulated Conductors. By A. C. Chenoweth.

Popular Lectures.—A series of three lectures on "Electricity in the Service of Man" is now being given by Mr. Lant Carpenter, at the Polytechnic in Regent-street. These lectures, which are delivered under the auspices of the London Society for the Extension of University Teaching, have so far proved a great success, as many as 1,250 persons being present. The audiences, moreover, have been largely composed of artizans. Last Friday Mr. William M'Whirter also delivered a lecture upon the same subject at Aberdeen. In the course of his remarks, Mr. M'Whirter referred to the wonderful progress of telegraphy. Great reductions, he said, had been made in the cost of telegrams. In 1840 the charge from London to Stafford or Birmingham was just under 4d. per word; to Liverpool, Leeds, or Manchester it was over 5d.; to York it was nearly 6d.; to Edinburgh it was just under 8d.; to Glasgow it was 8¾d.; and to Derby 4½d. In 1855 the number of telegrams sent was 882,360; in 1865 the number rose to 4,650,231; in 1875 the number of messages went up to 19¼ millions; and in the year 1885-86, when the sixpenny telegrams had been in force, the increase amounted to 47½ millions. The lecture was illustrated throughout by interesting experiments.

A Central Station at Strathearn.—The Strathearn Hydropathic Company are engaged in laying down what is practically a small central station in the Hydropathic Crieff. It is intended not only to light the Institution itself, but to extend the field of operations to several villas in the town, and to light the outhouses, and to supply power all over the building, and to a threshing machine in the stables. There is a great deal of water-power going to waste round the town, but the fashionable character of the locality decided the use of other motive power. The matter was placed in the hands of Mr. C. H. Yeaman, of London, and, after some careful tests at the manufacturer's works, the Griffin gas-engine of the double-acting type was decided on, and a 24 B.H.P. engine, running at 200 revolutions, is being laid down. The engine and accumulator rooms are directly under the main public rooms, but sunk several feet below any other part of the building. The dynamo employed is one of Messrs. Laurence, Paris and Scott's, of Norwich, giving 100 volts and 120 amperes at 850 revolutions. To start with, a little over 150 lights are being fitted, and the engine plant alone will be used. Messrs. Anderson and Munro, of Glasgow, are wiring the house, and are introducing their quick break switches and Trotter's dioptric globes.

The Overhead Wire Question in Brooklyn.—The Board of Commissioners of Electrical Subways has recently published its report for 1888. The aggregate length of conductors underground has been increased from 1,433 to 2,928 miles. There are now 2,978 miles of wire underground, with 5,117 miles of aerial conductors, against 4,659·2 miles, all aerial, in 1886. Of the aggregate 5,117 miles of aerial conductors, those of the various district telegraph companies and of the Gold and Stock Telegraph Company occupy house-tops and not poles, and the Board has permitted their operation because of the difficulty of concentrating this small but scattered mileage in conduits. There are 4,402 miles of telegraph and telephone wires more immediately the subject of the operations of the Board. "Of this amount it is reasonable," says the report, "to expect that nearly all of the 236 miles of the telegraph wires now carried on poles will be removed. Of the remaining 4,176 miles of telephone wires a considerable proportion is required for terminal distribution in connection with the subway system. The removals of wires in 1888 included 714 miles removed by the New York and New Jersey Telephone Company, 20 miles by the Western Union Telegraph Company, and 50 miles by the electric light companies, a total of 784 miles. The telephone companies removed 72 and the other companies 245 poles, a total of 317 poles removed in 1888. Since the Board was organised 335 poles and 1,400 miles of aerial wires have been removed. The actual extension of the system by construction of additional conduits has been 1·58 miles, giving a present aggregate length of conduit of 15·78 miles. The aggregate length of ducts is now 109·78 miles.

Cheltenham.—The adjourned meeting of the Town Council was held on Monday last to take into consideration the report of the Electric Lighting Committee, which gave an approximate estimate of the cost of laying down plant, &c., sufficient for 60 arc lamps of 1,200 candle-power each, and 2,300 incandescent lamps of 16 candle-power each, site and buildings at £11,900, the annual cost of production of which would be £3,300 to £3,700. Mr. Norman, in opening the discussion, pointed out that the Corporation had already affirmed the desirability of the introduction of the light, and that it should be undertaken by the Corporation. Having commented on the advance that had been made in the electric lighting of towns and trade premises, he proceeded to give statistics as to the use of the light in London, Taunton, Bradford, Leamington, and Bath. Bath—once regarded as a sleepy place—was going a-head in the matter, as they were going to have 86 lamps at a cost of £2,000 a year; therefore it must be worth the while of Cheltenham to incur the very small expenditure which the Committee estimated would be necessary if the project were carried out. Mr. Norman said the Committee proposed that tenders should be invited for lighting with arc and incandescent lamps, either or both of which the Council might adopt. The adoption of both systems would yield a profit, the Committee believed, that would largely pay for the lighting of their streets, an income being derivable from the use of the incandescent lamp which would not be obtainable from the arc light alone. After some further observations he moved the adoption of the report. A lengthy discussion followed. The Committee's report was finally adopted by 11 to 4. It empowers the Committee to proceed with the matter, and procure tenders to be submitted to the Council.

ON THE LOCALISATION OF A PARTIAL-EARTH FAULT IN A SUBMARINE CABLE BY FALL OF THE FAULT'S NATURAL POTENTIAL.

BY HAROLD W. ANSELL AND JULIAN E. YOUNG.

The following modification of the "fall of potential" test for partial-earth faults in submarine cables has been found not only to admit of successful application to practical localisation work, but to possess in certain cases distinct advantages over the ordinary method. A brief account of it may therefore present an interest more than exclusively theoretical to those engaged in such work.

The principle on which it is based consists in the employment of the electromotive force, whether natural or secondary, existing at a partial-earth fault, in place of that of a testing battery. This electromotive force, as is well known, may arise from the simple exposure of the conductor of the cable in sea-water; or, as a secondary effect, from its polarisation by the passage of currents through the fault, as well as from the presence of earth-currents. In general it is due to a combination of the three.

Suggestions have already been made that the natural currents entering a cable at an earth-fault might be utilised for purposes of localisation; but it seems to have been found that they are in general neither of sufficient strength nor constancy for resistance measurements by the bridge methods. Up to the present the general tendency of investigation has been to endeavour to eliminate rather than to utilise such currents, as well as the secondary electromotive force generated by the application of a battery. The potential of these extraneous

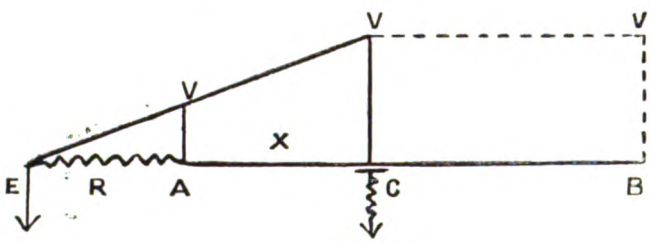

FIG. 1.

currents is, however, in most cases sufficiently high for accurate measurement by means of an electrometer or by condenser discharge through a sensitive galvanometer.

In the following test this potential is applied by means of a method analogous to that described in Kempe's Handbook (4th edition, page 386) to localisation of faults.

The theory of the method is illustrated by Fig. 1, in which A B represents a submarine cable, having a partial-earth fault at C, at a distance x from the end A. R is a resistance inserted between A and earth. The potential of the natural currents entering the cable at C is represented by the vertical V at that point, falling to v at A and to zero at E. Then, by similar triangles, we have

$$x = R\frac{V - v}{v}.$$

The potential V is measured at B, whilst v is observed at A.

When the potentials are sufficiently large the mode of observing them by their permanent deflections through a high resistance is preferable for simplicity of manipulation; but the electrometer or condenser method of measurement may be used should it be required to increase the size of the readings. Simultaneous series of values of V and v must of course be obtained, and the readings at each end taken as rapidly as possible, each station converting the observed potential into terms of some standard of E.M.F., such as Clark's cell.

In practice it will be found that the potentials usually present at exposures give values of V and v sufficiently high for accurate comparison by means of one or other of the foregoing methods. In the case of long cables the earth-currents entering at the exposure would generally furnish the greater part of the potential and determine its sign. The effect of the variations in the earth-current may be minimised by taking the mean of a series of readings of V and v, the absolute values it which do not affect the result. Under certain conditions of might happen that the potentials of the earth and fault currents were equal and opposite, but this seldom lasts for any great length of time. When, however, the natural electromotive force at the fault is found too feeble, the application of a positive current from a battery for a few minutes will generate a secondary electromotive force, which, after removing the battery, furnishes the necessary potential for making the test.

The value of x thus arrived at is evidently independent of the resistance of the exposure, as in the usual "fall of potential" test.

Such a system of measurement may be found in some cases more advantageous than that usually employed from the fact that only two potentials require to be observed, instead of three, that no corrections for earth-currents are necessary, and that the fault is undisturbed by the influence of testing currents during the period of observation. Again, in the case of a cable having an exposure of low resistance, the potential of a battery current falls at the fault to a very low value, in measuring which at the other end of the cable a very small reading will generally be obtained. It is obvious that a small error made in observing this will produce a considerable error in the resulting value of x. When, however, such a fault is itself made to constitute the testing battery, although the

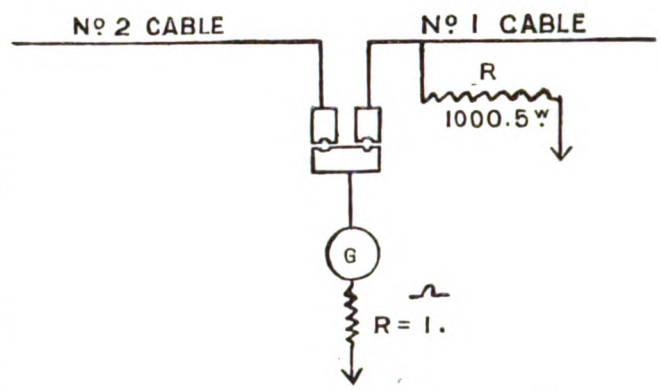

FIG. 2.

resistance of the exposure may be very low, yet the potential at that point is still, within the limits before alluded to, high enough to give a moderately large reading at the end of the cable, in which case a slight error of observation has little influence on the result.

In the following example the foregoing test was applied to the localisation of a fault in one of the cables of the Eastern Telegraph Company, by whose permission it is appended:—

In this case a second cable was looped with that containing the fault, and the two potentials were thus both observed on the same galvanometer, the readings being taken through a resistance of a megohm. A resistance of 1,000·5 ohms was inserted between the end of the faulty cable and earth, and the potential v measured at the junction of the cable with the resistance; whilst the potential V was observed at the end of No. 2 cable. The fault was polarised with a positive current from 20 Leclanchés for three minutes, in order to raise the potentials to a convenient degree; and it was found unnecessary to further increase the deflections by the use of a condenser. After removing the battery, the potentials were found to rise steadily for about five minutes, when they attained a maximum; after which they decreased with unsteadiness. The polarising current was then again applied, and another series taken, the readings being always observed alternately, and as rapidly as possible.

Table A on next page shows one of the series so obtained, from which

$$x = \frac{95 - 33{\cdot}6}{33{\cdot}6} \times 1{,}000{\cdot}5 \text{ ohms.}$$

$$= 1{,}828{\cdot}3 \text{ ohms.}$$

This, in conjunction with a few other readings similarly obtained, gave a mean value of $x = 1{,}820$ ohms. The actual distance of

Digitized by Google

the fault, as subsequently ascertained by the repairing steamer, was 1,846 ohms, its minimum resistance being about 100 ohms. The total length of the looped cables was 720 knots, having a resistance of 5,960 ohms.

It may be mentioned that in the ordinary "loop-potential" test, applied to the same fault, the potential at the exposure fell to a value of 0·085 of that of the battery, an inconveniently small proportion.

THE DISCHARGE OF A LEYDEN JAR.*

It is one of the great generalisations established by Faraday, that all electrical charge and discharge is essentially the charge and discharge of a Leyden jar. It is impossible to charge one body alone. Whenever a body is charged positively, some other body is *ipso facto* charged negatively, and the two equal opposite charges are connected by lines of induction. The charges are, in fact, simply the ends of these lines, and it is as impossible to have one charge without its correlative as it is to have one end of a piece of string without there being somewhere, hidden it may be, split up into strands it may be, but somewhere existent, the other end of that string.

This I suppose familiar fact that all charge is virtually that of a Leyden jar being premised, our subject for this evening is at once seen to be a very wide one, ranging, in fact, over the whole domain of electricity. For the charge of a Leyden jar includes virtually the domain of electrostatics; while the discharge of a jar, since it constitutes a current, covers the ground of current electricity all except that portion which deals with phenomena peculiar to steady currents. And since a current of electricity necessarily magnetises the space around it, whether it flows in a straight or in a curved path, whether it flow through wire or burst through air, the territory of magnetism is likewise invaded; and inasmuch as a Leyden jar discharge is oscillatory, and we now know the vibratory motion called light to be really an oscillating electric current, the domain of optics is seriously encroached upon.

But though the subject I have chosen would permit this wide range, and though it is highly desirable to keep before our minds the wide-reaching import of the most simple-seeming fact in connection with such a subject, yet to-night I do not intend to avail myself of any such latitude, but to keep as closely and distinctly as possible to the Leyden jar in its homely and well-known form, as constructed out of a glass bottle, two sheets of tinfoil and some stickphast.

The act of charging such a jar I have permitted myself now for some time to illustrate by the mechanical analogy of an inextensible endless cord able to circulate over pulleys, and threading in some portion of its length a row of tightly-gripping beads which are connected to fixed beams by elastic threads.

The cord is to represent electricity; the beads represent successive strata in the thickness of the glass of the jar, or, if you like, atoms of dielectric or insulating matter. Extra tension in the cord represents negative potential, while a less tension (the nearest analogue to pressure adapted to the circumstances) represents positive potential. Forces applied to move the cord, such as winches or weights, are electromotive forces; a clamp or fixed obstruction represents a rheostat or contact-breaker; and an excess or defect of cord between two strata of matter represents a positive or a negative charge.

The act of charging a jar is now quite easily depicted, as shown in the diagram on next column.

To discharge the jar one must remove the charging E.M.F. and unclamp the screw, *i.e.*, close the circuit. The stress in the elastic threads will then rapidly drive the cord back, the inertia of the beads will cause it to overshoot the mark, and for an instant the jar will possess an inverse charge. Back again the cord swings, however, and a charge of same sign as at first, but of rather less magnitude, would be found in the jar if the operation were now suspended. If it be allowed to go on, the oscillations gradually subside, and in a short time everything is quiescent, and the jar is completely discharged.

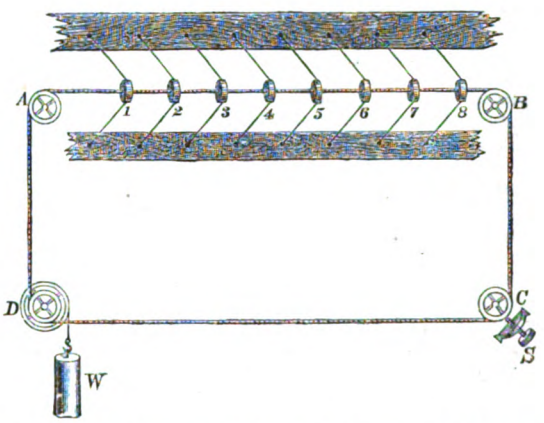
All this occurs in the Leyden jar, and the whole series of oscillations, accompanied by periodic reversal and re-reversal of the charges of the jar, is all accomplished in the incredibly short space of time occupied by a spark.

Consider now what the rate of oscillation depends on. Manifestly on the elasticity of the threads and on the inertia of the matter which is moved. Take the simplest mechanical analogy, that of the vibration of a loaded spring, like the reeds in a musical box. The stiffer the spring, and the less the load, the faster it vibrates. Give a mathematician these data, and he will calculate for you the time the spring takes to execute one complete vibration, the "period" of its swing. [Loaded lath in vice.]

The electrical problem and the electrical solution are precisely the same. That which corresponds to the flexibility of the spring is in electrical language called static capacity, or, by Mr. Heaviside, permittance. That which corresponds to the inertia of ordinary matter is called electro-magnetic inertia, or self-induction, or, by Mr. Heaviside, inductance.

Increase either of these, and the rate of oscillation is diminished. Increasing the static capacity corresponds to lengthening the spring; increasing the self-induction corresponds to loading it.

Now the static capacity is increased simply by using a larger jar, or by combining a number of jars into a battery in the very old-established way. Increase in the self-induction is attained by giving the discharge more space to magnetise, or by making it magnetise a given space more strongly. For electro-magnetic



Mechanical analogy of a circuit partly *dielectric*: for instance, of a charged condenser. A is its positive coat, B its negative, C D pull ys, W weight, S set screw.

inertia is wholly due to the magnetisation of the space surrounding a current, and this space may be increased or its magnetisation intensified as much as we please.

To increase the space we have only to make the discharge take a long circuit instead of a short one. Thus, we may send it by a wire all round the room, or by a telegraph wire all round a town, and all the space inside it and some of that outside will be more or less magnetised. More or less, I say; and it is a case of less rather than more. Practically very little effect is felt except close to the conductor, and accordingly the self-induction increases very nearly proportionally to the length of the wire, and not in proportion to the area enclosed, provided the going and return wires are kept a reasonable distance apart, so as not to encroach upon each other's appreciably magnetised regions.

But it is just as effective, and more compact, to intensify the magnetisation of a given space by sending the current hundreds of times round it instead of only once; and this is done by inserting a coil of wire into the discharge circuit.

Yet a third way there is of increasing the magnetisation of a given space, and that is to fill it with some very magnetisable substance, such as iron. This, indeed, is a most powerful method under many circumstances, it being possible to increase the magnetisation, and therefore the self-induction or inertia of the current, some 5,000 times by the use of iron.

But in the case of the discharge of a Leyden jar iron is of no advantage. The current oscillates so quickly that any iron introduced into its circuit, however subdivided into thin wires it may be, is protected from magnetism by inverse currents induced in its outer skin, as your Professor of Natural Philosophy* has shown, and

* Friday evening discourse at the Royal Institution of Great Britain, on March 8, by Prof. Oliver Lodge, F.R.S. We are indebted to the Editor of *Nature* for advanced proofs of this Lecture.

* Lord Rayleigh

Digitized by Google

accordingly it does not get magnetised ; and so far from increasing the inductance of the discharge circuit it positively diminishes it by the reaction effect of these induced currents ; it acts, in fact, much as a similar mass of tin might be expected to do.

The conditions determining rate of oscillation being understood we have next to consider what regulates the damping out of the vibrations, *i.e.*, the total duration of the discharge.

Resistance is one thing. To check the oscillations of a vibrating spring you apply to it friction, or make it move in a viscous medium, and its vibrations are speedily damped out. The friction may be made so great that oscillations are entirely prevented, the motion being a mere dead-beat return to the position of equilibrium ; or, again, it may be greater still, and the motion may correspond to a mere leak or slow sliding back, taking hours or days for its accomplishment. With very large condensers, such as are used in telegraphy, this kind of discharge is frequent, but in the case of a Leyden jar discharge it is entirely exceptional. It can be caused by including in the circuit a wet string, or a capillary tube full of distilled water, or a slab of wood, or other atrociously bad conductor of that sort ; but the conditions ordinarily associated with the discharge of a Leyden jar, whether it discharge through a long or a short wire, or simply through its tongs, or whether it overflow its edge or puncture its glass, are such as correspond to oscillations, and not to leak. [Discharge jar through capillary water tube.]

When the jar is made to leak through wood or water the discharge is found to be still not steady : it is not oscillatory, indeed, but it is intermittent. It occurs in a series of little jerks, as when a thing is made to slide over a resined surface. The reason of this is that the terminals discharge faster than the circuit can supply the electricity, and so the flow is continually stopped and begun again.

Such a discharge as this, consisting really of a succession of small sparks, may readily appeal to the eye as a single flash, but it lacks the noise and violence of the ordinary discharge ; and any kind of moving mirror will easily analyse it into its constituents and show it to be intermittent. [Look at sparks waggling head or opera-glass.]

It is pretty safe to say, then, that whenever a jar discharge is not oscillatory it is intermittent, and when not intermittent is oscillatory. There is an intermediate case when it is really dead beat, but it could only be hit upon with special care, while its occurrence by accident must be rare.

So far I have only mentioned resistance or friction as the cause of the dying out of the vibrations ; but there is another cause, and that a most exciting one.

The vibrations of a reed are damped partly indeed by friction and imperfect elasticity, but partly also by the energy transferred to the surrounding medium and consumed in the production of sound. It is the formation and propagation of sound-waves which largely damp out the vibrations of any musical instrument. So it is also in electricity. The oscillatory discharge of a Leyden jar disturbs the medium surrounding it, carves it into waves which travel away from it into space : travel with a velocity of 185,000 miles a second : travel precisely with the velocity of light. [Tuning fork.]

The second cause, then, which damps out the oscillations in a discharge circuit is *radiation—electrical* radiation, if you like so to distinguish it, but it differs in no respect from ordinary radiation (or "radiant heat," as it has so often been called in this place), it differs in no respect from Light except in the physiological fact that the retinal mechanism, whatever it may be, responds only to waves of a particular, and that a very small, size, while radiation in general may have waves which range from 10,000 miles to a millionth of an inch in length.

The seeds of this great discovery of the nature of light were sown in this place ; it is all the outcome of Faraday's magneto-electric and electrostatic induction ; the development of them into a rich and full-blown theory was the greatest part of the life-work of Clerk-Maxwell ; the harvest of experimental verification is now being reaped by a German ; but by no ordinary German. Dr. Hertz, now Professor in the Polytechnicum of Karlsruhe, is a young investigator of the highest type. Trained in the school of Helmholtz, and endowed with both mathematical knowledge and great experimental skill, he has immortalised himself by a brilliant series of investigations which have cut right into the ripe corn of scientific opinion in these islands, and by the same strokes as have harvested the grain have opened up wide and many branching avenues to other investigators.

At one time I had thought of addressing you this evening on the subject of these researches of Hertz, but the experiments are not yet reproducible on a scale suited to a large audience, and I have been so closely occupied with some not wholly dissimilar, but independently-conducted, researches of my own—researches led up to through the unlikely avenue of lightning conductors—that I have had as yet no time to do more than verify some of them for my own edification.

In this work of repetition and verification Prof. Fitzgerald has, as related in a recent number of *Nature*, probably gone further ; and if I may venture a suggestion to your hon. secretary, I feel sure that a discourse on Hertz's researches from Prof. Fitzgerald next year would be not only acceptable to you, but would be highly conducive to the progress of science.

I have wandered a little from my Leyden jar, and I must return to it and its oscillations. Let me very briefly run over the history of our knowledge of the oscillatory character of a Leyden jar discharge. It was first clearly realised and distinctly stated by that excellent experimentalist, Joseph Henry, of Washington, a man not wholly unlike Faraday in his mode of work though doubtless possessing to a less degree that astonishing insight into intricate and obscure phenomena ; wanting also in Faraday's circumstantial advantages.

This great man arrived at a conviction that the Leyden jar discharge was oscillatory by studying the singular phenomena attending the magnetisation of steel needles by a Leyden jar discharge, first observed in 1824 by Savary. Fine needles, when taken out of the magnetising helices, were found to be not always magnetised in the right direction, and the subject is referred to in German books as anomalous magnetisation. It is not the magnetisation which is anomalous, but the currents which have no simple direction ; and we find in a memoir published by Henry, in 1842, the following words :—

"This anomaly, which has remained so long unexplained, and which, at first sight, appears at variance with all our theoretical ideas of the connection of electricity and magnetism, was, after considerable study, satisfactorily referred by the author to an action of the discharge of the Leyden jar which had never before been recognised. The discharge, whatever may be its nature, is not correctly represented (employing for simplicity the theory of Franklin) by the single transfer of an imponderable fluid from one side of the jar to the other ; the phenomenon requires us to admit *the existence of a principal discharge in one direction and then several reflex actions backward and forward, each more feeble than the preceding, until the equilibrium is obtained.* All the facts are shown to be in accordance with this hypothesis, and a ready explanation is afforded by it of a number of phenomena, which are to be found in the older works on electricity, but which have until this time remained unexplained."*

The italics are Henry's. Now if this were an isolated passage it might be nothing more than a lucky guess. But it is not. The conclusion is one at which he arrives after a laborious repetition and serious study of the facts, and he keeps the idea constantly before him when once grasped, and uses it in all the rest of his researches on the subject. The facts studied by Henry do, in my opinion, support his conclusion, and if I am right in this it follows that he is the original discoverer of the oscillatory character of a spark, although he does not attempt to state its theory. That was first done, and completely done, except as regards radiation loss of energy, in 1853, by Sir William Thomson ; and the progress of experiment by Feddersen, Helmholtz, Schiller and others, has done nothing but substantiate it.

The writings of Henry have been only quite recently collected and published by the Smithsonian Institution of Washington in accessible form, and accordingly they have been far too much ignored. The two volumes contain a wealth of beautiful experiments clearly recorded, and well repay perusal.

The discovery of the oscillatory character of a Leyden jar discharge may seem a small matter, but it is not. One has only to recall the fact that the oscillators of Hertz are essentially Leyden jars—one has only to use the phrase "electro-magnetic theory of light" to have some of the momentous issues of this discovery flash before one.

One more extract I must make from that same memoir by Henry,† and it is a most interesting one ; it shows how near he was, or might have been, to obtaining some of the results of Hertz, though, if he had obtained them, neither he nor any other experimentalist could possibly have divined their real significance.

It is, after all, the genius of Maxwell and of a few other great theoretical physicists whose names are on everyone's lips‡ which endows the simple induction experiments of Hertz and others with such stupendous importance.

Here is the quotation :—

"In extending the researches relative to this part of the investigations, a remarkable result was obtained in regard to the distance at which induction effects are produced by a very small quantity of electricity ; a single spark from the prime conductor of a

* "Scientific Writings of Joseph Henry," Vol. I., p. 201. Published by the Smithsonian Institution, Washington, 1886.

† *Loc. cit.*, p. 204.

‡ And of one whose name is not yet on everybody's lips, but whose profound researches into electro-magnetic waves have penetrated further than anybody yet understands into the depths of the subject, and whose Papers have very likely contributed largely to the theoretical inspiration of Hertz, I mean that powerful mathematical physicist, Mr. Oliver Heaviside.

Digitized by Google

machine, of about an inch long, thrown on to the end of a circuit of wire in an upper room, produced an induction sufficiently powerful to magnetise needles in a parallel circuit of wire placed in the cellar beneath, at a perpendicular distance 30 feet, with two floors and ceilings, each 14 inches thick, intervening. The author is disposed to adopt the hypothesis of an electrical *plenum* [in other words, of an ether], and from the foregoing experiment it would appear that a single spark is sufficient to disturb perceptibly the electricity of space throughout at least a cube of 400,000 feet of capacity; and when it is considered that the magnetism of the needle is the result of the difference of two actions, it may be further inferred that the diffusion of motion in this case is almost comparable with that of a spark from a flint and steel in the case of light."

Comparable it is, indeed, for we now know it to be the self-same process.

One immediate consequence and easy proof of the oscillatory character of a Leyden jar discharge is the occurrence of phenomena of sympathetic resonance.

Everyone knows that one tuning fork can excite another at a reasonable distance if both are tuned to the same note. Everyone knows, also, that a fork can throw a stretched string attached to it into sympathetic vibration if the two are tuned to unison or to some simple harmonic. Both these facts have their electrical analogue. I have not time to go fully into the matter to-night, but I may just mention the two cases which I have myself specially noticed.

A Leyden jar discharge can so excite a similarly-timed neighbouring Leyden jar circuit as to cause the latter to burst its dielectric if thin and weak enough. The well-timed impulses accumulate in the neighbouring circuit till they break through a quite perceptible thickness of air. Put the circuits out of unison by varying the capacity or by including a longer wire in one of them; then, although the added wire be a coil of several turns, well adapted to assist mutual induction as ordinarily understood, the effect will no longer occur.

That is one case, and it is the electrical analogue of one tuning-fork exciting another. It is too small at present to show here satisfactorily, for I only recently observed it, but it is exhibited in the library at the back.

The other case, analogous to the excitation of a stretched string of proper length by a tuning fork, I published last year under the name of the experiment of the recoil kick, where a Leyden jar circuit sends waves along a wire connected by one end with it, which waves splash off at the far end with an electric brush or long spark.

I will show merely one phase of it to-night, and that is the reaction of the impulse accumulated in the wire upon the jar itself, causing it to either overflow or burst. [Sparks of gallon or pint jar made to overflow by wire round room.]*

The early observations by Franklin on the bursting of Leyden jars, and the extraordinary complexity or multiplicity of the fracture that often results, are most interesting.

His electric experiments, as well as Henry's, well repay perusal, though of course they belong to the infancy of the subject.

He notes the striking fact that the bursting of a jar is an extra occurrence; it does not replace the ordinary discharge in the proper place, it accompanies it; and we now know that it is precipitated by it, that the spark occurring properly between the knobs sets up such violent surgings that the jar is far more violently strained than by the static charge or mere difference of potentials between its coatings; and if the surgings are at all even roughly properly timed, the jar is bound to either overflow or burst.

Hence a jar should always be made without a lid, and with a lip protruding a carefully considered distance above its coatings; not so far as to fail to act as a safety valve, but far enough to prevent overflow under ordinary and easy circumstances.

And now we come to what is after all the main subject of my discourse this evening, viz., the optical and audible demonstration of the oscillations occurring in the Leyden jar spark. Such a demonstration has, so far as I know, never before been attempted, but if nothing goes wrong we shall easily accomplish it.

And first I will do it audibly. To this end the oscillations must be brought down from their extraordinary frequency of a million or hundred thousand a second to a rate within the limits of human audition. One does it exactly as in the case of the spring—one first increases the flexibility and then one loads it. [Spark from battery of jars and varying sound of same.]

Using the largest battery of jars at our disposal, I take the spark between these two knobs—not a long spark, ¼in. will be quite sufficient. Notwithstanding the great capacity, the rate of vibration is still far above the limit of audibility, and nothing but the customary crack is heard. I next add inertia to the circuit by including a great coil of wire, and at once the spark changes character, becoming a very shrill but an unmistakable whistle, of a quality approximating to the cry of a bat. Add another coil, and down comes the pace once more, to something like 5,000 per second, or about the highest note of a piano. Again and again I load the circuit with magnetisability, and at last the spark has only 500 vibrations a second, giving the octave above the middle C.

One sees clearly why one gets a musical note: the noise of the spark is due to a sudden heating of the air; now if the heat is oscillatory, the sound will be oscillatory too, but both will be an octave above the electric oscillation, if I may so express it, because two heat-pulses will accompany every complete electric vibration, the heat production being independent of direction of current.

Having thus got the frequency of oscillation down to so manageable a value, the optical analysis of it presents no difficulty: a simple looking-glass waggled in the hand will suffice to spread out the spark into a serrated band, just as can be done with a singing or a sensitive flame, a band, too, of very much the same appearance.

Using an ordinary four-square rotating mirror driven electromagnetically at the rate of some two or three revolutions per second, the band is at the lowest pitch seen to be quite coarsely serrated; and fine serrations can be seen with four revolutions per second in even the shrill whistling sparks.

The only difficulty in seeing these effects is to catch them at the right moment. They are only visible for a minute fraction of a revolution, though the band may appear drawn out to some length. The further away a spark is from the mirror, the more drawn out it is, but also the less chance there is of catching it.

With a single observer it is easy to arrange a contact maker on the axle of the mirror which shall bring on the discharge at the right place in the revolution, and the observer may then conveniently watch for the image in a telescope or opera-glass, though at the lower pitches nothing of the kind is necessary.

But to show it to a large audience various plans can be adopted. One is to arrange for several sparks instead of one; another is to multiply images of a single spark by suitably adjusted reflectors, which if they are concave will give magnified images; another is to use several rotating mirrors; and, indeed, I do use two, one adjusted so as to suit the spectators in the gallery.

But the best plan that has struck me is to combine an intermittent and an oscillatory discharge. Have the circuit in two branches, one of high resistance so as to give intermittences, the other of ordinary resistance so as to be oscillatory, and let the mirror analyse every constituent of the intermittent discharge into a serrated band. There will thus be not one spark, but a multitude of successive sparks, close enough together to sound almost like one, separate enough in the rotating mirror to be visible on all sides at once, and each one analysed into a serrated band.

But to achieve it one must have great exciting power. In spite of the power of this magnificent Wimshurst machine, it takes some time to charge up our great Leyden battery, and it is tedious waiting for each spark. For a single observer it does excellently; for a number of observers one wants an instrument which shall charge the battery not once only, but many times over, with overflows between, and all in the twinkling of an eye.

To get this I must abandon my friend Mr. Wimshurst, and return to Michael Faraday. In front of the table is a great induction coil; its secondary has the resistance needed to give an intermittent discharge. The quantity it supplies at a single spark will fill our jar to overflowing several times over. [Excite jars by coil.]

Running over the gamut with this coil now used as our exciter instead of the Wimshurst machine—everything else remaining exactly as it was—you hear the sparks give the same notes as before, but with a slight rattle in addition, indicating intermittence as well as alternation. Rotate the mirror, and every one should see one or other of the serrated bands of light at nearly every break of the primary current of the coil. [Rotating mirror to analyse sparks.]

The musical sparks which I have now shown you were obtained by me during a special digression* for the purpose while examining the effect of discharging a Leyden jar round heavy glass or bisulphide of carbon. The rotation of the plane of polarisation of light by a steady current, or by a magnetic field of any kind properly disposed with respect to the rays of light, is a very familiar one in

* During this experiment the audience observed the gilding of the paper brightly sparkling on the walls of the room. It was probably the primary result of the absorption of the electric waves. When light falls on metal it excites electric currents and is reflected. The large waves of electric radiation with which the room was full during the discharge of the jar excited visible electric currents in the act of being reflected by the gilt walls. It is the same kind of thing as in other forms I have often noticed in connection with lighting conductor experiments, and is only another illustration of the danger attending the best conductors as ordinarily arranged. It was this kind of splashing or surging of electricity which recently set on fire the Hotel de Ville at Brussels, so elaborately and exceptionally well protected by M. Melsens. This suggested explanation is merely tentative and temporary. I have had no time to investigate the matter locally.

* A conversation with Sir W. Thomson at Christmas had probably something to do with my seeing the interest of getting slow oscillations. My chief attention has been directed to quick oscillations.

Digitized by Google

this place. Perhaps it is known also that it can be done by a Leyden jar current. But I do not think it is; and the fact seems to me very interesting. It is not exactly new—in fact, as things go now it may be almost called old, for it was investigated six or seven years ago by two most highly skilled French experimenters, Messrs. Bichat and Blondlot.

But it is exceedingly interesting as showing how short a time, how absolutely no time is needed by heavy glass to throw itself into the suitable rotatory condition. Some observers have thought they had proved that heavy glass requires time to develop the effect, by spinning it between the poles of a magnet and seeing the effect decrease; but their conclusions cannot be right, for the polarised light follows every oscillation in the discharge, the plane of polarisation being waved to and fro as often as 70,000 times a second in my own observation.

Very few persons in the world have seen the effect. In fact, I doubt if anyone had seen it a month ago except Messrs. Bichat and Blondlot. But I hope to make it visible to most persons here, though I hardly hope to make it visible to all.

Returning to the Wimshurst machine as exciter, I pass a discharge round the spiral of wire inclosing this long tube of CS_2, and the analysing Nicol being turned to darkness, there may be seen a faint—by those close to not so faint, but a very momentary—restoration of light on the screen at every spark. [CS_2 tube experiment on screen.]

Now I say that this light restoration is also oscillatory. One way of proving this fact is to insert a bi-quartz between the Nicols. With a steady current it constitutes a sensitive detector of rotation, its sensitive tint turning green on one side and red on the other. But with this oscillatory current a bi-quartz does absolutely nothing. [Bi-quartz.]

That is one proof. Another is that rotating the analyser either way weakens the extra brightening of the field, and weakens it equally either way.

But the most convincing proof is to reflect the light coming through the tube upon our rotating mirror, and to look now not at the spark, or not only at the spark, but at the faint band into which the last residue of light coming through polariser and tube and analyser is drawn out. [Analyse the light in rotating mirror.]

At every discharge this faint streak brightens in places into a beaded band: these are the oscillations of the polarised light; and when examined side by side they are as absolutely synchronous with the oscillations of the spark itself as can be perceived.

Out of a multitude of phenomena connected with the Leyden jar discharge I have selected a few only to present to you here this evening. Many more might have been shown, and great numbers more are not at present adapted for presentation to an audience, being only visible with difficulty and close to.

An old and trite subject is seen to have in the light of theory an unexpected charm and brilliancy. So it is with a great number of other old familiar facts at the present time.

The present is an epoch of astounding activity in physical science. Progress is a thing of months and weeks, almost of days. The long line of isolated ripples of past discovery seem blending into a mighty wave, on the crest of which one begins to discern some oncoming magnificent generalisation. The suspense is becoming feverish, at times almost painful. One feels like a boy who has been long strumming on the silent key-board of a deserted organ, into the chest of which an unseen power begins to blow a vivifying breath. Astonished, he now finds that the touch of a finger elicits a responsive note, and he hesitates, half delighted, half affrighted, lest he be deafened by the chords which it would seem he can now summon forth almost at will.

ARC LAMPS AND THEIR MECHANISM.*

BY PROF. SILVANUS P. THOMPSON, D.SC., M.I.E.E.

An arc lamp being an apparatus for transforming the electric energy supplied to it through the conducting wires into heat and light, it obviously cannot be expected to give a steady illumination unless it can be so arranged and operated that, in the first place, the rate at which it appropriates and transforms the electric energy is constant; and that, in the second place, the circumstances attending this transformation (in respect of the triple relation between the quantity of heat evolved, the degree of temperature, and the emissivity of the incandescent surface) also remain constant. The first of these two provisos relates to the operation of the system of lamps and dynamos (or other means of electric supply) acting conjointly; the second of them relates solely to the quality of the carbon pencils used as electrodes.

As the latter is a simple matter, it may be disposed of first. Suppose the pencils to be composed of a homogeneous carbon, the physical properties of which, such as hardness, specific thermal capacity, conductivity for electricity, conductivity for heat, emissivity, &c., are constant; also that they are cylindrical and of given diameter. Then it follows that if energy is being expended at a uniform rate in heating the tips of a pencil it will be maintained at a uniform temperature, and the amount of light emitted per square millimetre of the surface will be constant, and, as the section is constant, the rate of consumption constant, and the pencil homogeneous, the form once acquired by the incandescent tip (whether positive crater or negative peak) will remain constant. It may be remarked, in passing, that the researches of Capt. Abney have shown that the white light of the incandescent carbon surface of the crater at the positive pole of the arc is always of precisely the same composition in respect of the relative proportions of waves of different colours. This most important observation indicates beyond doubt that the temperature of the actual light-emitting surface is always the same. Indeed, this ought to be the case if the latent heat of vapourisation of carbon be a positive quantity. When the surface attains this temperature volatilisation begins; and when so begun the temperature cannot rise further, any more than ice can be raised above its temperature of fusion. The limiting temperature of the voltaic arc is the temperature of volatilisation of the material of the electrodes. This is, in itself, a reason why the introduction of all known foreign substances whatsoever into the carbon pencils of the arc is found to lower its intrinsic brilliancy; for all known elements have a lower temperature of volatilisation, and all compounds are dissociated at arc temperatures.

If, then, we may assume homogeneity of the carbons to be used the steadiness of the arc light will depend solely upon the maintenance of a steady rate of appropriating and transforming electric energy. How a want of homogeneity may be compensated for in the actual working of the lamp is a point reserved for consideration later.

The rate at which electric energy is appropriated from the wires, and transformed in the lamp into heat and light, always depends both upon the construction of the lamp and upon the conditions imposed upon the system of electric supply. This is a mere consequence of the fact, well known to every electric engineer, that the amount of electric energy per second appropriated by any electric device, motor, or accumulator, is itself the product of two quantities—the current, and the pressure (or potential) at which the current is supplied. To put the matter in electrician's language, the number of *watts* of electric energy per second appropriated by the lamp* is equal to the number of *amperes* that flow through

* Paper read before the Society of Arts on March 6. 1889.

* Strictly speaking, the actual number of *watts* utilised in the arc is somewhat less than the whole number received from the supply, as a portion of the energy is expended in passing the current through the regulating coils, and another portion is lost in consequence of the resistance offered by the pencils of carbon themselves, and is merely expended in warming them. We may calculate the former loss as follows:—Let E represent the whole number of volts from terminal to terminal, and let i represent the whole current supplied, then the whole number of watts supplied is Ei. Let the *ohms* of resistance of the regulating coils in the main circuit be called a, and that of the shunt coils be called b, that of the carbon pencils themselves c, and that of the resistance coils sometimes used in the main circuit to steady the arc r. Also, in the case where the lamp has a shunt circuit, let the portion of i which passes through the carbons be called i_1, and that which goes through the shunt i_2; so that $i_1 + i_2 = i$. The losses are then as follows:—

ai_1^2 = watts lost in main-circuit coil;
bi_2^2 = $E^2 \div b$ = watts lost in shunt coil;
ci_1^2 = watts lost in warming carbon pencil;
ri^2 = watts lost in the resistance coil.

The resistance of carbon pencils is usually small, and may be materially reduced by a thin coating of copper. The carbons used in commerce (11 to 15 millimetres in diameter) vary from about 0·15 to 0·2 ohms per foot, if plain, and from 0·001 to 0·09 if coppered. Cored carbons have a higher resistance than uncored. Carbons cut from solid gas coke have from five to twenty times as much resistance as those made by the usual modern processes. When lamps are run in series, the resistance offered by the pencils is of more importance; for example, a set of 50 lamps newly trimmed with long carbons may offer 25 ohms more resistance than when all the carbons have burned down short. The resistance, a, of the regulating coils that are in the main circuit differs in different lamps, but may be taken at from 0·05 to 0·2 ohms. The resistance, b, of the shunt coils is seldom less than 200 ohms, and may be as much as from 400 to 500 ohms. Of the volts, E, applied to the lamp only a part is utilised, the lost volts being accounted for by the resistances in the path of the current. If these are deducted from the applied electromotive force, there will remain a certain number of volts, which we may call e, which are available as a useful difference of potential at the arc itself. To measure e directly, one has only to apply a voltmeter, making the contacts of its two leading wires to the two carbons at points respectively just above and just below the incandescent tips. The watts actually utilised in the arc are then calculated as the product ei_1. As shown above, e is less than E, and, indeed, may be considerably less, the lost volts depending upon the resistances introduced, and on the current flowing through them. If E is constant, e will not necessarily be so, but will be very nearly if i is also constant. Also i_1 is less than i in all lamps that have a shunt regulating coil, but is not usually more than from 3 to 5 per cent. less than i, so that in the cases where i is kept constant, i_1 will be nearly so also.

Digitized by Google

it multiplied by the number of *volts* that may be applied as a difference of potentials between its two terminals. To keep constant the *product* of the amperes and the volts is the practical problem which the mechanism of the arc lamp must be designed to solve.

A point of much theoretical interest, and in reality of great practical importance, is the fact, long disputed, now established beyond question, that the arc itself does not act simply as an added resistance in the path of the current, but exercises also a counter-electromotive force, and tends to set up an opposing current. The apparent resistance of the arc resembles that of an electrolytic cell, or that of an electric motor when running, or, that of a thermopile when a current from an external source is passed through it. The current which flows through the arc arouses, by a species of polarisation, an opposing electromotive force. The simplest fact in proof of this is that, unlike any ordinary conductor, the apparent resistance of the arc is not proportional to its length. The apparent resistance of an arc two millimetres in length between the carbon tips is not double that of an arc one millimetre in length, nor anything near double. The fairest way to investigate the matter is to make a series of experiments with arcs of different lengths, the current being independently so regulated as to be maintained of the same strength in each case. There appears to be a true resistance proportional to the length, and a back-electromotive force which in steady arcs, and with currents of from seven to fifteen amperes, appears to be about 38 to 39 volts. When the arc hisses, as often happens if the length of it be very short, the back-electromotive force fluctuates very much, but always drops to something under 20 volts. Except in the case of constant-current circuits, this causes a sudden increase of current when the lamp begins to hiss, and it may be noticed that the light, though unsteady during hissing, is brighter at the negative pole of the arc.

Hitherto all guesses as to the cause of this counter-electromotive force have been very vague, not to say wild. To account for thirty-nine volts of polarisation on any hypothesis that it is due to electrolytic or thermo-electric action, is to suggest causes which are, to say the least, wholly inadequate. The explanation which for the past two years I have been in the habit of suggesting to my students, and which has not been otherwise published hitherto, is as follows:—Every reversible phenomenon which the current can itself produce, and which requires an expenditure of energy for its production, necessarily implies the exhibition of a counter-electromotive force. One has only to look at the cases of the reversible chemical action in a cell, of the reversible magneto-mechanical action of a motor, the reversible heating effects of a thermo-electric junction, to comprehend this. Now the phenomenon of volatilisation is a reversible one; give to the solid carbon at its volatilisation-temperature the necessary latent heat, it is changed to vapour; take from the vapour its latent heat, it condenses back to solid carbon. The arc under normal circumstances is the seat of an actual evaporation of carbon at the positive pole, as well as of a combustion at both poles. So far as any data exist, it appears that the excess of carbon consumed at the positive pole by an ordinary continuous current is about 0·5 grammes per ampere hour. If we knew the latent heat of volatilisation of carbon per gramme we could calculate *à priori* the necessary minimum electromotive force at the positive pole, which would obviously represent the counter-electromotive force so far as it is situated at that point. With long arcs the excess of consumption of the positive pencil over that of the negative is both less and more regular than that which occurs with short arcs. With short arcs three other phenomena occur which are important in this connection. Firstly, the short arc is liable to whistle or hiss, giving evidence of instability; secondly, it frequently gives rise to "mushrooms," or irregular growths of carbon upon the apex of the negative pencil; thirdly, when it hisses the counter-electromotive force becomes very unsteady, but appears to have an average value about half that of the steady long arc. It is worth while to throw out the suggestion that the condensation of carbon at the negative pole, in the short arc is accountable for the change in electromotive force, and for the instability which manifests itself by the hissing sound.

Passing from these conjectures to the construction of lamps for the production of light by the arc, we are now prepared to lay down the points which must be provided for in every arc lamp. It must be emphatically pointed out at the outset that, as the performance of a lamp depends upon the conditions under which it is supplied with electric energy by the circuit, the design of the lamp necessarily also depends on those conditions. In the present state of the art of electric distribution we may classify the conditions of electric supply under the following heads:—

I.—Continuous Supply at Constant Potential.

In this case the arc lamps are arranged either simply all in parallel or in parallels containing two in series, the currents being divided by mains and branches to the lamps. At least 55 volts should be allowed between the mains for single arcs. Practice shows that arc lamps in parallel burn more steadily if a resistance wire of ·25 to 1·0 ohm be included in the lamp circuit. Taking the back electromotive force of a steady arc at 39 volts, it is obvious that the excess of the volts at the mains over this represents the volts used in driving the current through the actual resistance in the main circuit of the lamp. This resistance consists of four parts—the true resistance of the arc itself, which may vary from $\frac{1}{10}$ to $\frac{1}{2}$ ohm; the resistance of the carbon pencils, which averages about 0·15 ohm per foot per plain carbons; the resistance of the main-circuit coils, which varies in different lamps from 0·05 to 0·2 ohm; and the resistance of the wire introduced for steadying the lamp. In a 10-ampere lamp, working at 55 volts at the mains, 16 volts remain, after deducting 39 for the back electromotive force, and these 16 are approximately distributed as follows:—2 volts in the arc itself, 3 volts in the carbons (say 2ft. long in the total), 1 volt in the main coil, and 10 volts in the steadying resistance.

II.—Continuous Supply with Constant Current.

In this case the arc lamps arranged in series, the whole of the current going from one lamp to the next, and returning to the dynamo after having traversed successively all the lamps. This is, *par excellence*, the arc light system of distribution, the parallel system at constant potential requiring heavier mains. As the lamps arranged in series tend to steady one another, it is not necessary to allow more than 45 to 50 volts per lamp, including the ordinary lengths of cable from lamp to lamp. From 5 to 10 amperes is the usual current for arc lamps in series.

III.—Alternating Supply at Constant Potential.

In this case also the lamps are usually arranged as in the first case, the only difference being in certain structural details, such as lamination of iron cores.

IV.—Alternating Supply with Constant Current.

This case can hardly be said to be practical, though alternate-current dynamos, capable of supplying 6 or 8 lamps in series, have been constructed in past years.

The supply systems, whether continuous or alternating, must be assumed, for the purpose of this Paper, to perform efficiently what they profess, namely, to maintain constant one of the two factors of the electric power which they supply to the distributing system. In each case it remains for the mechanism of the lamp to effect such adjustment as will maintain constant the other factor of the product. If the condition of supply is at constant potential, then it is for the lamp itself so to adjust its carbons as to keep the current through the arc constant. If the condition of supply is with constant current, then the lamp must adjust it carbons to maintain between them the requisite potential. Hence the differences which are necessary in construction between those lamps which are to work at constant potential and those which are to work with constant current. These differences, as will now be shown, chiefly affect the feeding mechanisms of the lamp.

In discussing the necessary mechanisms of arc lamps, no further reference will be made to lamps of the Jablochkoff candle type, nor to those with abutment blocks of marble ("Sun" lamp, &c.), nor to the so-called incandescence-arc ("Semi-incandescent") lamps, nor to those with curved carbons (Heinrichs's type), nor yet to those horizontal carbons (De Mersenne's, Solignac's, &c.).

Necessary Mechanism of Arc Lamps.

[A]. *Driving Power.*—In every lamp some means or mechanism is required to propel the carbons toward one another as they burn away, gravity being by far the most common agency for doing this.

[B.] *Striking Mechanism.*—In every arc lamp it is requisite to provide a mechanism for bringing the tips of the carbon pencils into contact, and then parting them asunder to the requisite distance across which the arc or flame plays. If, as in most lamps, the carbons are in contact when the lamp is out of action, then a mechanism is required simply to part them as soon as the current is turned on. The operation of producing the arc by parting the carbons is known as "striking" the arc. The mechanism must be automatic, so as to come into action not only when the current is first turned on, but at any subsequent time if from any cause the arc fails. An adjustment, *b*, of the striking mechanism is also usually added to permit of regulation in the length of the stroke or initial distance between the poles.

[C.] *Feeding Mechanism.*—As the carbons burn away, one or both of them must be propelled forward to maintain the arc at its proper size. This action is called "feeding" the arc. This action ought to take place by small and imperceptible amounts, and as the rate of consumption of the carbons is continually varying, even with carbons of the best modern manufacture, the lamp must itself regulate the rate at which the pencils are propelled forward in automatic correspondence with the consumption for the time being. Further, since the presence of soft and more readily volatilised portions in the pencils seems to be unavoidable, provision ought to be made, so that whenever the pencil

Digitized by Google

burns down to such a portion, causing a sudden increase in the volume of the flame or arc—technically called a "blower"—the mechanism of the lamp ought at once automatically to draw apart the pencils to a slightly greater distance. A lamp which has a *retractile* motion in either its feeding or its striking mechanism is superior to one that has not, as it can be used with cheaper and less pure brands of carbons. An adjustment, *c*, for regulating the frequency or range or the feeding movements is usual.

[D.] *Replacement Mechanism.*—When the pair of carbon pencils has burned away, the lamp trimmer has to replace the stumps by a new pair of long carbons. In order to admit these, the carbon holders must be pushed apart to their widest extent. Special mechanical devices for allowing this motion to occur have to be provided in some forms of lamp, whilst other forms need no special device.

[E.] *Moderating Mechanism.*—To prevent the carbon from making too sudden motions, it is usual to add a moderating device, such as a dash-pot, or, in the case of those lamps in which there is a train of wheels, a fan or a governor.

So far, the devices enumerated have been such as are common to all classes of lamps. Those which follow are only required in particular types of lamp.

[F.] *Focussing Mechanism.*—In all those cases where it is desired that the luminous points should occupy a fixed position in space, some additional mechanism is necessary to make the arc lamp keep its focus. In lamps designed for the mere lighting of area, this is not important, and in the vast majority of these the upper carbon descends whilst the lower carbon (the negative) is fixed, the luminous point slowly shifting downwards as the carbons consume. All devices for causing the carbons to move forward at such relative rates as to keep an approximately fixed position for the arc will be discussed, together with their methods of adjustment, *f*, under the heading of focussing mechanism.

[G.] *Change-over Mechanism.*—Lamps that must run for many hours continuously must be supplied with two pairs of pencils, because it is neither practicable nor advisable to use pencils of extreme length. In the double lamps it is appropriate to provide such arrangements as shall cause one pair of pencils to come into operation first, and when these are consumed away shall change over the action, either by electrical or by mechanical devices, so that the second pair of pencils shall come into operation.

[H.] *Cut-out Mechanism.*—Lamps intended for series working must be provided with some contrivance to prevent the extinction of the whole series when from any cause there is a failure of the light in any one lamp. The usual device is a sort of automatic relay arranged in connection with each lamp, to come into operation in the event of its failure, the operation of the device being (1) to cut the faulty lamp out of circuit by simply short-circuiting it, or (2) to substitute for it a wire of suitable resistance, or (3) to replace it by an auxiliary lamp. The device for performing either of the two former operations is technically known as a "cut-out."

Supplementary Contrivances.

In addition to the eight distinct species of contrivances above enumerated, there are numerous details which might be further classified; such, for example, as devices for *clamping* the carbon pencils to their respective holders in true allignment; devices for raising and lowering the lamps. For these, however, there is no space. Neither is it possible to enumerate the devices which have been suggested [Staite, Siemens, Brockie, Andrews, Crompton, Swinburne and others] for *compensating*, in lamps whose action depends on the weight of the descending carbon pencil and its holder, for the diminution of pull as the pencil is consumed.

Schedule of Mechanisms.

A schedule embracing the eight heads above enumerated, if supplemented by statements of the gauges and resistances of the wires used in the windings of the coils, affords a systematic and very convenient method of tabulating the facts concerning the construction of any arc lamp. An example of such schedule, filled up with the data of one arc lamp of recent pattern, will be given at the end of this Paper.

Electro-magnets for Arc Lamps.

As the electro-magnet plays so essential a part in the striking, feeding, and cut-out mechanisms of lamps, a short digression upon the particular forms of electro-magnets appropriate to arc lamps is not out of place. The ordinary treatises on electricity have little to tell about the special properties of different forms of electro-magnet; indeed, this all-important organ in modern electrical engineering has received very inadequate attention from writers on electricity. It is a familiar fact that the attraction of a horseshoe-shaped magnet, whether of steel or iron, varies very greatly with the position of the iron armature, being great at small distances, but very rapidly falling away as the intervening space is increased. To devise a form of electromagnet whose attractive power shall be exerted over a fairly long range was at one time one of the practical problems of electricians, and it has been solved in various ways. The attraction which a solenoid, or tubular coil, exerts, when traversed by a current, upon an iron core introduced within its aperture, is not, in any position of the core, nearly as great as that exercised by an electromagnet of horseshoe type, constructed of equal amounts of metal, and energised by an equal current. On the other hand, the feebler pull of the solenoid upon its core is exerted through a very extended range. And by making the core of conical form, or by winding the coils of the solenoid in a conical fashion, it is possible still more completely to equalise the pull over a long range. Solenoids with cores are used in several well-known types of lamps in which a long travel is required. On the other hand, since the operation of striking the arc requires a short motion not exceeding one-twelfth of an inch, or two millimetres, in all those types of lamp in which a special electro-magnet is used simply to strike the arc, a form of electro-magnet is required which will exert a powerful pull over a short range. Further, for working certain clutch mechanisms and the like, it is desirable that a form of electro-magnet should be

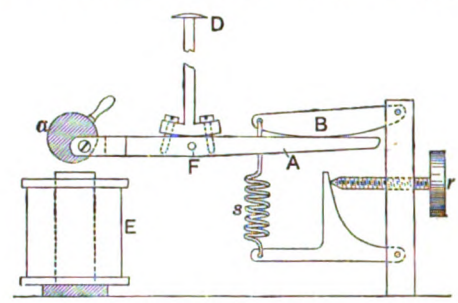


Fig. 1.—Houdin's Equaliser.

found which, whilst having a travel of, say, one inch, should exert throughout the whole of that range a fairly strong pull, increasing, of course, toward the end. Experiments show that the special forms of electro-magnet may be tabulated as follows:—

(*a*) *Short-range Magnets.*—1. Horseshoe form, if constructed with short thick cores, thick yoke and thick armature, giving compact magnetic circuit.

2. "Pot-magnet," straight core with external tubular envelope, connected by iron at bottom. Armature, a stout iron disc or lid.

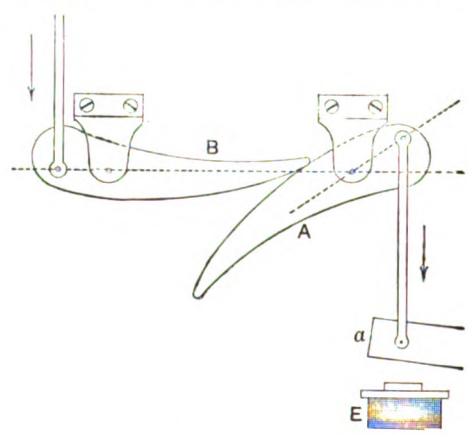

Fig. 2.—Foucault's Equaliser.

(*b*) *Moderate-range Magnets.*—1. Horseshoe form with long thin cores and armature, giving a non-compact circuit.

2. Solenoid having a short fixed core extending part of the way down, and a second movable core to be attracted in as plunger. The name "stopped solenoid" is suggested as appropriate for this form.

3. Two such as last, having a yoke connecting the two fixed cores, and a second yoke connecting movable cores.

4. Stopped solenoid with plunger attached to an outer mantle [Kennedy's lamp].

5. Electromagnet with conical poles protruding through hollow in armature [Thomson-Houston lamps].

6. Electromagnets with oblique approach of armature [Serrin's; De Puydt's; and many other lamps].

(*c*) *Long-range Magnets.*—1. Solenoid, cylindrical, with longer cylindrical core. Attraction greatest when entrant end of core just reaches the further side.

2. Solenoid, cylindrical, with long coned core entering with the point foremost.

Digitized by Google

3. Solenoid, conical, with long cylindrical core entering the thicker end of solenoid.

4. Special device for travel of unlimited length. A solenoid constructed in sections, which are switched into circuit progressively ahead of the core as the core travels down.* [Thomas, 578^{82}; Lindemann, 16376^{87}.]

It must be borne in mind that the range of an electromagnet depends on the relative dispositions of the iron parts of the magnetic circuit and of the magnetising copper parts, and in no way upon the question whether the coil consists of a few turns of thick wire, or of many turns of thin wire.

Equalisers.

In sundry forms of lamp special mechanical devices have been introduced for the purpose of equalising, throughout a given range of motion, the otherwise very unequal pull of the electromagnet upon its armature. Set-up springs with adjustable stops have been used for this purpose. A more satisfactory *equaliser (repartiteur)* is the device suggested by the famous conjuror, Robert Houdin, which is depicted in Fig. 1. Here the attraction of the electromagnet, E, for its armature *a*, is transmitted through a system of two curved levers, A and B, which rock on one another at a point of mutual contact which varies the "mechanical advantage" of the system, and partially or wholly, according to the curvature, compensates for the great increase of force as the distance of the armature diminishes.

The form of the equaliser of Foucault, as used in the Foucault-Duboscq lamp, is depicted in Fig. 2. Here the armature, *a*, which is stiffly pivoted eccentrically to allow of adjustment, is attached to a lever, A, whose fulcrum is at F, and the opposing force of a spring, *s* (itself adjustable by the screw *r*) is applied through the curved rocking lever B. The vertical arm attached above F carries the detent D. Equalisers depending on use of a rocking lever are to be found in several lamps. [Serrin's lamp; also Mackenzie, 95^{82}, and Common, 626^{82}.]

Returning from this digression, we have now to go separately over the eight items of the schedule, and point out how the various necessities have been met by the ingenuity of various inventors. As it is impossible to mention all instances of carrying out a principle, reference is made only to a few cases, preferably to the best known lamps

(To be continued.)

LIST OF GERMAN CENTRAL STATIONS.

(PREPARED BY OUR BERLIN CORRESPONDENT.)

Town.	System.	Output in horse-power.	Distribution.
Barmen	Three-wire System (Accumulators)	600	Underground.
Berlin:			
(*a*) Markgrafenstrasse...	Two-wire System	3,900 together	Underground.
(*b*) Mauerstrasse...			
(*c*) Spandauerstrasse*	Three-wire System	2,000	Underground.
(*d*) Dorotheenstrasse*	Three-wire System	2,000	Underground.
Braunscharig*	—	—	—
Bremen*	Three-wire System	600	—
Breslau*	—	500	Underground.
Cologne*	—	—	—
Darmstadt	Three-wire System (Accumulators)	450	Underground.
Dresden*	—	500	—
Eberstadt*	—	100	—
Elberfeld	Three-wire System	325	—
Ems (bathing-place)	200 volts (Multiple series)	100	Overhead.
Frankfort-on-Main*	—	1,000	—
Görlitz*	—	450	—
Halle-on-Saale*	—	550	—
Hamburg	Two-wire System	1,200	Underground.
Königsberg*	—	300	—
Lübeck	Two-wire System	300	Underground.
Magdeburg*	—	500	—
Mühlhausen	Three-wire System	300	Underground.
Olmütz*	—	—	—
Strasburg*	—	400	—

Those marked * are in progress.

From this list it follows that in Germany there exists no central station at all that uses alternating currents; that, generally speaking, the mains and feeders are laid underground; and that for all larger stations the three-wire system is brought into use. From the 16,000 horse-power employed in the German Empire for electric lighting by central stations, exactly one-half are used in Berlin.

* Figures in square brackets relate to patent specification or date.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, March 15th.

Royal Institution.

9 p.m. Evening Discourse. "Beacon Lights and Fog Signals." By Sir James Douglas, F.R.S.

SATURDAY, March 16th.

Royal Institution.

3 p.m. Afternoon Lecture. "Experimental Optics (Polarisation: Wave Theory)." By the Right Hon. Lord Rayleigh, M.A., F.R.S.

MONDAY, March 18th.

Society of Arts.

8 p.m. Cantor Lecture IV., 2. "The Decoration and Illustration of Books." By Walter Crane.

TUESDAY, March 19th.

Royal Institution.

3 p.m. Afternoon Lecture. "Before and After Darwin." By George John Romanes, M.A., F.R.S.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. Discussion on "Indian Railways: the Broad and the Narrow Gauge Systems Contrasted." By F. J. Waring, M.I.C.E. Time permitting, a Paper will be read on "The District Distribution of Steam in the United States." By C. E. Emery, M.I.C.E.

Society of Arts.

8 p.m. Ordinary Meeting. "Objects and Methods of the Society of Arts' Motor Trials." By Prof. A. B. W. Kennedy, F.R.S. The medals awarded at the Society of Arts' Motor Competition will be presented during the evening.

Royal Victoria Hall.

8:30 p.m. Lecture. "The History of a Crime Unravelled by a Piece of Rusting Iron, a Horseshoe and a Match." By Prof. H. E. Armstrong.

WEDNESDAY, March 20th.

Royal Meteorological Society.

7 p.m. Ordinary Meeting. "The Sun: Its Heat and Light." By Dr. W. Marcet, F.R.S. (President).

Civil and Mechanical Engineers' Society.

7 p.m. Ordinary Meeting, at the Westminster Palace Hotel. "The Newmarket Waterworks." By F. Telford.

THURSDAY, March 21st.

Royal Institution.

3 p.m. Afternoon Lecture, "Houses and Their Decoration from Classical to the Mediæval Period." By J. Henry Middleton, M.A.

Institution of Electrical Engineers.

8 p.m. Ordinary Meeting. Paper not decided on.

FRIDAY, March 22nd.

Institution of Civil Engineers.

7:30 p.m. Students' Meeting. "The Cyclical Velocity Fluctuations of Steam and other Engines." By H. B. Ransom, Stud.Inst.C.E.

Royal Institution.

9 p.m. Evening Discourse. "The Science of Animal Locomotion in its Relation to Design in Art." (Illustrated by the zoopraxiscope.) By Eadweard Muybridge.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

EASTERN TELEGRAPH COMPANY.—This company announces the payment on April 15th of a dividend of 3s. per share on the Preference Shares of the company, less income-tax, for the quarter ending March 31st; and an interim dividend of 2s. 6d. per share on the Ordinary Shares of the company, free of income-tax, in respect of profits for the quarter ended December 31st. The register of transfers will be closed from April 8th to 15th, both days inclusive.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

ELECTRICAL BUSINESS IN AMERICA.

The Chicago Convention of the National Electric Light Association, if it has not taught us anything strikingly novel or particularly useful, affords very satisfactory evidence of the growth of electrical industry in the States, and a reasonable prospect of similar progress being made in England—so far, at least, as the dissimilar conditions of the two countries will permit. We are at length starting on more equal terms, and it may be instructive just now to take note of the report which the American Association is able to make, after five years of combined effort, to promote the interests of what, in local parlance, is called "the electrical fraternity." To what extent the Association has contributed to the extraordinary results, the announcement of which was greeted with such enthusiasm at the Chicago meeting last month, is a matter on which we can express no opinion; but if it had done no more than collect and tabulate the statistics which accompany the report, the American Association would have amply justified its existence. The items, in some instances, may be taken as approximate estimates, although the President quotes them with the confidence and precision of a Chancellor of the Exchequer who is about to rate them for the income-tax. But there is no reason to suspect them of exaggeration; and as the totals have been taken year by year for some time past, the comparative rate of progress may be accepted as perfectly trustworthy.

THE ELECTRIC MOTOR AND ITS APPLICATIONS.

By T. C. MARTIN and J. WETZLER.

1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

JUST PUBLISHED. Cloth, 279 pages. 59 Illustrations. Price 10s. 6d. Post Free, 11s.

PRINCIPLES OF DYNAMO ELECTRIC MACHINES.

PRACTICAL DIRECTIONS FOR DESIGNING AND CONSTRUCTING DYNAMOS. With an Appendix containing several articles on Allied Subjects, and a table of Equivalents of Units of Measurement. By CARL HERING.

The above work, just published, is the first American book on Dynamos, and the reputation of the author as a clear, concise writer on the subject of which it treats, is sufficient guarantee of the character of its contents. The book is copiously illustrated, printed on an extra good quality of paper, and neatly and substantially bound.

Turning to these statistics, and confining ourselves to what they reveal of the progress made during 1888-9, we find that, of 5,747 electrical installations believed to be in operation at the beginning of last month only 4,000 were in existence on February 1st, 1888. The actual designation used in the report is "central stations and isolated plants," but whatever these terms may represent, the increase is very remarkable. The President, "figuring in percentages," reckons this an increase for the year of 45·8 per cent., which calculation we do not quite comprehend. Without figuring in percentages, however, we can easily see that, in what follows, the progress indicated is equally gratifying. Arc lamps, which in February, 1888, were estimated as numbering 175,000 in actual use, attained the handsome total of 219,924 at the same date in 1889. A still larger increase, as might be expected, has taken place in the use of incandescent lamps, the number last recorded being 2,504,490, whereas twelve months previously there were only 1,750,000—an increase for the year of more than 750,000. The progress made with electric railroads, including, of course, roads which we should call tramways, is, considering the comparative infancy of this industry, even more striking. During the six months ended February, 1889, for which alone any trustworthy information is obtainable, the number of such railroads has increased from 34 to 53, all of which are now in operation carrying traffic; whilst 44 additional lines are known to be in process of construction. A perhaps more trustworthy proof of their practical application is found in the fact that new cars put upon these lines have in the short period of six months increased from 223 to 378. The mileage in the same period has been augmented by 157½ miles, making the present total single track electric lines in operation 294½ miles; and there are at this moment almost as many miles of line—the exact figures being 273¾ miles—under contract and in course of construction.

Some remarkable figures are given relating to the amount of capital invested in the Electric Light Companies of the United States. We are not told whether this capital is wholly devoted, or to what extent, to electric lighting business; probably like the Association itself, the title in many instances covers the whole field of electrical industry. But be this as it may, from the announcement that fresh capital raised by these companies during the past twelve months amounted to $69,397,734 (equal to about 13 millions sterling) we can form some idea of the strides which electrical business is making on the other side of the Atlantic. The National Electric Light Association of America may well take a sanguine view of its future prospects. Its President is reported to have said that although the Association numbered among its members "every gentleman actively interested in the electrical distribution of light and power, it was an undisputed fact that it ought to include three times that number," and he added, by way of explanation apparently, that "the enormous growth of the industry, and the consequent influx of hundreds of men into its ranks," would lead to a greater increase in the roll of members than there had ever been before. As we may not suspect an American citizen of inventing a class distinction between gentlemen members and men non-members, we can only surmise that he means there is a lot of money to be made by following the fortunes of the Association, and that those men who at present stand aloof have a chance of becoming gentlemen if they step inside. Of course this is mere conjecture; but having regard to the enormous amount of capital being put into the business with which it is identified, we would not be surprised if a very large number of the outside public gradually found it to their interest to join the ranks of the Association.

Some rather lively discussions took place at the meetings which occupied the Convention during its three or four days' sitting. We have only space to refer briefly to what occurred in reference to the "mooted question," or the "live question," as it is variously termed, of underground wires. The Chairman's patience was taxed considerably to keep the "gentlemen" in order whose opposing views or conflicting interests found emphatic expression on that particular topic. Those who had specifics for all the ills which underground wires are heir to were by no means backward in prescribing, whilst those who had wires at present above ground showed a sturdy reluctance to put them on the sick list for purposes of experiment. Our New York contemporary, the *Electrical World*, is glad that the Convention did not declare "the undergrounding of high-tension wires to be entirely feasible," adding the suggestion, equally diplomatic and oracular in its way, that this is a matter that will be "settled as we go." The "underground men," as our contemporary calls them, are, in its opinion, perfectly sincere in their advocacy; and their opponents—daylight men we suppose they must be called—are not less sincere in theirs. Further ventilation is needed; and meanwhile we are to be content with the assurance that "the final solution is neither of to-day nor of to-morrow." On the question of municipalities acquiring electrical undertakings greater unanimity prevailed, there being hardly any criticism on Messrs. FOOTE and WHIPPLE'S contention that neither government nor municipality can engage in commercial business with profit or advantage to the public. There is perhaps something to be said on the other side; but as we have no wish to import into America any of the impending troubles which threaten to embarrass electric lighting industry in this country, we shall discreetly abstain from furnishing arguments to the common enemy.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

SECTION III.—MAGNETIC FIELDS OF COILS AND SOLENOIDS.

(*Continued from page 480.*)

147. *General Character of Field Due to a Solenoid.*—In considering the way to determine the strength of magnetic field

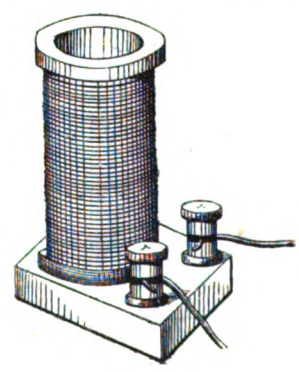

FIG. 139.

at any point on the axis of a ring conductor carrying a current, we gave ourselves a more extended and more general view of the subject than when determining the field at the centre of the coil only. In other words, the latter case is involved in the former, and the student will find it best to master the more general case, because he will then be able to apply it to any special case required. The determination of the field at any point along the axis of a solenoid is the most general case of all, and it will therefore be the last case we shall examine in this section. At the same time, this most general case is the most difficult one to be followed and understood, and the writer

Digitized by Google

hopes, at any rate, to lead up to the final result by a series of easy steps. It will be well here, as previously done, to get a general idea of the character of field exhibited by a solenoid next; to consider the *direction* of the field, and finally its *intensity* in C. G.-S. measure at any point along the axis. This being done, the student will find that he is in a position to intelligently understand the various forms in which galvanometers are constructed. A single low-resistance cell connected to the terminals of a solenoid wound with a few layers of No. 18 or No. 16 double cotton-covered wire will be sufficient to exhibit the general contour of the magnetic field set up in and around the coil. It is better to mount the solenoid on a bit of wood, as in Fig. 139, and carry the two ends of the coil through the wood and along two

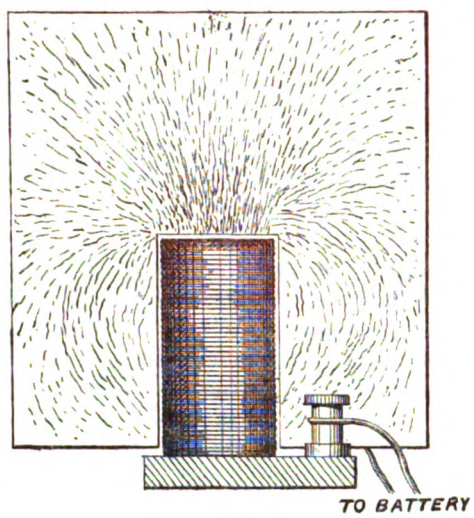

Fig. 140.

slots underneath leading to their terminals. Done in this way you can have two sensible terminals to connect your wires to, instead of the flimsy little terminals sometimes screwed on to the cheek of the bobbin, which frequently cause splitting of the same, or, at all events, make bad contact with the coil.

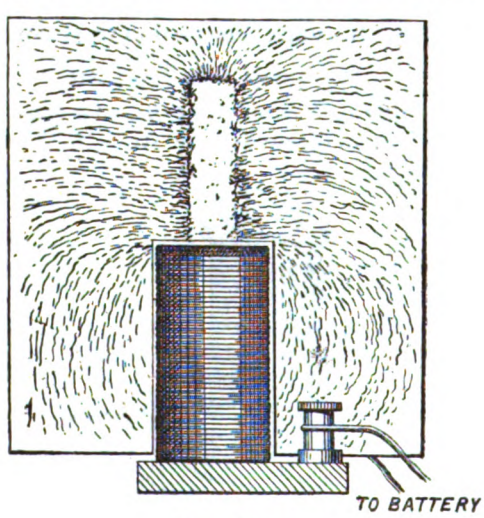

Fig. 141.

After winding, the bobbin may be fixed rigidly to the wooden base by countersinking a hole in the latter deep enough to receive the lower cheek of the bobbin flush with the level of the base. A couple of semi-circular pieces of brass plate covering the cheek and the contiguous part of the base may then be screwed down to the latter, holding the coil firmly in position. Or a piece of brass sheeting may be cut so as to fit over the top cheek and come down in a half-inch strip each side, and be firmly screwed on to the base below. In any case, screws should not be fastened into the cheeks themselves. The solenoid could be fixed horizontally in much the same way on to a base board, but its position will depend on what kind of experiments are to be made with it. When finished, it can be used for a variety of experiments, such as the mechanical pull it exerts upon an iron core to draw it into the coil. This can be varied by trying different kinds of core, such as, for instance, a core built of a bundle of small iron wires and cores of different shapes with pointed and blunt ends, &c., measuring the pull on a spring balance, when, say, a given core has different portions of its length introduced into the coil. The outside layer of wire on the coil should be well brushed over with thick shellac varnish (shellac dissolved in alcohol). This soaks in and hardens the cotton covering, protecting it from abrasion in handling. Curves made from the plotting of the observations above indicated are very useful in showing the action of cores working in solenoids in arc lamps, especially the difference between the pull on a core which moves *with* the carbon rod, as, for instance, in the Pilsen lamp, and that on a core which generally maintains a certain position relative to the coil, as in the Brush or Siemens. The foregoing remarks are merely to indicate what useful experiments and tests may be carried out with a solenoid; to go into detail in this direction would more befit a separate treatise on electric lighting, and is outside our present limits. Taking, then, such a solenoid and laying it down horizontally, we can examine the character of field by iron filings sprinkled on a card supported close to it, as shown (Fig. 140). When the current is on and

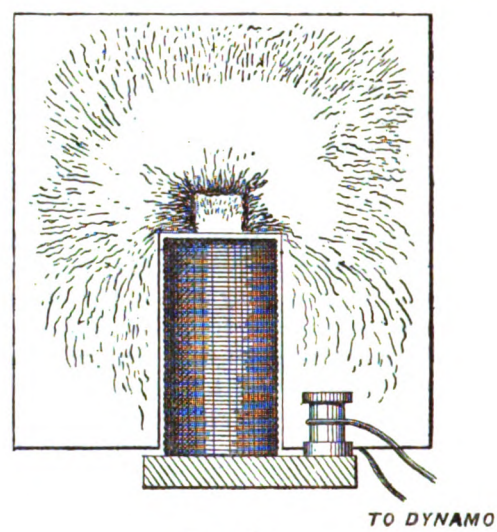

Fig. 142.

the filings are sieved down gently they will be found to arrange themselves as indicated in the figure, and it is easy to see that the solenoid exhibits the same kind of field as a permanent magnet whose length is in the same direction as the length of the solenoid. Further, we can better understand what goes on in the interior of a bar magnet by noticing the kind of field that we get *inside* the solenoid. This is best examined with a small compass needle, which we shall do shortly. Taking an iron core, fitting into the solenoid, and of about the same length, it is interesting to observe that when the core is very nearly out of the coil, as in Fig. 141, the shape of the field is considerably altered. The reason that no iron filings adhere to the card just over the iron core is because the core itself absorbs those lines of force which otherwise would pass through the air and attract the filings. So easy a path does the iron core offer in comparison to the air that the lines pass straight from the interior of the coil into the iron core for some distance before passing outward in the usual curves to complete the magnetic circuit, and this causes the alteration in the shape of the field. The projecting end of the core is strongly magnetised, and its magnetism will be reversed if the direction of current in the coil is reversed. Also, if the core is right inside the solenoid, we have virtually an electro-magnet, and with a direct current we get the same field as we have before shown for electro-magnets. With an alternating current through the coil, however, such a vibration is set up that immediately the filings touch the card the greater part of them dart at once to the core. This effect is shown in Fig. 142.

THE GRAVESEND ELECTRIC TRAMWAY—SERIES SYSTEM.

The tramway line of the Series Electrical Traction Syndicate (Limited), which has just been completed and opened at North-

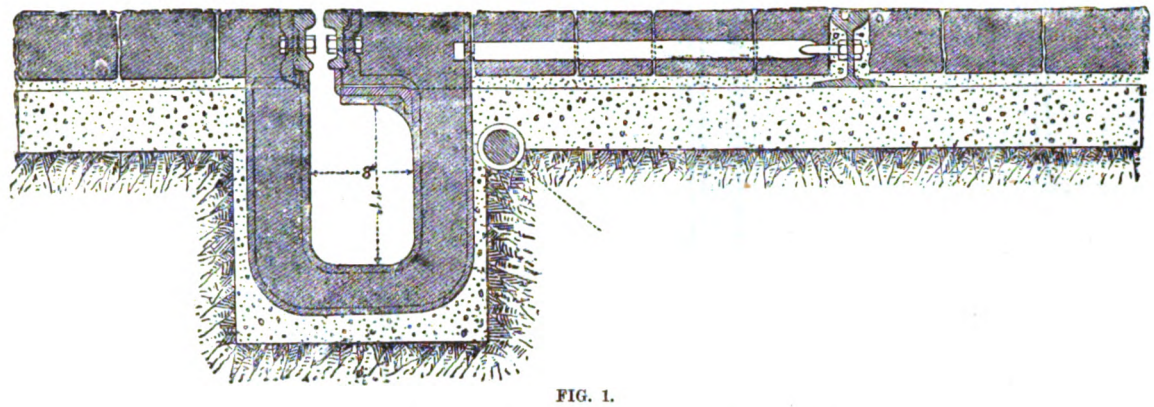

FIG. 1.

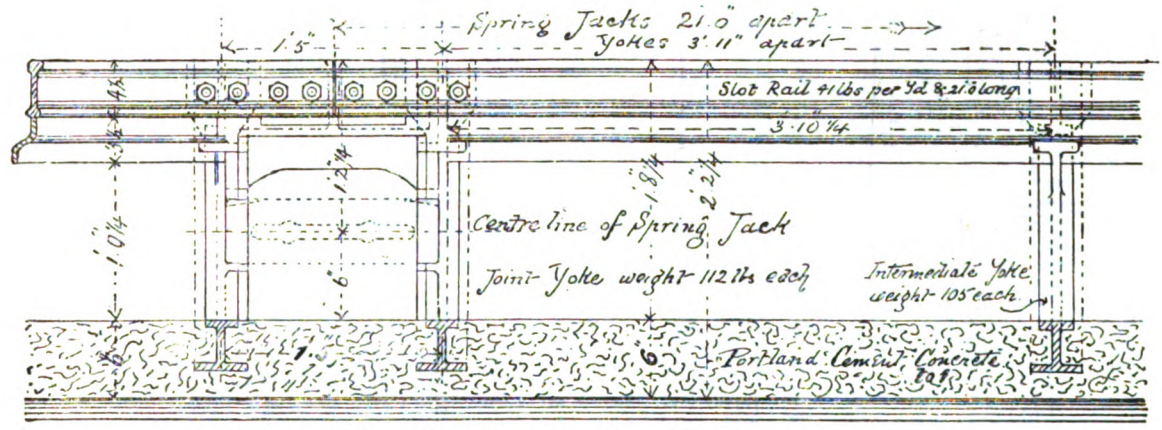

LONGITUDINAL SECTION THROUGH SLOT

FIG. 2.

fleet, has been built chiefly in order to demonstrate the practicability of series working. The importance of the successful working of cars in this manner will be appreciated by all electrical engineers, as removing many difficulties in the way of the application of electricity to large tramway systems by means of parallel distribution. In fact, in electric traction, high tension obviously plays the same *rôle* as in electric lighting, with the difference that, from a purely electrical point of view, constant-current working is much more easily carried out in the former case than in the latter. The Series Traction Syndicate, moreover, claims that it has now successfully overcome all the mechanical difficulties which have arisen in the earlier experiments upon the same system in America.

In order to make this system suitable for adoption in the ordinary roads and streets, the first point to be considered in designing the mechanical details was the construction of such a conduit as would cause the least possible interference with the surface of the roadway, and would be of sufficient structural strength to provide for the heavy traffic of our large towns. In order to avoid a greater interference with the surface of the road than is common to ordinary horse tramways, it was decided in the first instance that the conduit should be laid directly under one of the track-rails, and not, as in the case of cable tramways, centrally to the track. The further consideration of interfering as little as possible with the water and gas mains existing below the surface of the roads required that this conduit should be kept to the smallest possible dimensions consistent with practical working.

The tube, as constructed at Gravesend, is 8in. in width, the bottom being 13in. below the surface of the road. This slot,

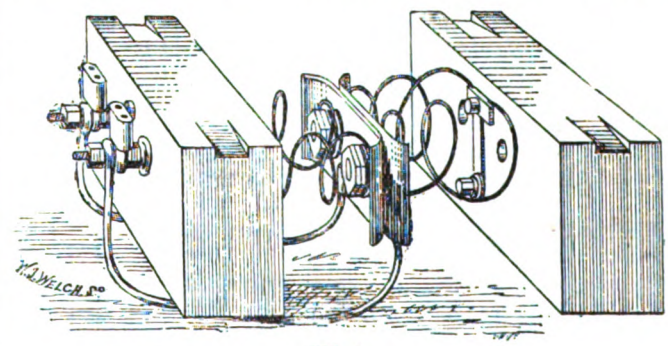

FIG. 3.

through which contact is made between the underground conductor and the car-motor, is formed by leaving a space of $\frac{7}{8}$in.

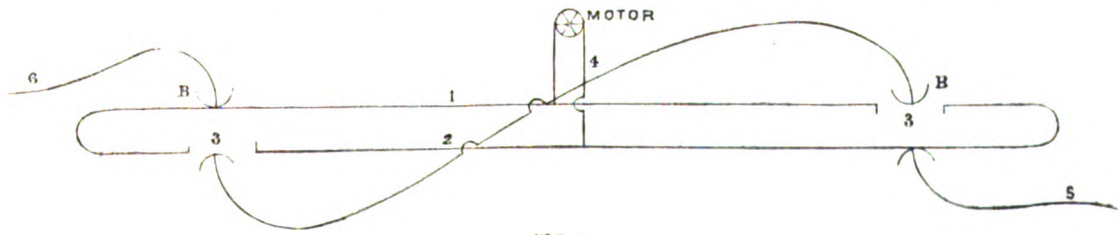

FIG. 4.

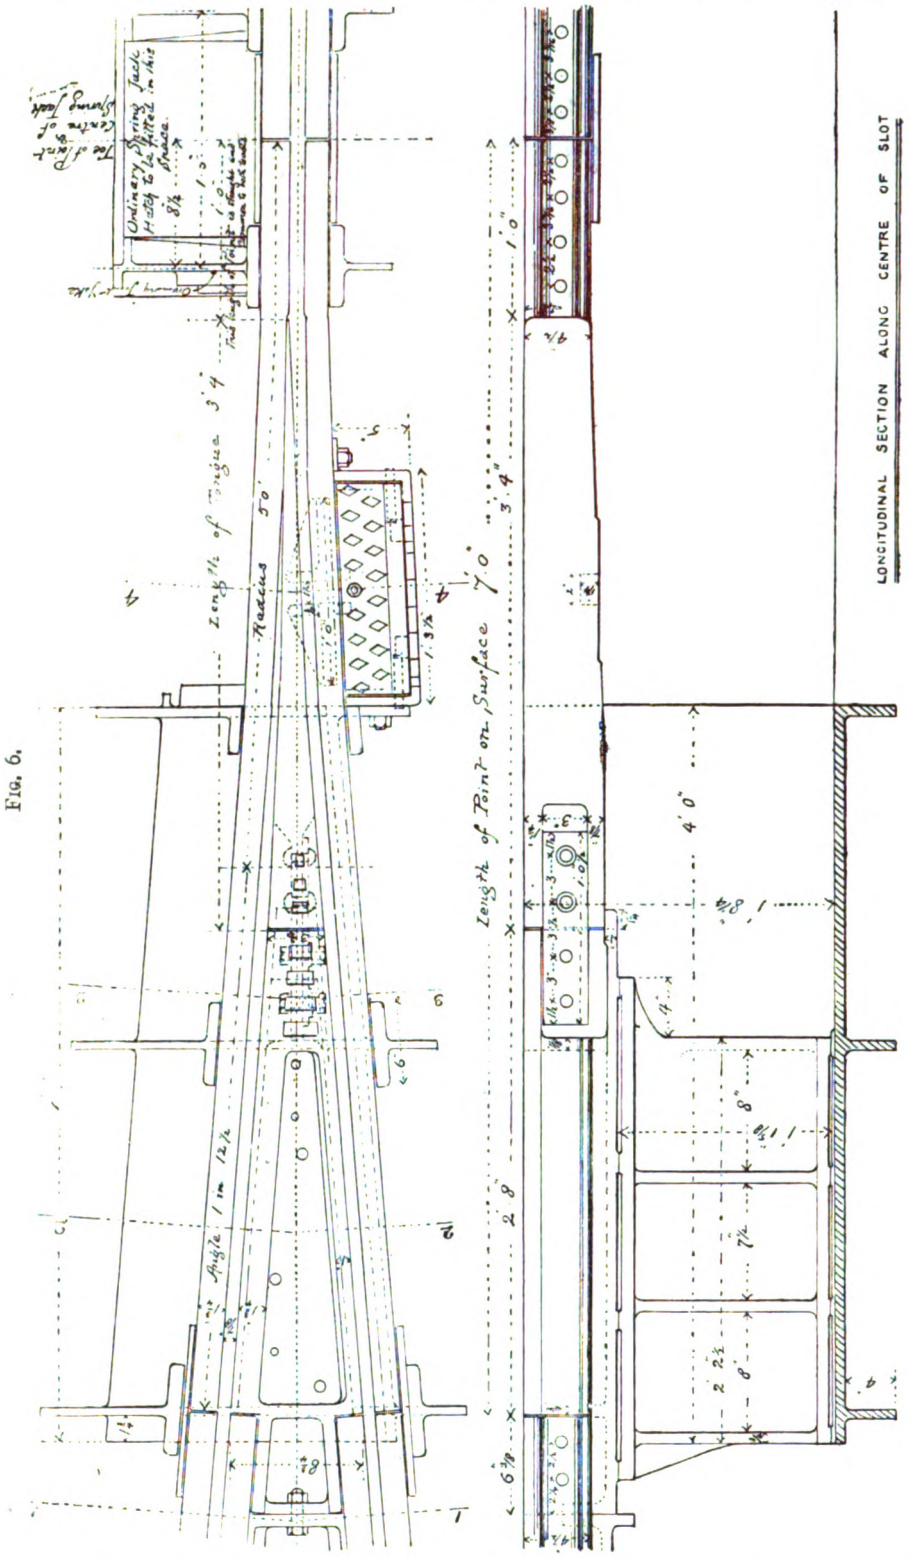
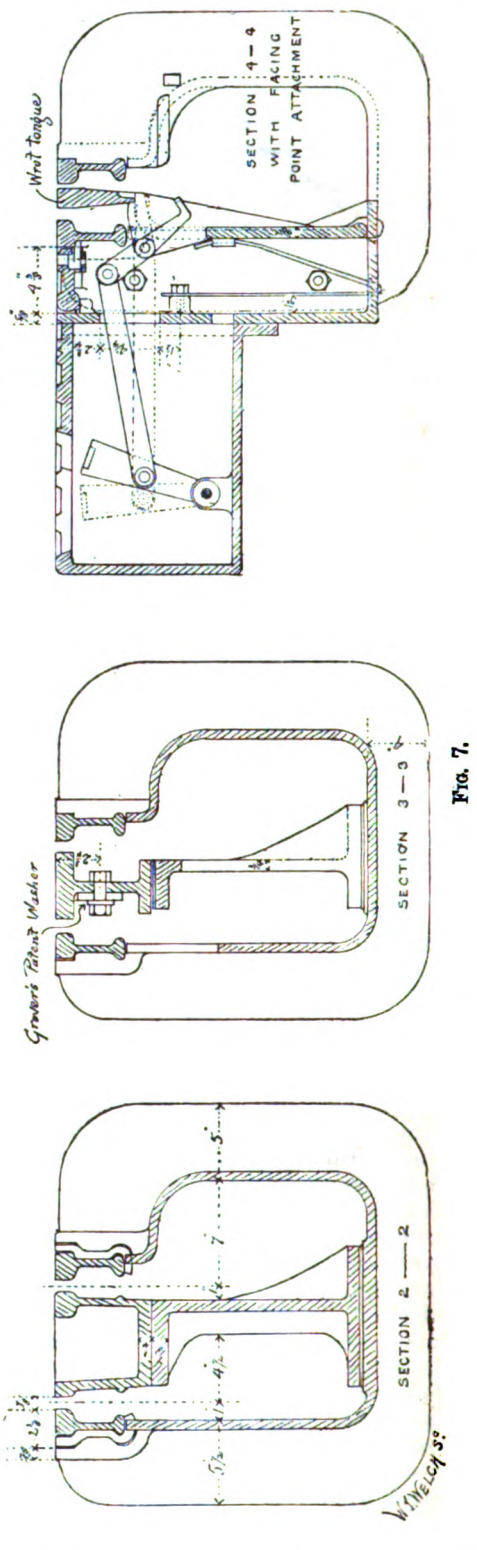
between two bull-headed rails, somewhat similar to the ordinary Vignole's railway rail, these being 4$\frac{1}{2}$in. in depth, with upper flanges 1$\frac{3}{4}$in. wide. The outer of these rails serves as the tread

Digitized by Google

for the tramway wheel, the inner corresponding to the guard-lip of an ordinary tramway rail. These rails are secured through their webs to cast-iron chairs or yokes, at intervals of about 4ft., the yokes being of such section as to leave a clear space below the bottom flange of the rail of 13in. by 8in. The walls of the conduit between the yokes are formed of Portland cement concrete 6in. thick. The rails are laid in lengths of 21ft.; the yokes on either side of the joints being placed 1ft. 5in. apart, centre to centre, and a chamber is formed where these joints occur, covered on the inner side of the rail by a small hatch, 1ft. 4½in. by 8½in., recessed on the surface and filled with wood-paving blocks. These chambers serve for the purpose of access to the "spring-jacks," or contact points, to which reference will be made further on, and also admit of the removal of any dirt which may possibly accumulate in the tube; and, further, give facility for tightening up the fishplates at the rail joints. The corresponding tramway rail is of the ordinary girder type, the gauge being maintained by means of tie-bars attached to the girder rails on the cast-iron yokes, and require no further description. Figs. 1 and 2 show the ordinary construction of the roadway in detail.





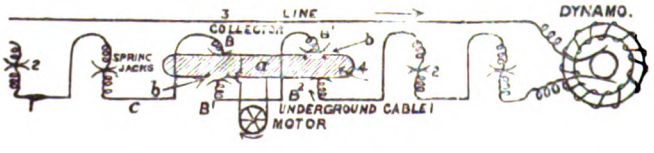


Fig. 5.

Along each side of the track, buried in the concrete, is an earthenware tube 3in. in diameter (*see* Fig. 1), the ends of

Digitized by Google

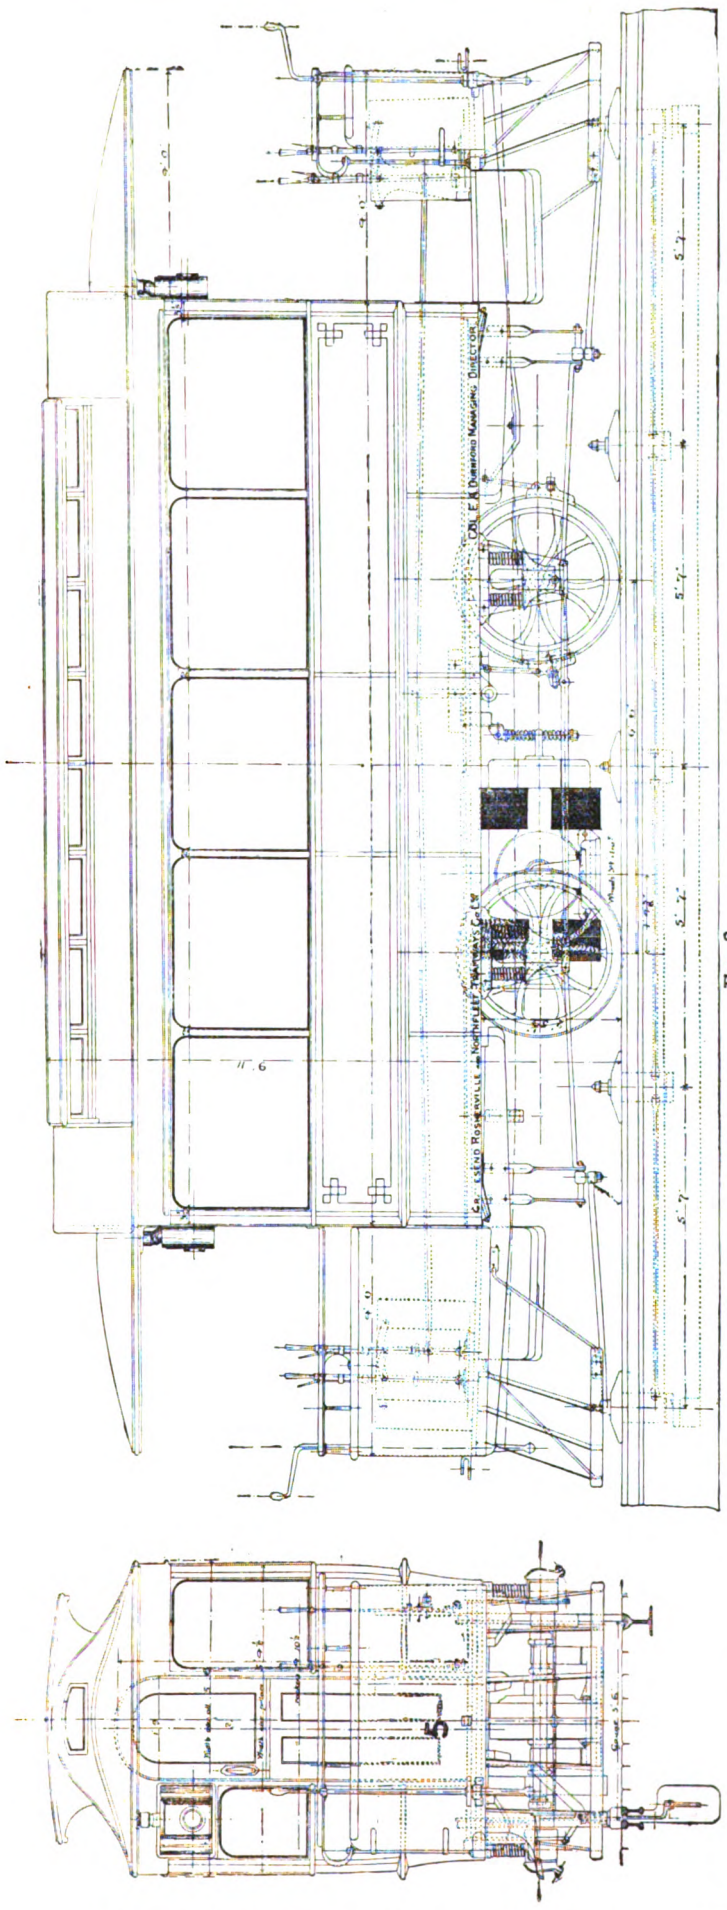

FIG. 8.

which protrude into the cavity formed under the conduit hatches where they are open for access. Into these tubes are drawn lengths of about 21ft. of Henley's ozokerised rubber cable of an insulation resistance of 7,500 megohms per mile, and also the unbroken return cable from the extreme end of the line. These short lengths of highly-insulated cable are the only conductors between the "spring-jacks"—the conduit between these points being only for the passage of the arrow, and, therefore, otherwise empty. In each conduit-chamber is placed a "spring-jack," consisting of a pair of glazed earthenware blocks, 14ft. by 3ft. 4in., supported on brackets, cast on to the joint yokes, the blocks facing each other on opposite sides of the tube. To each block is attached, by means of a double spiral spring, a gun metal casting, curved at the ends, but flat in the centre. The springs are of sufficient strength to press the two castings together with a force of 6lb. The "spring-jack" is shown in Fig. 3. Under the car, and for its full length, is the collector, or the "arrow," which consists of two thicknesses of india-rubber belting, each having a broad brass strip rivetted to it for nearly its entire length. The nose of the arrow at each end is shod with wrought iron brought to a knife edge, so as to easily force its way in between the two faces of the "spring-jack." The maximum thickness of the arrow is 1in., which is consequently the extent to which the gun-metal cheeks are separated. The conductor on each side of the arrow is lapped round one end, and an insulated space is left, slightly greater than the surface of contact of the "spring-jack," near the extreme ends on opposite sides, as will be seen by the diagram, Fig. 4, where 1 and 2 represent the conductors by the insulated gaps and B the "spring-jack" cheeks. With this arrangement it will be seen that in the passage of the arrow from one "spring-jack" to the other, one-half of the "spring-jack" that is being entered, and one-half of the "spring-jack" that is being left, together with the length of cable between them (2), is completely cut out of circuit, the current being, meanwhile, supplied to the motor from the remaining halves of the "spring-jack." It will be readily seen from this that at no moment is the current cut off from the motor, nor is the motor at any moment short-circuited; in fact, the ammeter carried on each car shows the constant value of the current without any variation. Diagram Fig. 5 shows the arrangement of the entire circuit with an arrow passing through the "spring-jacks." The "spring-jacks" themselves are arranged to be taken out or replaced in the conduit in the course of a few minutes. Short-circuiting pieces are provided to enable the continuity of the circuit to be maintained should a "spring-jack" require to be replaced without interrupting the service during the operation, the car easily running by its own momentum through the distance of 21ft., in which it would receive no current. The "spring-jacks" themselves are very simple pieces of apparatus of small cost, and the contact they make by their surfaces being pressed together is excellent, the resistance of the line being but very little higher than that calculated from the direct resistance of the insulated cables themselves. At the turnouts the junction of the conduits underneath the road necessitates the construction of somewhat special points and crossings. The points are provided with movable tongues set so as to automatically direct the traffic to the left hand side of the road, and in order to avoid risk attendant on having a long unsupported tongue forming the roof of the conduits at their junction, a special tumbler has been designed, so formed that it provides a support for the point of the tongue under ordinary conditions, but during the passage of a car it is deflected out of position so as to allow a full clearance for the current collector or "arrow." Where it is necessary, as, for instance, at the terminal fork at the Northfleet Station end of the line, to provide a means by which the cars can be caused to take either track, a claw is pivoted on to the tumbler which can, by means of a lever, be made to engage with the under surface of the tongue, and thus draw it into the required position. Details of the points are shown in Fig. 6, and details of the accompanying crossings where the slot rails cross the girder rail in Fig. 7.

The cars used at Gravesend, which are supplied by the Falcon Engine and Car Works, Loughborough, are shown in Fig. 8. The motors are mounted on the shafts of the car, and are run

Digitized by Google

at 400 revolutions per minute, delivering at this speed, when the field-magnets are fully excited, 15 horse-power on the brake. The motors, which were made by Messrs. Elwell-Parker, are supported in front by two bearings on the driving shaft of the car, the rear being suspended by a spiral spring from the car body. A double helical pinion on the motor shaft drives directly a spur wheel on the car shaft, in the ratio of 1ft. 4½in. This gearing works with great smoothness.

The regulation of the motor is attained by massively-constructed switches mounted on each platform. One switch reverses the connections of the field so as to reverse the direction of the car; the other regulates the resistance of a shunt to the fields, so as to weaken or strengthen it, in proportion to the power required.

One of the cars is lighted electrically by means of low resistance lamps of the Bernstein make. Three accumulator cells, each of 31 plates of the tramway type of the Electrical Power Storage Company, are inserted in the main circuit, and five lamps of 10 amperes each and 65 volts are run in parallel off the accumulators. The accumulators themselves, however, are not discharged; they only serve as potential reducers, the whole of the main current going through the lamps. Should one of the lamps break the remainder are a little more brightly incandesced, and the current due to the broken lamp passes through the accumulator. A two-way switch enables the accumulator to be taken in or out of the main circuit, and the cells are large enough to run all the lamps without assistance from the main current should it be requisite. The arrow is shown in Fig. 8 in position under one side of the car. It is supported at distances of 5ft. 7in. on cast-iron bearing blocks, sliding along the surface of the rail. These blocks are connected with iron tie bars, which take all strain off the india-rubber belt, the whole gear being propelled by the car. It being requisite that current of perfectly constant value should be generated to work the system, the Syndicate selected one of Messrs. Statter and Co.'s constant current machines. This machine fulfils the rather arduous conditions which are imposed upon it perfectly, the E.M.F. being continually varied from a few volts to upwards of 400, the current always remaining constant at 50 amperes. The sparking at the brushes is of the most trifling description, notwithstanding that they are continuously receiving automatic adjustment, sometimes over an arc of 30 degrees. This result is ascribed to the peculiar shaping of the pole pieces.

The generator is driven by a Robey compound underneath type engine of 10 h.p. nom., with locomotive boiler over it.

It will be seen that, in addition to the economy of running obtained by the series system, the manner in which the details are carried out possesses many advantageous features. The highly-insulated cables used over the greater portion of the line, and the comparatively small surface of conductor exposed at the "spring-jacks," may be expected to result in a fairly high insulation throughout. The divided conductor being in very short lengths, a section can be renewed in a very short time without interfering with the traffic of the line; and the conduit being perfectly empty, excepting at the "spring-jack" chambers, is easily cleaned, and can scarcely require taking up at any time. An incipient fault in the line is easily detected and localised by the car-drivers themselves through the ammeters.

The form of the conduit is such that the "spring-jacks" are not directly beneath, the slot being thus protected from road *debris*, in addition to being placed out of danger of interference from the surface, so that even should an "earth" exist it is impossible that a shock should be received through them.

The "spring-jacks," switchgear, lighting, and sundry apparatus have been supplied by the United Electrical Engineering Company (Limited), 3, Prince's-mansions, Westminster.

The whole of the road work and mechanical details were designed by Mr. Joseph Kincard, M.Inst.C.E., the company's consulting engineer, and the construction was executed for him, under the personal supervision of Mr. J. E. Waller, A.M.Inst.C.E., by Messrs. Dick, Kerr and Co.

All the electrical work has been carried out under the supervision of the company's electrical engineer, Mr. E. Manville.

THE AMERICAN NATIONAL ELECTRIC LIGHT ASSOCIATION.

Report of Committee on Underground Conduits and Conductors.

At the meeting of this Association, held at Chicago on Feb. 19, 20, and 21, Mr. E. T. Lynch, jun., read the following report:—

"At the eighth meeting of the National Electric Light Association, held in New York on August 29, 30, and 31, 1888, the following resolution was adopted:—

RESOLVED: "That a committee of five be appointed to examine and report upon the system of underground conduits now in operation, and the number of wires actually in use in these conduits, and to report at the next meeting of this Association."

The president appointed Messrs. Lynch, Barney, Kerr, Davis, and Crocker as members of that committee. And as chairman of that committee, I beg leave to submit the following report:—

As the resolution called for a compilation of all data connected with the actual placing of electrical wires underground, your committee deemed it advisable to send out a circular, calling upon all the local electric light companies for the results of any practical tests that they had made. To carry out this idea, they caused to be printed the following circular:—

"GENTLEMEN: A committee was appointed at the semi-annual Convention of the National Electric Light Association to investigate and collect all data relating to underground wires and conductors, both in this country and Europe. So many erroneous statements have been made from time to time regarding experiments or tests with underground wiring, that the committee feels that it is necessary to obtain all of the most important details and facts regarding this subject.

"Will you, therefore, kindly answer, as far as may be in your power, the following questions, and return the same to the head-quarters of the Association as soon as possible? Your answers to these questions will be looked upon as confidential, and will not be referred to by name or locality in the report of the committee:—

"1. Have you ever placed underground any electric light conductors, carrying currents at a potential of 1,000 volts or over? 2. If so, state the number of experiments, giving the date of each. 3. What was the length of each individual conductor laid underground? 4. What was the voltage on each conductor? 5. What was the current, in amperes, carried by each conductor? 6. What make and style of dynamo supplied the current on each of these conductors? 7. Were these conductors single or grouped in cables? 8. How many conductors to the cable? 9. What was the size of the conductors used? (In answering this question give the number and gauge.) 10. What was the thickness of the insulation? 11. Who was the maker of the cable? 12. Were the cables laid in any form of conduit? 13. If so, what kind of conduit was used? 14. Describe the manner in which the cables were laid in the conduit—whether drawn in, built in, or otherwise. 15. If the cables were laid directly in the ground, describe the method of laying them. 16. Was there more than one duct in the conduit? 17. If there were other ducts what was in them? 18. Did you have exclusive control of the conduit? 19. What was the total duration of your experiments? 20. Did the cables work satisfactorily during the entire time of your experiments? 21. If not, how long did they work satisfactorily? 22. If the cables failed to work satisfactorily, to which of the following causes do you attribute the difficulty? Please answer as fully as possible:—(*a*) Defective insulation; (*b*) defects in joints; (*c*) defects in making connections from cables to lamps."

These were sent to all of the local electric light companies, and in response to them we have received 130 answers. In presenting and compiling the answers to the various questions that were sent out, we have deemed it advisable to divide them into two classes, as follows:—Those who have had actual experience in placing and running underground electric wires and those who have not had actual experience, but whose opinions we have asked. Of the former class there are but seven. We will here give the details of the placing of the wires underground, the duration of tests, style of conduit used, and the general results, that were received in each of these seven answers.

As it was stated in the circular sent out that all the communications would be regarded as strictly confidential, we have deemed it advisable that the names of the companies or individuals should not be mentioned in this report.

First. The writer has used the underground conductors for three years. Has used wire of three of the most prominent manufacturers. Has discarded two and is now using the third. The cables were carried in a cement pipe and manholes were placed at every 250 feet. Cables had been drawn into the conduits, and as a method of facilitating their drawing in, pulverised soapstone had been used for the purpose of avoiding abrasion.

Only one wire placed in each pipe. He states that the wires have not worked satisfactorily, and that he has been compelled to shut down many times, that they are now running fairly well, but he is obliged to keep them under constant supervision and repair. He accounts for most of the trouble that he has experienced by defective insulation, defective mechanical construction, and by deterioration in the insulation in the wires, having had no serious trouble with the style of conduits that he has used. In answer to the question regarding the practicability of placing his conductors underground, he states:—"We are operating some eight miles of underground wire; we wish there were less, and certainly are not anxious for more." In answer to the question regarding the difficulties and objections to underground wiring, and whether he considered them commercial, electrical, or mechanical, he states:—Electrical. There is no cable that will last with a current from a fifty-light dynamo. Commercial—Owing

Digitized by Google

to the large cost of construction and expense of maintenance, and great possibility of breaks, there is consequently poor service and dissatisfaction. He has exclusive control of his conduit.

Second: The writer has made many experiments, in which he has used lengths of cable varying from 200 feet to two miles in length, manufactured by most of the prominent wiring companies. Cables have been laid in and drawn in his own conduits, conduits constructed both of wood and iron. The tests have usually been of short duration, and have been suspended in each case after a failure of the cable to work satisfactorily. The cause of the failure has been mainly defective insulation. Defective mechanical construction, defects in laying, defective conduits, injury to cables in laying or defective joints, have caused very little trouble, the main cause of trouble being in defective insulation and deterioration owing to the presence of gas, water and steam.

His opinion, based upon the results brought out by the many tests that he has made, is that he does not consider it practical at the present time to place conductors underground, the absence of insulation that would stand being the principal reason. If ever that question is settled the cost would, in his estimation, make it commercially impracticable. In only one instance he had the exclusive control of the conduit.

Third: The company represented by the writer had four circuits underground for about one year. One style of cable by a prominent manufacturer was alone used. The wire was drawn into a composition conduit, which had manholes at the corners.

Quite an amount of trouble was caused in the start off, by difficulty caused by abrasion to cable in drawing the wire into the conduit. The experiments were continued for one year. They caused a great deal of trouble within the lighting contracts, and at the end of that time were abandoned. He considers the chief troubles to be defective conduits, water in the conduits, and deterioration of the cable, also trouble in defective insulation, defects in the joints, and trouble in making connections through iron pipes from the conduit to the surface.

He does not consider it practicable to place his wires underground, and states: "I don't know of any system that has yet proved satisfactory;" and further states: "I know of no system to-day which, even at any expense, has proved satisfactory, except a system of subways built large enough for men to walk through their entire length."

In answer to the difficulties of placing wires underground, he states that he considers the difficulties to be commercial, electrical, and mechanical perfection, and still not be so expensive (in the end) as to make the commercial objection insurmountable. He did not have exclusive control of the conduit.

The ordinance passed by the Common Council in his city in 1886 stated 'that their committee had examined the subject, and found the putting of all electrical wires underground feasible, and ordered all wires within a few months, and those outside of this district, underground within one year." He has been brought before the court a number of times on complaint of the city attorney, but nothing yet has been done in the matter.

Fourth: The writer has made two experiments during the last summer, one of which was a failure and the other a partial success, though the duration of the second test and the position it occupied in the circuit was such as to give little importance to the result. The wires were pulled into a wooden conduit, there being two ducts in each conduit. Cables did not work satisfactorily. He states that the failure is due entirely to defective insulation. In answer to the question if he considers it practicable to place his conductors underground, he replies, "We do not with any system known at present." In answer to the last question, concerning the difficulties and objections to placing wires underground, he states: "The difficulty is particularly commercial, though I have seen no system which I think will properly insulate the conductors."

Fifth: The writer has placed two circuits underground about the first of the present year. The cables used are those manufactured by six of the most prominent companies. They have been drawn into an asphalte conduit, 12 ducts in each conduit. The duration of his experiment has only been about a month and a-half, and he states that it is too early to tell what will be considered the result of the experiment. In answer to the question if it would be considered practicable to place the wires underground, he states, "Have seen nothing yet that will answer." In answer to the question as to his opinion regarding difficulties and objections to going underground, he replies, "Chiefly commercial, partly electrical, and partly mechanical." He has exclusive control over his own style of conduit.

Sixth: The writer has had wires in the conduits for about five years. The mains were carried through the streets in a composite system of conduits, the connections are made from the system to the cellars through iron pipes, and the wires are conveyed then through cellars, connection being made from the cellars to the houses. The cellars run completely around the block, and permit of free access to them for the purpose of repairing or making connections to wires.

He has used three different kinds of wires in the conduits, the cables now in use having been in position for about thirteen months; although he has had trouble with them, he claims that satisfactory service can be maintained in his particular locality, as he considers the question of the distribution of power and light an exceedingly simple one in his city, which is probably the only city which is so fortunately situated.

He has in all about thirty-two circuits. He states that he is on the right track regarding the placing of wires underground, and that the system such as he operates will run satisfactorily. The cables that he is using are guaranteed for three years. The trouble that he had with his first wires was mainly due, as far as he can ascertain, to the fact that the insulation surrounding the wires was not of sufficient thickness, and the main conduits themselves were not dry. He controls his own conduits exclusively.

Seventh: The writer has made some practical experiments and tests with cables under water; these were manufactured by two of the most prominent companies. The cables did not, however, work satisfactorily, lasting, as they did, from three months to one and a-half years. He lays the cause of failure to the effect of water upon the cable, and the deterioration in the insulation of the wire. His opinion, based upon the tests he has made, is that he does not consider it practicable to place his conductors underground; considers that the difficulties are both electrical, mechanical and commercial; had exclusive control over such conduits as he used.

In summarising the results of the experiments in these cities, in one case only did the electric light company place its wires underground willingly; in all others they were forced to do so by the local authorities.

In only one instance have the experiments or practical workings proved satisfactory; the only other case that they did not report adversely being where the wires had only been in operation about forty days. The average voltage that we used on all the circuits tested was 1,893 volts; the current was ten amperes; the average thickness of insulation over wires was 9·32 of an inch; and the average length of cables tested in each case was about 4,600ft.

In considering the second class of answers, namely, those who have not yet made any extended practical test, their answers have been directed mainly to the last four questions, the first two of which relate to action by the municipal authorities, and the last two consider the practicability and the difficulties of placing wires underground. In very few of these cities have the municipal authorities yet taken any steps toward action upon the matter, having been delayed in awaiting the solution of the underground question in other cities.

In answer to the question, asking them if they considered it practical to place their conductors underground, 104 have replied that their opinions, based upon tests that they have seen and such information as they have been able to obtain, both in this country and abroad, is "that it has not been practical to place the wires conveying high tension electric arc light currents underground."

Two have answered that they considered it practical to do so, but state that at the present time they have no wires underground.

In answer to the question, which asks their opinion regarding the greatest difficulties to be met with in considering the placing and operating of underground wires, they all unite in the opinion that the difficulties are mechanical, electrical, and commercial.

They consider that the question of obtaining a satisfactory conduit has not been properly solved, and that even if that should be solved in the future we cannot even at this time obtain a satisfactory insulation for the wires that will not deteriorate within a few years, and become perfectly useless as an insulator when subjected to the action of steam, water, and gas. The great difficulty of making connections for buildings and lamps, and the absence of any satisfactory system of subsidiary conduits, is considered by all as a bar to successful operation, as the difficulty of drawing in cables without abrasion to the insulating covering, even with the most careful handling, is very great.

The commercial objection is considered a very great one, as not only is the first cost about eight times heavier than that of an overhead system, but the repairs to the cables due to the deterioration of the insulation and other defects caused by mechanical or electrical deficiencies would be very much heavier than the expense of operating and maintaining overhead systems, and that the prices at which they are now furnishing the electric light would have to be very materially increased to meet these extra and very heavy expenses. A system of tunnels through all the principal streets is considered to afford the only means for the solution of this problem.

The committee also sent a letter asking many of the questions that were sent in the circular to all of the electric underground wire companies, and in response received quite a number of communications from the cable companies. Most of them said that at the present time they were unable to give any information in regard to underground wiring, as they have had very little experience with wires for that purpose, but that they do not doubt that in the future the state of the art will permit of the wires being placed underground. Other companies reply that the wiring of their system that has been used for underground purposes has been for potentials under 2,000 volts, and that they have met with entire success with potentials of a system with 1,000 volts. And they do not anticipate in the future that they will have any trouble in furnishing wire to meet the requirements of the electric lighting companies, but at the present time they have not yet done so. They unite in stating that they think that the question of insulation of high voltage of currents should be solved by the using of good, durable, thick insulation. Their experience in conduits has been, that they do not want creosoted wood, but would prefer to have their wires buried in the ground, or under water, and would recommend at the present time that single conductors should be used. They seem to be about evenly divided on the question as to whether lead-covered cables should be used for underground purposes."

LEGAL INTELLIGENCE.

King, Brown and Co. v. The Anglo-American Brush Electric Light Corporation (Limited).

In continuation of the evidence of Mr. C. F. Brush, taken on commission in Cleveland, the witness's cross-examination proceeded as follows:—

Parts of the first edition of the Haddan patent referred, broadly speaking, to a shunt dynamo. The passages in the specification of 1878 referring to that were retained in the specification as amended, and disclaimed excepting claim 8, which was disclaimed and cancelled. *Q.* Do you in the passages so retained represent a shunt dynamo as part of your invention?—*A.* Most assuredly not as part of my invention intended to be covered and claimed by the present Haddan patent. Had I designed or intended the "simple-shunt" form of dynamo to constitute an embodiment to be com-

Digitized by Google

prehended by the Haddan patent the eighth claim would not have been cancelled. I consider, and still consider, that the cancellation of claim 8 removed from the Haddan patent all pretext that the "simple-shunt" form of dynamo is intended to be, or is in fact, embodied within the scope of invention designed to be covered by that patent as it now stands. Whatever references to a simple-shunt dynamo that now appear in the Haddan specification remained simply as gratuitous suggestions or descriptions of that which the patent does not claim or cover, and which serve to more clearly and definitely indicate by contradistinction just what the patent in its present shape is intended to include and cover, namely, a compound-wound dynamo, so far as division 4 of that patent is concerned. *Q.* Was it known in 1878 that the system of compound-winding, or what is the subject of claim 7 in the letters patent of 1878 as finally amended and disclaimed, was applicable or useful in connection with electric lighting? When did this first become known so far as you are aware?—*A.* In 1878 the art of incandescent electric lighting was still in its formative stage, and had not reached the practical development which it soon after obtained. My invention of the compound-wound dynamo played no unimportant part in the practical solution of the problem of incandescent lighting. So far as concerned are electric lighting, I very well understood in 1878 the non-suitableness of the compound-wound dynamo for operating arc lamps. But upon the production of my compound-wound dynamo its application to incandescent lighting was apparent, and was recognised soon after. *Q.* Did you tell Mr. Swinburne, in May, 1882, in Cleveland, Ohio, that you did not think a constant-potential machine could be made, but that if he would take the responsibility of ordering the machines you would make them, or anything to that effect?—*A.* I do not remember ever making such, or substantially such, statements to Mr. Swinburne, and do not believe that I ever did. I may, however, have discouraged, and probably did discourage, the construction of the special machines he wanted, knowing that the commercial demand for them at that time had not become sufficiently large to warrant the time and expense that would be necessary to determine the relative proportions and details of construction. *Q.* Did you ever say to Mr. Swinburne, in May, 1882, that you had discouraged the construction of these machines, knowing that such construction would require considerable time in calculation, superintendence, and testing on your part, without leading to the construction of such machines at that time for commercial purposes.—*A.* I have no remembrance of any such conversation, either in substance or effect, and do not believe that it ever occurred. In 1882 I had the invention of the compound-wound shunt dynamo and its essential principles of construction and operation as clearly and distinctly in my mind as I have to-day, and could not have any reason for speaking in effect as the question implies. I had completed the invention of the compound-wound dynamo several years previously, and had filed my application for my United States letters patent there on March 11, 1878, wherein I had fully illustrated and described the compound-wound dynamo. Upon this application my American patent of July 22, 1879, was granted. I was fully prepared in the early part of 1878 to construct a compound-wound shunt machine, and could have made one then without any extraordinary consumption of time in calculation, superintendence, or testing on my part, and with a certainty of making a commercially acceptable machine. As a matter of fact, before the early part of 1878 my licensees in America were making and selling my compound-wound dynamo for electro-plating purposes, and a number of them were then already in very successful commercial use. Referred to a sentence in Haddan's specification, witness said that using the terms "pure shunt" and "simple shunt" synonymously he found that both a simple-shunt and compound-shunt machine were referred to there. A workman with Haddan's specification might hit constant or approximately constant potential in his first construction of field coils, or being experienced in the construction of series machines of the same type he might be able to calculate or gauge the proper proportions, as he did himself. He could not fail by following the specification and drawing to make an approximately constant potential machine, and a machine much better adapted for the purposes requiring constant potential than a series machine. Asked if simple-shunt machines were used for electro-plating prior to Haddan's patent of 1878, he answered that, judging from the statement made in the specification of the Clark patent of 1875, he should say that a simple-shunt machine had been attempted to be used, or, at least, suggested, for "electro-metallurgical" purposes, which evidently referred to electro-plating. *Q.* Had you or anyone else any knowledge of incandescent lighting at the date of Haddan's patent?—*A.* Strictly speaking, yes. Incandescent lighting, however, had not reached its practical or commercial development and introduction in 1878. In answer to other interrogatories, he said that it was of great importance that the polarity in machines used for electro-plating should under no circumstances be liable to change. In arc electric lighting it was important that the dynamo should not change its polarity. In incandescent electric lighting, however, the lamps would burn as well with the dynamo current flowing in one as the other direction. But for incandescent lighting there were other essential requirements that necessitated the employment of a dynamo whose construction is of such a character that under ordinary and normal conditions its polarity is not at all liable to reversal for whatever purpose it might be used, whether for operating lamps or otherwise. The compound-wound machine was not more liable to change polarity when used for electro-plating than the plain shunt machine. *Q.* Is Varley's description of how he prefers to employ a part of the electricity to maintain the magnetism of the soft-iron magnets not a description of series-shunt winding?—*A.* I cannot so understand it. Varley distinctly states: "Part of the electricity developed by the machine is diverted to maintain the magnetism of the soft-iron magnets, and the remaining portion is used to produce the electric light." In a compound-wound dynamo all of the electricity developed by the machine, and not part of it only, energises the field-magnets. *Q.* Is it possible to make a compound-wound machine so as to give an approximate constant potential, while at the same time doing work in the shunt circuit external to the machine?—*A.* Not if the external working in the shunt-circuit is variable in amount, or involves a variation of resistance in the external part of the shunt circuit, or involves the opening of the shunt-circuit at intervals, however brief such openings may be. *Q.* With regard to compound winding, state what are the differences between the system disclosed in Haddan's patent and that disclosed in Varley's patent?—*A.* I have already repeatedly stated that I cannot possibly understand that Varley disclosed or described or suggested compound winding as viewed in the light of the state of the art at the date of his specification. I still maintain this opinion, and therefore cannot discuss the differences between Varley's construction and the compound winding disclosed in the Haddan patent, as this pre-supposes or assumes that Varley showed compound winding, which he does not. Replying to further questions the witness said that the two elements in Haddan's seventh claim were a shunt coil and a series coil. Such a shunt coil was not to his knowledge known before the date of Haddan's patent; and such a series coil was not, strictly speaking, known prior to that date. In 1878 the purpose of a shunt coil was not the same as that of a series coil. The same result could not be obtained in both cases. *Q.* In the subject matter of the seventh claim is there simply the addition of two methods of producing the same result, both of which were known or in use prior to the date of Haddan's patent?—*A.* Nothing of the kind. The subject matter of the seventh claim is a combination of elements and instrumentalities in a dynamo that, so far as I am aware, produced a radically new type among electrical generators. That claim refers to and covers a unitary device, and not two old methods in any sense; and this unitary device is a dynamo having distinctively peculiar and highly important and valuable functions and adaptabilities, neither attained nor approximated by any prior invention that has ever come to my knowledge. This machine satisfied wants that were widely felt long prior to the date of the Haddan patent—electro-plating for instance, and it went into wide and successful use promptly after its invention. It appears to me that this fact alone goes far towards convincing of the fact that whatever older methods might have been known or adopted their failure to receive the approval and acceptance that was immediately given the dynamo referred to in the seventh claim indicates conclusively that they were not only deficient or inoperative, but that they did not contain or approach the invention covered by the seventh claim. *Q.* What is the invention claimed in the seventh claim?—*A.* In a dynamo electric machine the wire helix E having a comparatively high resistance and kept in close circuit while the machine is running in combination with the magnetic wire or helix F as commonly employed, substantially as shown in Division 4 of the Haddan patent. *Q.* State what is disclosed in Haddan's specification as to compound-winding which was not previously disclosed in Varley's specification?—*A.* Everything. The Haddan patent definitely and completely discloses compound winding, whereas there was nothing in the Varley patent that disclosed it; but, on the contrary, all the interpretations that can be gathered, however dimly, from its vague, incomplete, and uncertain statements, and its drawings, taken as a whole, are entirely repugnant to the conclusion that Varley had ever conceived the idea of the compound-wound dynamo, and much less that he disclosed such an invention in his patent. If Mr. Varley in his patent had intended to disclose any idea of a compound-wound dynamo, or to increase any form or construction of such an invention, it is impossible for me to explain or to understand why he did not make such a fact at least remotely apparent in the specification and drawings on the claims of his patent. The drawings do not illustrate or suggest compound winding. The specification did not disclose it, and the claims do not in the remotest degree refer to such an invention, or to anything that would require a compound-wound dynamo, or suggest its desirability. In reply to the question—Was the only object of the seventh claim, as at 1878, to improve the application of electricity to electro-plating? he said that he had stated in the specification that "other useful applications of a permanent field machine will readily suggest themselves," and that he had had also telegraphy in mind. He had no doubt that Varley, when he said that "part of the electricity developed by the machine is diverted to maintain the magnetism of the soft-iron magnets," and again, that "in order to ascertain the amount of electric force which is being produced, &c.," meant identically the same thing in using the terms "electricity" and "electric force." *Q.* If in Varley "electricity" is held as equivalent to "electric energy," does Varley correctly describe compound winding?—*A.* Not correctly. The passage referred to would then read in substance, "Part of the electric energy developed by the machine is diverted to maintain the magnetism of the soft-iron magnets, and the remaining portion is used to produce the electric light." This would not correctly describe compound winding, because in compound winding not only is a part of the "electric energy" diverted to energise the field-magnet, but also a part of the remaining portion of the electric energy is used or absorbed for the same purpose, and to this extent, which is considerable, cannot be used to produce the electric light. I will add that I cannot accept as justified by Varley's specification the definition of the word "electricity" as being "electric energy," as the question provides. *Q.* Would a Varley machine, wound with series and shunt magnet coils acting together, be an infringement of Haddan's specification if made now?—*A.* I would be glad to answer this question definitely if I could determine to my satisfaction what sort of a machine a Varley dynamo is or was. If Varley should wind, connect, and use his machine in the manner customary with compound-wound machines, as such machines are at present made and used, I should say that such a construction would infringe the Haddan patent. But Varley does not appear to have done or indicated this.

Lord Trayner has fixed the hearing of counsel on the evidence for the 22nd May.

THE CENTRAL LIGHTING STATIONS OF FRANCE.

This list of French central stations has been, in part, compiled from a Paper read before the Société Industrielle du Nord de la France by M. Aimé Witz, but has been enlarged and revised by our Paris correspondent.

Town.	System.	Output in horse-power.	Distribution.	Remarks.
Bellegarde	Edison (Low tension).....	80	Overhead	Water power
Tours	Gaulard-Gibbs transformers	300	Partly overhead and partly underground	
Roche-sur-Yon..	Thury (Low tension)	45	Overhead	Water power
St. Etienne.....	Edison (Low tension).....	190	Overhead	
Bourganeuf.....	Thury (Low tension).....	30	Overhead	
Dijon	Edison (Low tension).....	35	Overhead	
Coatigrach (Finistère) ...	High tension...	45	Overhead	Water power, accumulators employed after midnight
Compiègne	Low tension...	130	Overhead	
Nancy	Ferranti transformers	625	Concentric cables underground.	
Cité Bergère (Paris)	Edison (Low tension).....	800	Underground	
Palais-Royal (Paris)	Edison (Low tension).....	600	Underground	
Faubourg St. Martin (Paris)	Gramme (Low tension).....	125	Overhead	
Lyon	Société Alsacienne de Constructions Mécaniques (Low tension)	600	Underground	
Perpignan	Thury (Low tension).....	100	Overhead	
Bordeaux	Gramme (Low tension).....	50	Underground	
Rouen	Edison (Low tension).....	100	Overhead	
Le Havre.....	Edison (Low tension).....	—	—	In progress.
Toulon.....	Société Alsacienne (Low tension).....	1'0	Underground	
Montpellier.....	Société Alsacienne (Low tension).....	300	Underground	
Manosque	Thury (Low tension).....	50	Overhead	Water power

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

[Our usual American correspondence has failed to come to hand this week, but the following paragraphs were crowded out of our last issue.]

The annual meeting of the stockholders of the Westinghouse Electric Company was held at Pittsburg on the 12th ult. The business during the past year has been prosperous, and the earnings up to December 31 were more than sufficient to pay the usual quarterly dividend of 1½ per cent. During the past year the company has acquired by lease the control of the Consolidated Electric Light Company and the Sawyer-Man Electric Light Company, and the company now owns $1,235,000 par value of the capital stock of the Consolidated Company, the capital of which is $2,500,000. The earnings from these two companies for the first quarter have been sufficient to pay the rental. In November, 1888, the company acquired the capital stock ($135,000) and outfit of the Waterhouse Electric and Manufacturing Company, together with valuable inventions. In January an agreement was entered into, as you have already noted, with the principal owners of the United States Electric Lighting Company, whereby this company purchased seven-fifteenths of the stock of that company (capital, $1,500,000), and whereby that company was leased to the Westinghouse Company. By the acquirement of the control of the Consolidated and United States Companies, the Westinghouse Company "has secured a favourable position with reference to patents, having now the exclusive rights under the Sawyer-Man patents and numerous other valuable inventions." The orders received for central station apparatus since the 1st January aggregate a capacity of 50,000 16 candle-power lights. The number of lamps sold by the Sawyer-Man Company in January was 92,000, while the United States Company for the same period sold 50,000 lamps. The three lamp factories are now capable, with the present machinery, of producing at least 81,000 lamps per day.

Some time ago I alluded in this letter to the remarkable growth of the electric railway business of the Sprague Company, and the electrical papers this week give illustrations of three more lines lately completed by that company, those at Brockton, Reading and Wilmington. The Brockton road is four miles long, and operates four cars. One of the preliminary tests through which the road passed most successfully, was made by bunching all the cars at a point on the road farthest distant from the power house, and starting them all up at once. Although the power for all the cars was transmitted between two or three miles, the cars started off promptly, moving rapidly, and showing that the entire power can be easily transmitted and applied even at the farthest end of a line, and that the load upon the dynamos can be varied from zero to a maximum without any detrimental result to the electrical apparatus. The Reading road has a single track, and is about two miles long. It has been in operation two months, and is giving great satisfaction both to its directors and to the public. The Wilmington line has been working for eight months, and the best proof of its success is the fact that the directors have ordered an additional number of cars. The president of the company pronounces the system a complete success, and is of opinion that it is not only the most economical mode of running street cars in suburban districts, but that it is markedly cheaper and more efficient than horse-power. It has secured the favour of the public by its smooth and rapid motion, and has received commendation on all sides. The Sprague Company has just made another important installation on the electric branch of the West End Road at Boston, and at an inspection of the line on February 5 most of the prominent street railway men of New England were gathered. The power plant consists of two Armington and Sims high-speed engines of 200 horse-power each and four dynamos of 80,000 watts capacity each.

In the meantime New York has been threatened with a revival of schemes for grid-ironing the city with a system of cable roads, and it seems likely that if anything can result from the influence brought to bear upon the Legislature at Albany the project may be put through. But it appears to meet with pretty strong objections from Mayor Grant of this city, who says that "the Bill in question now before the Assembly is inimical to the best interests of the community and assails public rights." Hence, it is not likely to find much favour with the public, which will, I think, soon wake up like their neighbours in Boston to the benefits to be derived from the adoption of electric power on the city roads. Although several notable demonstrations of the ability of the electric motor to do the work have been given in this city, New York is still very much behind, and ought to be setting a better example.

PARIS NOTES.

(FROM OUR CORRESPONDENT.)

March 13th, 1889.

The fall in the shares of the Société des Métaux, which I spoke of in my last letter, has since greatly increased, and the shares have at the present moment no marketable value at all. The copper monopoly may be considered as dead, much to the benefit of consumers of this metal in general, and of electricians in particular.

The Conseil Municipal has introduced a modification in the Cahier des Charges concerning electrical central stations. This modification relates to Art. 27, which has been modified as follows: "All the material, as well as lamps and wires, must be furnished

Digitized by Google

by French firms, and manufactured in France." This decision, which cannot be disapproved of by any Frenchman, may give a check to the ardour of some of the *concessionaires*, who have, it is said, already treated with English and American electrical firms for the supply of their material. Up to this date only four of the *concessionaires* out of the six have deposited the required caution money of 300,000fr. Those which have done so are the Edison Company, the Marcel Deprez Company, the Société du Secteur de la Place Clichy, and the Popp Company. Up to now nothing certain can be said as to the systems these companies will adopt, but the systems employed by them will be probably as follows :—Ferranti transformers by the Marcel Deprez Company, accumulators by the Popp Company, partly Zipernowsky transformers and partly low tension by the Edison Company ; low tension by the Secteur de la Place Clichy. Nothing has been settled yet concerning the lighting of the Boulevards during the forthcoming Exhibition, though some decision will be arrived at by the Conseil Municipal in the course of next week.

In the provinces, Marseilles, Nîmes, Rouen, Avignon, &c., have their municipal bodies occupied with the question of the electric light, and if France felt some apprehension in accepting the new light when it first appeared, it will certainly not be long before it is at the head of this improvement in the private and public lighting. The last meeting of the Société Internationale des Electriciens was partly occupied by a lecture by M. Cance "On the Electric Lighting of the Magasins du Bon Marché." The total motive power amounts to 1,699 horse-power, with 799,000 watts available, if necessary. The ordinary lighting consists of 276 Cance arc lights, 84 Jablochkoff candles, and 3,000 16 candle-power incandescent lamps.

The illuminated fountains which formed so notable a feature of the Exhibitions at London, Manchester, Glasgow, and Barcelona will not be missing at the one in Paris. We do not intend to rest content with what has already been done, but hope to surpass all the beautiful effects hitherto shown. When the illuminated column of water displays its variegated colours in the evening all the surrounding fountains and water will be simultaneously lit up, and it is expected that effects unlike any yet seen will be obtained.

Some of your readers may perhaps like to know that full information with regard to the electricity meter competition can be obtained on application to the Secretaire Général de la Préfecture de la Seine, Paris.

A French Company, calling itself the Société Electro-Métallurgique, has just commenced the manufacture of aluminium alloys by the Heroult process. The works are at Froges (Isère), and are equal to a daily output of 3,000 kilogrammes of alloy. The current is produced by two dynamos, each giving 7,000 amperes and 20 volts. These dynamos are separately excited by a machine giving 350 amperes and 65 volts. The motive power is obtained from two vertical turbines of 300 horse-power each.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *March 13th*, 1889.

The Statistical Department of the Ministry of Commerce have published some interesting figures regarding the development of the Post and Telegraph Service in Austria during 1887, amongst which I note that the total length of the telegraph lines in Austria in 1887 was 3,847 kilometres, and 7,215,172 telegrams were transmitted, against 6,909,638 in 1886, an increase, that is to say, of 4 per cent.

Messrs. Siemens and Halske are actively pushing the completion of their Central Station in the Neubadgasse. They are also laying new cables, one from their Central Station through the Nagler and Irisgassy, to the Freiung, another from the corner of the Herrengasse and Kohlmarkt, through the Schaüflergasse, Ballhaüsplatz, Volksgarten, Burgring, Bellariastrasse, to the new Volks Theatre, which they are going to light up. Messrs. Egger and Co. have sold their glow lamp factory in Budapest to a company. The factory is to be refitted and to be made capable of an output of 6,000 lamps daily. The electric light installation in the Houses of Parliament is completed and works well. The new installation in the Rathhaus is progressing rapidly. I hear also that the Wiener Elektricitäts Gesellschaft have obtained a concession from the municipality of this city for the erection of a central station in the Kopernikus-Gasse.

The Electrotechnical Society of Vienna has just nominated a committee to draw up a set of fire rules for electric light installations ; the chairman of the committee is M. Ross, of the firm of Ganz and Co. Karlsbad, following the example of Marienbad, is to have a central lighting station. The plant will comprise two 50 kilo-watt machines, supplying 35 12-ampere arcs and 100 incandescents for street lighting, and over 2,500 incandescents for the hotels. Bilin (Bohemia) will shortly have its streets lighted by arc lamps. The electric railway scheme between Baden and Volsan it is expected will be sanctioned before long by the authorities.

NOTES FROM BRUSSELS.

(FROM OUR CORRESPONDENT.)

BRUSSELS, *March 11th*, 1889.

At its last sitting the Electric Lighting Committee nominated by the Administration Communale decided that the electric lighting of the town should not be undertaken by the municipal authorities. The first central station is to be worked by a company under a license from the town, which is to have the option of purchasing the undertaking at any time. Tenders will be received up to the 1st July next, and the bases upon which they must be drawn up are as follows :—Any system of distribution whatsoever may be employed, but it should be applicable to any purpose to which electricity may be put, and in any case it should permit the use of electric energy for motive power as well as for lighting. The station must be of such a size as to allow of double the original plant being installed. Amongst other information the tenders must explain how the contractors propose to maintain a constant potential, and must specify the nature of the insulation of the cables, the method of laying the mains underground, and of running the wires into the consumers' houses. The contractors must also give detailed information as to prices and method of charging. If a low-tension system of distribution is employed the tender must be drawn up on the supposition that the central station is situated at the north end of the Halles, with a second station serving the upper part of the town behind the Eden Theatre. If high-tension currents are employed, some ground near the gas works may be supposed to be the site of the central station. The staff of the undertaker will be paid by the town, and the undertaker must superintend the station in person, or he must delegate competent electricians to take his place. Finally, the accounts of the contractor, and everything relating to the working of the station, is to be under the control of the town.

The authorities have, it will be seen, taken every precaution to ensure for themselves a preponderating influence in this matter, so that should the experiment turn out a success, and affect the gas revenue, the municipality may be in a position to reap the advantage, and recoup itself for the diminution of income from the gas works.

The Houillères-Urries at Gilly have just put up a large electric light installation on the Dulait system. The lights are all above-ground, and comprise five 2,400 candle-power arcs, eight 1,600 candle-power arcs, and about 100 16 candle-power incandescents. The current is supplied by a Dulait dynamo, giving 350 amperes at 110 volts, and running at only 350 revolutions per minute.

CORRESPONDENCE.

THE DAVEY-PAXMAN ENGINE TRIALS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : In your article on the Society of Arts trials of motors for electric lighting you remark, in regard to the engine trials, that the results arrived at with this engine confirm in a remarkable degree those obtained by a similar engine by the same firm at Newcastle. As this is a matter of scientific interest, allow me to point out that you have been misinformed.

By reference to the data given below, taken from the Society of Arts *Journal*, February 15, 1889, page 235, and from *Engineering*, November 18, 1887, page 518, it will be seen that the Newcastle supposed results differ from the recent experiments not by 1 or 2 per cent., but by more than 10 per cent.

The recent careful trials of the compound non-condensing engine may be taken as not only correct but as showing almost the best results attainable with that form of engine of that size and design and under the conditions of trial. As such they are of great practical value.

There is a marked advantage with 190lb. as compared with 120lb. boiler pressure.

It is reasonable to suppose that the engine of 1889 had some structural advantages over that of 1887, and it certainly had the advantage of higher boiler pressure. It is, therefore, reasonable to suppose that the engine of 1887 must have used slightly more water and coal than that of 1889.

In the table below the water per brake and indicated horse-power for 1887 are calculated from data given in other parts of the R.A.S. tables :—

	1887.	1889. (mean.)
Water per indicated horse-power	18·7 ...	20·51
Water per brake indicated horse-power	21·0 ...	23·3
Coal per brake horse-power	1·85 ...	2·04

Digitized by Google

Both these sets of figures cannot be right: those for 1887 are from 11 per cent. to 12 per cent. better than those for 1889.

For my part, having had the honour to know personally Prof. Kennedy, Prof. Barr, and Mr. Halpin; having used the Appold brake for many years, and also having made many experiments with compound non-condensing engines, I accept the recent experiments as correct, and reject those of 1887 as impossible under the conditions and erroneous to at least the degree above named.—Yours, &c., WILSON HARTNELL.

[Mr. Hartnell's letter calls attention to a question of some interest, but the importance of the figures he mentions in correction of the remarks we made depends on the view taken as to the similiarity necessary in two sets of figures to permit the one to be considered confirmatory of the other. The Paxman engine in the Society of Arts trials at South Kensington used 2·01lbs. of coal per brake horse-power. At Newcastle a similar engine used 1·874lbs. The approach to similiarity in these figures would not of course, if taken alone, be considered as confirmatory of the same degree of accuracy in the methods of obtaining them, but we must point out that the coal used at South Kensington contained but 84·5 per cent. of carbon, as against 88·4 per cent. in that used at Newcastle, representing a difference of 551 thermal units per lb. of coal. The hydrogen seems to have been the same in both coals, but nitrogen and ash were both greater at South Kensington. The 2·01lbs. of coal used in the Society of Arts trials thus gave off at least 1,101 units less than the coal used at Newcastle. Of the difference of 10 per cent. between the 1·874lbs. of coal used at Newcastle and the 2·01 used at Kensington, then, the difference in the quality of the coal thus explains nearly one-half. Another important difference is the fact that while the steam jacket was used at Newcastle, it was not used at Kensington. We have always believed that engineers were agreed as to the value of a steam jacket, and that a gain by its use of 5 per cent. is a modest view of its value. Taking these facts into consideration, we are still of opinion that there is a striking similiarity between the performance of the engine at Newcastle and that at Kensington. We do not attach much importance or any to the discrepancy between the quantity of feed water used at Kensington and that used at Newcastle, because the jackets in the latter engine drained back into the boiler, so that it would be difficult to say what quantity of water was evaporated.

The steam pressure used at Newcastle was 150lbs. per square inch, not 120lbs., as mentioned by Mr. Hartnell. We were not aware that Prof. Barr and Mr. Halpin were concerned in the trials at South Kensington, but we quite agree with Mr. Hartnell that the 1888 (not 1889) trials yielded figures which will not give rise to the complaint which was made concerning the comparative tests at Newcastle.—ED. *E.*]

ON THE DESIGNING OF CONTINUOUS-CURRENT DYNAMO MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On page 487 of *The Electrician* Prof. Jamieson, in speaking of the magnetic resistance of the armature core, gives the following formula:—

$$R_a = \frac{L_a}{S_a}.$$

Where R_a = magnetic resistance of armature core, L_a = mean average length of armature core magnetic circuit in inches: if there was only but one path instead of two, we should have to multiply by the coefficient 2, as in equation (IV.), but

$$\frac{2\,L_a}{2} = L_a.$$

S_a = cross sectional area of armature core in square inches = twice radial depth × length of armature core.

Should this formula not be

$$R_a = \frac{2\,L_a}{S_a}.$$

Then further on, on page 489, in applying this formula to an example of a given dynamo of gramme type ring armature he says:—

$$R_a = \frac{15}{25} = \cdot 6,$$

where radial depth of core = 1·75 inches, diameter of core = 10 inches, length of core = 9 inches, L_a = 15 inches, S_a = 1·75 × 9 less 20 per cent. for insulation and air spaces = 25 square inches.

Should not $$R_a = \frac{2 \times 15}{25} = 1 \cdot 2.$$

Of course this is assuming that the magnetic resistance remains constant for any degree of saturation of the core, which is not the case; also, that the Kapp co-efficient 2 is sufficiently near the mark for soft wrought iron, which is doubtful, as there must be considerable variation in this co-efficient depending upon the nature of the iron used.—Yours, &c.,

Edinburgh, March 11, 1889. WM. GEIPEL.

INTERCALATING APPARATUS FOR PORTABLE INCANDESCENT LAMPS.

In the annexed engravings we illustrate an improved switch or "intercalating apparatus" brought out by Messrs. Mix and Genest, of Berlin. The apparatus hitherto in use has the disadvantage that the switches must either be turned (screws or bayonets), or they cannot be turned at all, because the contact pieces are not centrally arranged. The idea of arranging the two contact pieces of the switch in the form of concentric tubes in and around the switch contributes to give the apparatus a solid construction. The contact pieces are connected by soldered copper wire with the

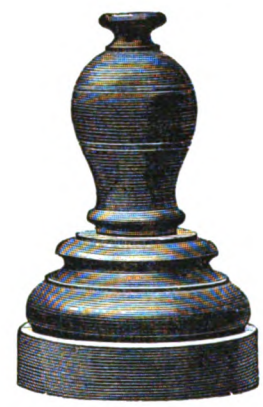

FIG. 1.

segment-like binding screw in the handle. Fig. 1 shows the apparatus complete, while Fig. 2 shows the construction. The contact

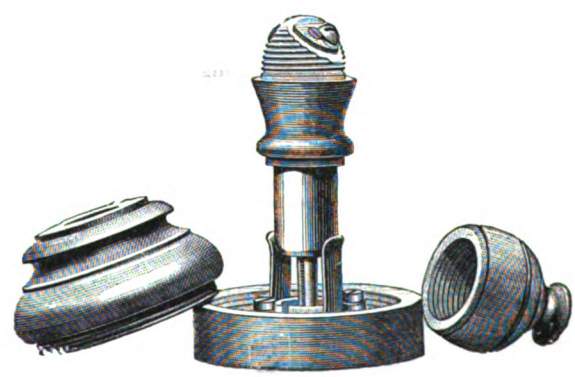

FIG 2.

pieces of the connecting box are suitably arranged, and the two spring-plates and the joint are stamped out of one piece and fastened by one binding screw. The spring pin being split with a conical top, when pressed into the interior contact tube completes the electric circuit with the ground plate fixed by the second binding screw. Besides its suitable and solid form, this apparatus has the advantage that the intercalation of portable glow lamps can be easily effected in the dark. No turning being necessary, the possibility of injuring the wire at the joining points is very remote. The apparatus can either be fixed on the wall or on a gas tube hanging from the ceiling.

COMPANIES' MEETINGS & REPORTS.

The Anglo-American Brush Electric Light Corporation (Limited).

The eighth ordinary general meeting of this Corporation was held at the Cannon-street Hotel on Wednesday, under the presidency of the Right Hon. Lord Thurlow, F.R.S.

The SECRETARY and MANAGER (Mr. Emile Garcke) read the minutes of the last meeting, which were confirmed and signed as correctly entered. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: I will now proceed, gentlemen, without further loss of time, to say a few words, as is customary on these occasions, explanatory of the terms of the report and of the figures which are contained in the balance-sheet. I think, however, on the present occasion that the report is so full and exhaustive, and the figures so satisfactory, that it will not be necessary for me to detain you very long at this stage, at any rate, of our proceedings. At a later stage we shall be happy to give you full explanations on any point that you may very naturally raise and desire further information upon. But I am bound to say that I think, contrasting this report and balance-sheet with those of the previous four or five years, it will be difficult for any of the shareholders to entertain other than a feeling of satisfaction and great hopefulness for the future. This has been undoubtedly a year of progress, and very marked progress, in all electrical affairs. To what extent the improvement is due to the Act of Parliament that was passed last session you must each of you judge for yourself. My own impression is that the advance in electrical science, and in its application to domestic affairs in almost every shape and form, is due to a very large extent to the passing of that Act of last year, amending Mr. Chamberlain's well-known Act of 1882; and I am glad to be able to say that I believe that Mr. Chamberlain himself heartily approves of the action of Parliament last year, and recognises the advantages that have ensued from it. Well, gentlemen, that being so, I think I need not detain you at much greater length on that point, but it may be interesting to you to know that at the present moment there are no less than twenty-one central stations established, or in course of progress, in the metropolis alone. You all know that in every considerable town in England the same thing is taking place, and not only in every considerable town, but in many second and third class towns throughout the country. Well, in a very large number of these enterprises we are interested not only as manufacturers but in other ways. Under our Articles we are, as you know, entitled to participate in this kind of undertaking, and although we proceed with the greatest possible caution we deem that it is advisable, seeing that their interests are identical to our own, to embark occasionally in and assist these various local enterprises. There is one, for example, that I desire to mention in which we are embarked, and in which we take the very greatest interest. Some of your Directors are Directors of the company, and I am thankful to say that it is making very rapid and satisfactory progress. I allude to the Chelsea Electricity Supply Company. We have got a large area to supply, and we have made most favourable contracts not only with the consumers but with those who are manufacturing jointly with ourselves the plant that is supplied, and I venture to say that the Chelsea Company will be a model in every way to those which are hereafter established. We have proceeded with the very greatest care in the consideration of the details requisite for the undertaking. Of course central lighting installations and central lighting stations are still to a certain extent matters of novelty. A certain amount of experience has undoubtedly been gained, but a great deal also undoubtedly remains to be done in the way of ultimately ascertaining what is the best form of building, the best type of machinery, engines and various other matters. All of these matters have received the most careful attention that we have been able to give to them. Anything that the Chelsea Electricity Supply Company has done will be a model of what such a station ought to be, and will no doubt give general satisfaction over the large area which it will very shortly light. At Bournemouth we are proceeding on a different system. At Chelsea the system that we have adopted is to use underground mains and accumulator stations. At Bournemouth we use alternating currents and overhead mains, which, in a comparatively rural district like Bournemouth, the light being used economically, have certain advantages in some cases, the distances being longer perhaps and the lighting not so continuous. These may be considered, and are justly considered, as rival systems of lighting. They are both receiving our attention. We have plant specially contrived and manufactured in our works which is adapted to both these systems, and I think I may say it without any fear of contradiction that there is no company in London or on the Continent that can supply the plant for either of these purposes which we can at Belvedere-road Works. Before I turn to the figures, about which, of course, I desire to say something, there is another subject to which I would make some allusion—very unwillingly, however, as I do not like to discuss a matter before the law courts; but I think you may fairly expect, and will expect, that I should say something with reference to the pending litigation. Of course the pending litigation is a very important matter. You may be quite sure it has never been absent from our minds during the past twelve months. At the same time you must not overlook the fact that the exact character of that litigation is not so important to us as it is to our antagonist. What we have at stake represents barely a tenth of our business. What the Edison and Swan people have at stake represents the whole of their business. At any rate there is a monopoly. Therefore I say that we can regard this matter with more calmness, perhaps, than our antagonist. It is not a matter of vital importance to us. We can get on without making lamps. We have another very large business, which is increasing by leaps and bounds, and which I venture to say in the course of 18 months or two years will surprise you all. For that reason I myself—and I think I can speak for every one of my colleagues—regard this litigation without any anxiety. Well, there is another reason why we can regard that litigation, I think, without overwhelming anxiety, and that is that we are confident in the justice of our cause, and we have very considerable confidence in the final issue. Of course litigation is an unpleasant thing to be connected with, and I can say from my own experience that it is a thing that I am absolutely unacquainted with. I have always made terms as to any matters personal to myself with any gentleman who attempted to get me in any way into litigation, and I should always pursue the same course in affairs connected with any company in which I happened to have a voice. But the present case is an exceptional one. We were met by people who contested the value of patents for which you paid a very large sum. We could not act according to what might have been our desires and wishes if it had been a private matter. We took the opinion of the best counsel, and that opinion was that we had a good case, and that we ought to fight it to the utmost. We have fought it as far as it has gone, and the result has been one way in one court and the other way in another court, and we are now in a perfect see-saw. The uncertainty of the law has long been a proverb, and it has been well exemplified in this case. The judgment of Mr. Justice Kay was considered at the time to be a very good decision. The case, however, went to the Court of Appeal, and his judgment was reversed. We have now notified our intention of taking it to the House of Lords, which is the highest court of appeal in the country. I do not know that when we get the decision of the House of Lords it may be final in this case, for reasons that I need not enter into now. At any rate, we felt that we had no alternative but to stick to our guns and go to the House of Lords. My own personal feelings are always in favour of making terms with your enemies while you are in the way of meeting them, and the Board has never neglected an opportunity of approaching the opposite side in the most conciliatory spirit, and with every desire to meet them half way, or as far I am sure as any gentleman in this room could desire. I am bound to say that our antagonists have not shown the same desire to do so, or at any rate the same conciliatory feeling. On the contrary, they have manifested a desire to continue this suit, and to really put us—if I may use the expression—to every inconvenience in their power. They may be all right, and justified in a thing of this sort, their position being, as I said before, different from ours. The law-suit being a vital one to them, it is hardly possible for them to approach it with the same calmness and independence as we can ourselves. However, I can assure you that while we have deemed it our duty to take this matter to the House of Lords, still we are open to be approached by the Edison and Swan people at any moment. We are willing to make terms with them so as to save your interests and to save your honour in any reasonable way that can be suggested, and I am not without hopes that before the interval which must elapse before this case can be heard in the House of Lords that something may be done in the way of arriving at a conclusion satisfactory to both parties. Beyond that I need say very little on that point. We have one other case pending at present. It is the case against Messrs. King, Brown and Co., Edinburgh, in reference to the compound winding. You know that we have a claim to have the controlling of the patents for compound-winding of dynamos. That has been admitted by all the English makers, and they are now paying us a royalty which amounts to a nice little income to us. But the firm I have mentioned have contested that claim, and have carried the matter to law, and the case is still pending. Under these circumstances I will not depart from the proper rule of not expressing any opinion on the merits of the case beyond what I have said. Now, I think you will permit me to turn to the accounts, which are as satisfactory as the report. Indeed, one cannot be satisfactory without the other. You will have noticed that these accounts and report have been accompanied by a diagram. This is somewhat unusual, perhaps, but we considered that it was perhaps the readiest way of bringing the facts to the comprehension of the shareholders—to show to what an extent the volume of business has increased, to what an extent the gross profits have increased, and to what an extent the general charges have decreased or remained stationary. I think that that document is a very remarkable paper. You will see that in the five years from 1883 to 1888 the volume of business has increased from 100 to 307, or over 200 per cent. in five years. You will see that during the same period the gross profits have increased 242 per cent. That I think is very remarkable, and I think I can fairly challenge any electric lighting company in the world to show similar results. And we have still one strong feature to dwell upon, and that is that the general charges have hardly increased at all—have not only not increased in the same ratio, but have, if anything, shown a tendency to decrease. That can be only due to one thing—to improved management. Economy has been introduced by our able manager, Mr. Garcke, into every branch of his administration. Our general charges have fallen from 100 to 65 per cent. I challenge any other electric lighting company in the world to produce an equally satisfactory diagram in the last five years' working. To turn to the profit and loss account for this year, you will see that the gross profit on the year's transactions and trading amount to the very respectable figure of £23,049, a result which I think very encouraging. To this we have to add the balance carried forward from last year of £2,562, making the available balance £30,612 carried to general account. I think I ought to point out that the standing charges show only an increase of 7 per cent., while the business has increased 50 per cent. during the last 12 months. Turning to the balance-sheet you will see that the share capital has been increased by the issue of 1,160 new shares. Those shares were issued for the purpose of increasing our working capital, which, as I think you may well imagine, we had every desire to do by every legitimate means, to enable us to undertake the large contracts which are daily being placed before us, and which we naturally are loth to send away to swell the business of our competitors. When I speak of our competitors in the trade, I think it may be interesting to you to know that we have not

Digitized by Google

had all to ourselves this prosperity and increasing prosperity of electrical business. If you consult "*The Electrician*" *Electrical Trades' Directory*,* you will find that in 1883 there were only 57 electrical engineers carrying on business in the City of London. You will find that in 1885 that number had increased to 101, and by 1887 it had increased to 156, and by 1888, you will find that it has advanced to 260. In six years the number has increased therefore from 57 to 260, so that we have not had the field to ourselves in London and the country, and when I say London and the country the difference is not very material, because a very large number of those country houses have also their London establishments. Firms in Manchester, Birmingham, and other large towns have generally their London houses as well. No doubt the competition will be increasingly severe, but when you regard what we have been able to do during the last twelve months, I think you need not despair of our holding our own in this industry in the future. If you turn to the creditor account of our balance-sheet you will see the patents practically standing at the same figure. They are slightly raised by additional patents which it has been our duty to take out, and by certain other charges incidental to the up-keep and maintenance of our patents and for the purpose of making them more valuable. From time to time it is possible to improve the patents by the expenditure of a small sum of money, and we should be blind to our own interests if we failed to avail ourselves of those opportunities as they occurred. That accounts for the trifling increase at which our patents stand at the present day. I said last year that I considered these patents stood at a low figure in our books, and I challenge any electric lighting company to show patents of equal value standing at so low a figure. I do not know that I need deal with the other accounts. Property and stock have been valued and stand at about the usual figures. We are owed, you will be glad to see, for work done over £46,000, that is, after deducting a certain margin for what are called bad debts; but I am glad to say that we make very few bad debts. We have had considerable experience in this, and we find that our estimates have been remarkably well realised. The present debtor balances due to us are £48,531, whereas we owe our creditors—trade-people and others—only £22,120, which is a highly satisfactory state of affairs. There is a suspense account which is the next item. That is for charges and expenses in connection with litigation. We considered how to deal with that, and consulted our auditors and legal advisers, and we came to the conclusion that it would be manifestly unfair to put that, while the law cases are still *sub judice*, to profit and loss account. It may turn out that the expenses will be largely paid, if not entirely, by the other side; but, on the other hand, it may happen that we should have to bear the brunt of the expenditure ourselves. There is an element of uncertainty about the subject that makes it necessary to deal with the item in this way. Against it, however, on the other side you will see provision account of £17,816, which is practically able to meet it should the worst come to the worst. That provision account is not represented wholly by money in the bank at the present moment. It is employed in our business. It is represented partly by stock, partly by plant, and partly by some of those debtor balances which are due to us from our customers. It is a satisfactory feature of these accounts to know that we have made provision for the worst that can happen supposing our anticipations are not fulfilled. Therefore it is not necessary to allude further to them. I do not know that I need trouble you at the present stage of the proceedings with any further remarks than to say that I consider that the result which has been achieved has been achieved by the continuous and united efforts of your officers, and in some directions by the enhanced efficiency, combined with economy, which not only the Board, some of whom take the greatest interest in and have the greatest technical knowledge of your affairs, but your general manager, Mr. Garcke, your superintending engineer, Mr. Raworth, your consulting technical adviser, Major-General Webber, and Mr. Sellon and Mr. Mordey, your electricians, have shown. To every one of these gentlemen your thanks are due for the results achieved.

You stand to-day with a realised profit equal to 5 per cent. dividend on the whole of the share capital of the company. It remains for you to decide this morning what you will do with the money, whether you will put it in your pockets as a 5 per cent. dividend for the whole of the twelve months or whether you will adopt the more prudent course which we undoubtedly recommend of leaving it in abeyance until the litigation is over. I have no doubt in my own mind that that is the wisest policy to pursue. It is the course that has been followed by our opponents, the Edison and Swan. They had a large balance of profit in their last year's books. They did not distribute it among the members. They held it in abeyance to meet eventualities. I think it would be unwise for us not to take the same prudent course. But if you should differ from the feelings of the Board on this point, it is undoubtedly within your option at the present moment to have that money as dividend, and divide the profit of £12,885 which stands to your credit. I have only one thing more to say, and that is that this business has increased, and is increasing very rapidly. I consider that we have overcome our difficulties of manufacture. We have undoubtedly further improvements and economies to effect. It is impossible to go on manufacturing from day to day without perceiving opportunities of manufacturing under more economical circumstances. We might follow the example of some of our friends, and take our works into the country, where labour, and coal, and other things are considerably cheaper, but then there would be the expense of removing and other drawbacks. We may pursue that course a little later. For the present we are satisfied to remain where we are, because while there are some objections to carrying on business in London there are incidental advantages. No doubt visitors from the Colonies with whom we do business feel it a satisfaction to see our works and the class of our machinery without the necessity of going into the country, and therefore it is much more convenient and remunerative to us to give them that opportunity instead of our having to take them into the provinces. I feel that by having our works in London we obtain orders—many of them large ones—which we should not obtain if our works were situated 100 or 200 miles from the metropolis. For these reasons a move into the country is not to be lightly undertaken, but it is a subject that we have been carefully considering, and we shall continue to do so. What I was coming to, however, is this—our business is increasing, and it is equally necessary that our capital should increase in a corresponding manner. We have got every shilling in the business that we are able to put into it. We have got this provision account in it of £17,816, we have got a certain amount of £12,885 in it, and we have got nearly £10,000 at the bank. Of course, you see, we owe our creditors £22,000. It might be possible to increase the present figure, and carry on a larger business with much greater liabilities. But you know what that means. To carry on the business remuneratively in the future, and to be able to watch its growth with equanimity, and to derive the exact and proper advantages from it, it will be necessary for us and for you sooner or later to largely increase our capital. There is another reason why that is necessary. Look at those other companies that are doing business in the same way—two or three lighting companies that have been recently formed in London with their millions of capital, such as the London Electricity Supply Company, and one or two others that I need not mention. You know how they go to work with a million or two of money. They have the means of raising that capital, and no doubt if we are to compete on fair terms or equal terms with these companies in the course of time, we must have our millions too. We have not seen this thing going on without seeing the necessity that would naturally arise if it proved profitable (and we have proved that to a greater extent than our competitors) of increasing the capital, and when the time comes, and it will be before long, when we shall have to go to the public for an increase of capital, I am quite sure that there will be a large number of gentlemen who will respond to our demand. I have nothing to add to what I have said except to thank you for your continued confidence in myself and the Board with which I have the honour to be associated. We shall continue to the best of our ability to work for you as well as we can, and we hope to justify the continuation of that confidence which has been hitherto extended to us, and without which I feel, for one, it would have been impossible for us to have brought this business to the satisfactory position it now occupies. I beg to move—

"*That the report of the Directors and statement of accounts to the 31st December, 1888, now presented to the shareholders, be received and the same be hereby adopted.*"

Mr. JOHN SCUDAMORE SELLON (the Vice-Chairman): Gentlemen, in seconding the resolution which has been put before you it will be unnecessary for me to amplify in any way the remarks of the Chairman, in which he has so fully referred both to the prospects and to the general business of the Corporation. From those remarks you will, I hope, have arrived at the conclusion that a really substantial improvement has now taken place in the prospects of the electric lighting industry, and that, so far as our Corporation is concerned, we are certainly not in arrear of those developments. I beg to second the resolution.

Mr. WEIR thought the shareholders had reason to congratulate their noble Chairman for his successful efforts in Parliament. With reference to paragraph 8 of the report, with respect to the establishment of a better understanding among the various electrical manufacturers and contractors, he hoped that did not mean that the price of electric lighting was to be increased, because the gas companies would no doubt like to find the electric lighting companies allying themselves together to keep up prices. Their object should rather be to keep prices as low as possible in order that they might be able more successfully to compete with gas. The gas companies were making reductions all along the lines. The report stated that "the royalties now received constitute an important source of revenue." It might or might not be convenient to state the amount of royalties actually received; he would leave that to the decision of the Board; but if not inconvenient it would be interesting if the shareholders could be supplied with the information. He was very glad to hear from the Chairman that the Board were anxious to compromise wherever there was an opportunity of doing so, for in matters connected with patents one could not show too conciliatory a spirit. Of course, the Directors had been advised to contest the matter; but lawyers usually gave advice of that sort. He trusted, however, that the Board would compromise the matter if they could do so without sacrificing the interests of the shareholders. He thought it would be unwise to distribute any portion of the profits in hand at present.

Mr. CURRIE: Is there any objection to informing the meeting the period at which the appeal to the House of Lords is likely to come off?

A SHAREHOLDER: I have the misfortune to be a shareholder both in this Company and in your opponent, and I may say that I heard the Chairman of the other Company make almost identically the same remarks that our Chairman has made to-day. He was anxious, he said, that the matter should be settled without litigation, and yet this case goes on.

The CHAIRMAN: If there are no more questions I will endeavour to answer the few that have been put. There is no difficulty about answering them at all. With reference to the compound-winding royalties, of course they appear in our accounts, and they come to a substantial figure; but it would not be expedient, as the action in Edinburgh is still pending, and the whole matter is still *sub judice*, for me to state the exact figure at which these royalties stood during the past year; but I can assure you that they stand at a very respectable figure, and at an increasing figure; and that we have very great hopes that they will prove a substantial source of revenue during the remainder of those patents. I hope the shareholders will excuse me not being more explicit in reply to what is a very natural question to know, exactly what those royalties stand at. I think you may take that as a prudent course to pursue. Then with reference to the figures at which the stocks stand in our accounts, it is very little beyond what the same time

[* This Directory is published at the office of *The Electrician*, 1, Salisbury-court, Fleet-street, E.C., and the (7th yearly) issue for 1889 is just published.—*Publisher's Note.*]

Digitized by Google

stood at in our last year's balance-sheet, and there is an undoubted tendency in that item to decrease in size. You must recollect that the volume of business we are doing now in comparison with the volume of business we were doing last year or the year before is very much greater; but you wil find that the stock practically stands at almost the same figure. You must also remember that we do a great deal of business which necessitates the keeping of a large amount of stock on hand, for exhibition lighting for instance. We have done a successful general lighting in nearly all the great exhibitions of late years—the Melbourne Exhibition, the Glasgow and Manchester Exhibition, and other places. At Barcelona, also, we have been very successful, and we have one or two other places on hand. We expect to have a considerable slice of the Paris Exhibition next year; we have practically got a contract for a considerable slice already. All this entails having a considerable amount of plant ready to send out at a moment's notice to the Colonies or elsewhere. The plant does not deteriorate, and when it goes to the Colonies it very seldom comes back. In the case of the Melbourne Exhibition, I should not be surprised if none of it comes back. We have sold a great deal of plant already in the same way at Barcelona. We have sold a great deal of the plant that we have sent out to different places, but if we had not had it ready to send out, at a moment's notice almost, we should not have made a profit; but the item will, I think, always tend to show a decreasing figure relatively to the volume of the business we have to do, and in the meantime it only stands at cost price in our books. Then, with reference to when we may expect this case to be heard by the House of Lords, of course it is impossible to fix the precise date, although it will very likely come off in the course of four or five months. Still, it may not come off for twelvemonths. It depends upon the arrears of work in the House of Lords, which are not anything like so heavy as they used to be. It depends greatly on the parties themselves. If they desire a postponement for the purpose of prolonging negotiations there would, of course, be a delay. It is really impossible to answer the question, except by saying that it is bound to be heard practically within twelvemonths if it is heard at all. But I heartily share the hope expressed by two or three of the shareholders that it will not come to that at all. If it does, we are confident of the result; but we have every desire to compromise on fair and honourable terms; having regard to your vested interests, we cannot throw your property away; I do not think you would wish us to do so. If we did you could bring an action against us for so doing. While, therefore, we have every desire to be conciliatory, and are prepared to settle on some terms, we are not prepared to settle on any terms. It therefore remains for the other side to show an equally conciliatory feeling before anything can be accomplished. Up to this moment there has been much more desire to settle this matter in an agreeable and friendly spirit manifested by us than by our antagonist the Edison and Swan Company. Of course we never know what that may be owing to. Some people think they impress others more when they assume a sort of dictatorial tone; but we do not think that. We are honest, straightforward people, and we speak to Mr. Forbes as I speak to you. We have every desire to settle it; but he comes and says "We have no desire to settle it; we are sure that we shall win;" but I cannot believe, for one, that that does not cover a certain amount of anxiety in his own mind when I know what it means to them. I hope, and think it very likely, that finally we may arrive at a friendly arrangement with them. Beyond that I have nothing more to say, except that I cordially hope it as much as any of our shareholders.

The motion was then put and carried unanimously.

Mr. SELLON: Gentlemen, I beg to propose the election of two directors in the place of those retiring, and the names that I will put forward are those of the Right Hon. Lord Thurlow and Colonel Steuart. Lord Thurlow's name in connection with electric lighting is, as you all know now, a household word, with which is connected the Electric Lighting Act which we so ably pioneered through the House of Lords and then through the House of Commons last year, and without which we should still be in a "slough of despond." Colonel Steuart has, from the first institution of this Company, been one of its hard-working and indefatigable Directors, and to those who can judge of the anxiety and work that this has entailed, I think I need urge no further reason for his re-election. I beg to move

"That the Right Hon. Lord Thurlow and Colonel Frederick G. Steuart be re-elected Directors of the Corporation."

Mr. COPLAND seconded the motion, which was carried.

Mr. COPLAND moved the re-appointment of Messrs. Cooper Bros. and Co., as auditors,

Mr. BLESSLEY seconded the motion, and it was also carried.

Mr. WEIR: Gentlemen, before we part I beg to propose a hearty vote of thanks to the Chairman for his conduct in the chair to-day, and to his colleagues as well, for the way in which they have managed this successful pioneer company and brought it to a profitable issue. If you would allow me I would supplement that by adding the names of the officials to those of the Directors. I beg to move that.

Mr. HART: I shall have very great pleasure in seconding that vote of thanks.

The proposition was adopted.

The CHAIRMAN: On behalf of myself and my colleagues, I beg to thank you, gentlemen, for your renewed expression of confidence, and to assure you that in the year to come we shall endeavour to serve you as well as we have in the past twelve months, and we hope that the result will be still more satisfactory, and that we shall be able to meet next year and divide the profits.

The meeting then closed.

The Telephone Company of Egypt (Limited).

The sixth ordinary annual meeting of this company was held at the Offices, 14, Austin Friars, E.C., on Tuesday, 12th inst., under the presidency of General Fraser, C.B., R.E.

The following is the report of the directors:—

After writing off a sum of £227. 8s. 7d. for depreciation, and providing for interest and expenses incurred in connection with the issue of debentures, the net profit for the year is £4,025. 10s. 5d.; adding to this amount the sum of £665. 2s. 6d. brought forward from 1887, the balance available for disposal is £4,690. 12s. 11d. Out of this the Directors recommend a dividend of 6 per cent. for the year, on the Preferred shares, free of income-tax, which will absorb £3,621. 6s. 0d., leaving £1,069. 14s. 11d. to be carried forward.

The re-arrangements for the management in Egypt, consequent on the death of the late manager, Mr. A. D. Evans, have proved satisfactory, and the Directors were glad to have been enabled to entrust that office temporarily to his son, Mr. W. N. Evans, who has since been confirmed in the appointment.

The loss of revenue during the year through the withdrawal of subscribers and other causes has been fully met by the continued growth of the exchanges, the total number of subscribers in Egypt on the 31st December being 980, against 917 the previous year.

The extension from Cairo to Hélouan, mentioned in last report, has been established with satisfactory results.

Efforts have been made to open a small exchange at Port Said, and it is hoped that during the current year the work may be carried out; at present, however, the support promised is not sufficient to warrant the commencement of the undertaking.

The apparent increase of the working expenses is due to the fact that the whole of the wages and salaries of the permanent staff have during the past year been charged against revenue, the Directors being anxious, so far as possible, not to increase the expenditure on capital account.

In accordance with the notice in the last report the sanction of the shareholders was obtained to an issue of debentures not to exceed, in all, the sum of £20,000. Of this amount £5,000 were issued in Egypt, and the loan from the Oriental Company was paid off.

Under the Articles of Association General Fraser, C.B., R.E., the Chairman of the Company, retires from the direction, but, being eligible, offers himself for re-election.

Messrs. Price, Waterhouse and Co., the auditors of the Company, also retire, and offer themselves for re-election.

The SECRETARY (Mr. Alex. B. Chalmers) read the notice convening the meeting.

The CHAIRMAN said: I assume, gentlemen, that the report of your Directors and the accounts presented therewith may be taken as read. I may, on the whole, congratulate the shareholders on the continued prosperity of their undertaking in Egypt, and I am glad to be able to say that the management in that country has suffered no deterioration by the confidence we have placed in the late manager's son, whose assiduity and capacity bids fair to come up to those attributes of his late father. We have also been able to utilise the services of a daughter of the late manager, whose clerical ability and knowledge of accounts are considerable. Your Directors have, therefore, been able, with advantage to the Company, to place their late manager's family beyond pecuniary difficulty. It may, perhaps, be said that in carrying forward so large a sum as £1,069. 14s. 11d. we are erring on the side of caution; but it must be remembered that we have no working capital, and that we should have money in hand to start any fresh extension. We have, moreover, so far made no provision for the redemption of debentures, and a good balance in hand will give confidence to any further issue of these bonds which may be necessary to enable us to carry out any important extension. The continued prosperity of your business depends to a great extent on the continued prosperity of the country which is the scene of your useful labours, and we feel that we should always be prepared to enter upon any new field which may be open to us. We may hope for an increase of business, but we have also to face a constant desire to reduce the rates of subscription. From our commanding position we can do the work very thoroughly and efficiently, and the more thoroughly we do it the less fear is there of competition, and if by a considerable increase in our business the cost of our administration is spread over a larger area, we should no doubt be able to give our subscribers some share of the benefit to be derived from a smaller percentage of working expenses. It does not appear to me that we can be more economical in actual working than we are at present. Our staff in Egypt is thoroughly efficient, and your thanks are fairly due to Mr. W. N. Evans and his staff. Considering that gentleman's youth, we thought it expedient to give him the aid—voluntarily offered—of three gentlemen of experience and influence, who offered their assistance as a consultative committee in Egypt. These gentlemen were—Mr. T. C. Chapman (the P. and O. Company's agent at Alexandria), Mr. George Goussio, banker in Egypt, and Mr. Smith, the superintendent in Egypt of the Eastern Telegraph Company. In such esteem was the late manager held in the country that they came forward to help the son gratuitously, but your Board, having derived benefit from their generous assistance, has thought it fit to offer each a small honorarium, by means of which they should in no way be out of pocket. We have carried no very large sum to depreciation, because we think that as the working must be kept in perfect order, the renewals and maintenance charged against revenue fully compensate for any temporary deterioration of wires, poles, and instruments. There is nothing further which it occurs to me to say, but I shall be glad to answer any questions on the subject of the business before us. No question being asked, the Chairman continued, I beg to move—

"*That the report and accounts for the year ended 31st December, 1888, be and are hereby approved and adopted, and that a dividend be paid of 6 per cent. on the Preferred shares, free of income-tax.*"

Mr. HENRY GREWING: I beg to second that.

The motion was carried unanimously.

Mr. THOMAS LLOYD: I beg to propose—

"*That General Fraser, C.B., R.E., be and he is hereby re-elected a Director of the Company.*"

Mr. ADDISON seconded the motion, which was carried unanimously.

The re-election of the auditors, Messrs. Price, Waterhouse and Co., having been proposed and carried,

Mr. ADDISON moved—

"*That a vote of thanks be accorded to the staff in Egypt for the able manner in which they have conducted the business.*"

This was seconded by Mr. LLOYD and unanimously agreed to.

On the motion of Mr. ADDISON, a vote of thanks was then passed to the Chairman, and the meeting terminated.

The Direct Spanish Telegraph Company (Limited).

Report of the Directors to be presented at the half-yearly general meeting, to be held at Winchester House, Old Broad-street, London, E.C., on Monday, the 25th instant, at 12 o'clock:—

1. The accounts for the half-year ended 31st December, 1888, show, after providing for debenture interest, a balance to the credit of profit and loss of £5,720. 4s. 10d.

2. The traffic receipts show a decrease of £305. 4s. 11d. as compared with the corresponding half-year of 1887. The falling off in the receipts for last half-year is attributable to the slackness of the fruit trade, owing to the inferior crop of last year in Spain.

3. The working expenses are £95. 12s. 11d. less than in the corresponding period of last year.

4. The Company's cables and the land lines in connection with them have continued in good working order throughout the half-year. Unfortunately since the expiration of the half-year for which the accounts are now submitted an interruption of the Bilbao cable has taken place; the cable was, however, speedily restored, and has worked well since. The Directors propose that the cost of these repairs (£2,966. 10s. 7d.) shall be charged partly to reserve fund and partly to revenue.

5. After putting £2,500 of the balance of profit and loss to the reserve fund, which amounts to £13,660, there remains an available balance of £3,220. 4s. 10d. Out of this amount the Directors recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend at the rate of 4 per cent. per annum (free of income-tax) on the Ordinary shares, making with the previous distribution 4½ per cent. for the year 1888, against 4 per cent. in the year 1887. This will admit of a sum of £723. 5s. 3d. being brought forward to next account towards the payment of the portion of the cost of the repairs of the Bilbao cable charged to revenue. The dividend warrants will be issued on 1st April, 1889.

6. Sir James Anderson and Mr. Denison Pender are the Directors retiring by rotation, and, being eligible, offer themselves for re-election.

7. The auditor, Mr. Herbert R. Duke, retires, and offers himself for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The directors of this company on Wednesday declared an interim dividend of 3s. per share, being at the rate of 6 per cent. per annum, free of income tax, for the quarter ended December 31st, 1888, and payable on the 25th inst. The books of the company will be closed from the 18th to 23rd inst., both days inclusive. The traffic receipts for the week ended March 8th, 1889, amounted to £5,575.

DIRECT SPANISH TELEGRAPH COMPANY.—After transferring £2,500 to the reserve fund, the directors of this company, in their half-yearly report, recommend a balance dividend at the rate of 4 per cent. per annum, making a total distribution for the year 1888 of 4½ per cent.

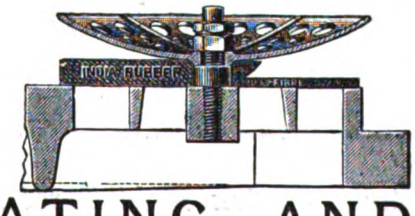
ORIENTAL TELEPHONE COMPANY.—The directors of this company on Wednesday resolved, subject to final audit of the accounts, to recommend to the shareholders a dividend of 3 per cent., free of income tax, on the paid up capital of the company (other than the vendors' shares), for the year ended December 31st last, placing £2,500 to reserve and writing off the whole of the balance of the preliminary expenses, amounting to £3,000, leaving an amount of some £500 to be carried forward.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 8th, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,401.

We learn that Messrs. Mix and Genest, the well-known Electricians, of Berlin, have sold their establishment to a group of banking firms with the view of transforming the same into a joint stock company.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL." "12, John-street, Sunderland, 26th Sept., 1885.

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 566.—Vol. XXII. FRIDAY, MARCH 22, 1889. Price Fourpence.

NOTES.

An important step has been taken by the Board of Trade in reference to electric lighting in the metropolis by the appointment of Major Marindin to hold an inquiry into the various schemes for which Provisional Orders and Licenses have been sought. The inquiry is to commence at 10:30 a.m. on Wednesday, April 3rd, at 8, Richmond-terrace, Whitehall. Some further reference to the matter will be found in another part of this issue.

The important Paper of Prof. J. J. Thomson "On the Resistance of Electrolytes"—an abstract of which we print in this issue—will be read with interest, not merely for its own sake but also because it affords the first illustration of the employment of one of the Hertz phenomena as an instrument of research—and a very powerful instrument it is seen to be. The Paper, which was received by the Royal Society on January 9, commences with a statement of the "theory of screening," and by a coincidence we published two days later the independent investigations of Dr. Fleming upon the same subject. The results arrived at—which it is needless to say are identical in each case—may be briefly expressed by saying that if a sheet of any conducting material be interposed between a primary and a secondary circuit of which the former conveys an alternating current (including, of course, an oscillatory discharge) the extent to which the secondary circuit is shielded from the induction of the primary depends directly upon the thickness and specific conductivity of the screen, and inversely upon the frequency of the primary current. Prof. Thomson, therefore, took two horizontal circuits whose time constants were equal, and in one of which very rapid electrical oscillations were established, and between them he interposed a horizontal tray in which various electrolytes could be placed. The particular thicknesses of the liquid strata which effectually screened off the electric radiations are proportional to their specific resistances, so that the method affords a means of directly comparing the relative resistance of different electrolytes with currents of very different frequencies. It is evident that the great advantage of the method consists in the absence of electrodes, the currents in the electrolyte being of the nature of Foucault currents. Prof. J. J. Thomson concludes from the experiments that "the relative resistance of electrolytes is the same when the current is reversed a hundred million times a second as for steady currents." Further interesting experiments are detailed in the Paper.

At the Royal Society yesterday (Thursday) afternoon Mr. Shelford Bidwell communicated an experiment which, to all appearance, affords evidence of a direct action of light upon magnetised iron. We print on another page an abstract of the Paper, from which it will be seen that the success of the experiment is largely due to the use of iron specially prepared, so as to be in a condition of magnetic instability. When a beam of light is thrown upon such a piece of iron its magnetic condition undergoes an almost instantaneous change. The experiment is one of great beauty and suggestiveness. Mr. Bidwell is now engaged in following up this line of research, so as to ascertain if possible the exact nature of the effect.

The very adverse report of Prof. Forbes upon the durability of the lead-covered cables in Berlin naturally created something like a scare amongst the users of this class of wire in this country. According to the information furnished to Prof. Forbes the life of a cable insulated with a bituminous compound and lapped with lead—such as is supplied by Messrs. Siemens and Halske—when buried in the soil cannot be taken to exceed three years. If this be absolutely true it is most desirable that the fact should be fully understood. The statement is the more surprising since the durability of lead when buried in the soil has hitherto been an article in the creed of most electricians. Mr. Preece, speaking last week in the discussion on Prof. Forbes' Paper, mentioned the well-known case of the pneumatic tube laid in 1854, he also exhibited a piece of lead-covered cable still in perfect condition which had been buried ten years earlier. But valuable and reassuring as this evidence undoubtedly is, we should like to ask whether any instance of failure similar to that described by Prof. Forbes has ever come under the notice either of Mr. Preece or of any one else; if so it would be of great value to know the exact conditions under which the deteriorations occurred.

In respect of the alleged failure of the Siemens concentric cables at Berlin, Mr. Alexander Siemens was able to make a statement of a reassuring tendency. It appears that these cables gave no trouble until towards the end of last year, when the leads of the three central stations were all connected in parallel. It is true that prior to this an occasional fault had occurred—almost invariably due to mechanical injury—but the daily insulation tests had sufficed for its discovery and localisation before it had developed to anything like serious

Digitized by Google

proportions. Since, however, the leads were joined together it has no longer been found possible to take insulation tests, and when the cable has suffered damage the fact has remained undiscovered until something serious has taken place. This state of affairs has given rise to considerable friction between the Allgemeine Electricitats Gesellschaft and Messrs. Siemens and Halske, and as Mr. A. Siemens explained, Prof. Forbes happened to visit the installation at a time when the friction was at its height, and, doubtless, he heard the worst that could be said for the cables. We do not, however, believe that the testing of the cables for insulation under the above conditions is absolutely beyond the resources of electrical science, although, doubtless, the localisation of a fault will be more troublesome than before. We have several times called attention to the excellent results obtained at Brooklyn with cable coated with lead to which a small proportion of tin is added. We do not understand why this alloy has not been brought into more extensive use in this country.

The project of holding a "convention" of telephonic engineers—as suggested by our contemporary *The Telephone*—is one to which we are prepared to give the fullest approval. From a purely technical standpoint it is impossible to doubt that much good would follow from the mutual exchange of advice and experience amongst telephone engineers. At the same time we are well aware that this view does not find favour amongst the directors of the *haute politique* of telephony. In its various discussions on matters telephonic the *quondam* Society of Telegraph-Engineers listened in vain for the voices of the engineers and electricians of the telephone companies. More than this, we happen to know that when Papers have been offered to the Society by the *employés* of provincial companies, and with the consent of their directors, the parent company has stepped in and secured their withdrawal. Such having been the policy hitherto adopted, it will afford us the greater pleasure to learn that the United Telephone Company has now been converted to more enlightened views. If, however, the consent of the parent company be not obtained, we very much doubt whether the convention could be successfully held.

We understand that the negotiations for the amalgamation of the Telephone companies are now so far advanced that a definite announcement may be expected at a comparatively early date. The present scheme includes only the United, the National, and the Lancashire and Cheshire Companies; but if these three giants can arrive at an agreement they will probably find little difficulty in dealing with their weaker brethren. We may add that in anticipation of eventual combination the National Telephone Company for some time past has laid out and constructed its trunk wires with a view to their ultimate junction with the metropolis. Meanwhile the London-Birmingham wire is making but slow progress, and we note also that in a recent number of our contemporary, *The Telephone*, the wisdom of employing so small a gauge as 12½ (hard-drawn copper) is severely criticised. In any case, it is to be hoped that this line has been considered merely as the first link in the chain of through communication to the Midlands and the North. If it has been designed merely with a view of speaking to Birmingham and no further, we think a serious mistake has been made.

The Paris Municipality, whilst seeking to foster the employment of central station plant during the hours of daylight, has been led into a most extraordinary blunder. According to the scale of charges just promulgated, the supply companies are instructed to charge so much *per carcel-heure* (!) for light, and so much per horse-power hour for motive power. It is quite unnecessary to enlarge upon the sheer absurdity of a photometric tariff; but as if the decree was not already sufficiently ridiculous, the prices have been arbitrarily fixed at 0·45fr. per horse-power hour, and 0·045fr. per carcel-heure. Now, as our contemporary, the *Revue Industrielle*, justly observes, at this rate it would, as a rule, be cheaper to obtain light by the use of a motor coupled to a dynamo rather than to utilise the current directly in the lamp. This edict is in fact a fine example of municipal electro-technics.

M. Popp is, of course, well known as the advocate and the successful introducer of the system of distributing energy by means of compressed air, and, as we have from time to time made note, his station at St. Fargeau already supplies power for a considerable amount of isolated electric lighting plant in the centre of Paris. We understand that for the purpose of lighting the important district which has been allotted to him some 9,000 horse-power will be added to the existing engines at St. Fargeau. A special air conduit 30 centimetres in diameter and 8 kilometres in length will be laid down, and from this a number of sub-distributing stations will be fed. Our Paris correspondent mentioned last week that accumulators were to be employed, but we note that *L'Électricité* credits M. Popp with intentions of a much more remarkable character. According to this authority each sub-station is to be equipped with a compressed air engine driving a continuous-current dynamo, which, by means of a special commutator, supplies alternating currents to a primary transformer, which is to feed secondary transformers at the subscribers' houses. Well may our contemporary exclaim, "*Que de transformations!*"

We are glad to learn that the number and character of the applications already received by the Birmingham Electrical Exhibition Committee are such as to assure the complete success of the undertaking as a representative collection of the appliances of modern electrical engineering. One feature of the Exhibition will be that, outside the dynamo department, the whole of the motive power will be supplied by electro-motors, and notwithstanding the large number of entries in this class the committee have already found it necessary to obtain additional machines, in order to furnish the power applied for. In respect of electro-motors, the show will certainly be unique, and the committee are also anxious that it should include as many different types as possible. An equally important feature will be the display of central station outfit, and it is hoped that an opportunity will

Digitized by Google

be afforded of examining and comparing every system of electrical distribution which is to be found in operation.

We understand that the Metropolitan Electric Supply Company has taken over the small central station in Berners-street, Oxford-street, which was started about a year ago as a private speculation by Messrs. Pritchett and Co. The plant at present in use consists of two 80 horse-power Mordey alternators, which furnishes current to Mordey transformers, supplying about 1,500 16 candle-power lamps. This station has worked with perfect success from the very first. We believe, however, that in the further extensions which are contemplated by the Metropolitan Company plant of the Lowrie-Parker type will be installed.

From the annual report of the London Chamber of Commerce for the year 1888, which has just appeared, we gather that, whilst the thirty-five Trade Sections and General Committees of the Chamber held between them 153 meetings, or an average of 4·4 apiece, the Electrical Section, in the first three months of its existence, held no less than eleven meetings, or an annual rate exactly four times greater than the average. The report mentions incidentally that the Section is now also one of the strongest numerically in connection with the Chamber. The work hitherto accomplished is referred to in the following terms:—

"The first practical step taken by the Section consisted in drawing up a series of recommendations defining the relations of supply companies with local authorities in regard to licenses or provisional orders, and amongst the subjects with which it was considered desirable to deal were the following:—Uniform method of charge by undertakers; infringement of patents; increase of Board of Trade unit; supply companies control of wiring houses in their districts; overhead wire regulations; the position of the trade in relation to the Electric Lighting Act; Board of Trade regulations and accounts (in regard to which some progress was made before the end of the year); agreement between the electric lighting firms and insurance companies, and between the firms themselves, to determine the fundamental requirements in all cases and to avoid favouring; Board of Trade regulations as to testing mains and meters; proper inspection of work on electric lighting installation in connection with fire risks; Tramway Act; recognition of electrical standards; reports on exports, markets, customs duties, railway rates and share quotations; fire insurance rules; standard specifications; and standard types of apparatus. Some of the foregoing matters have already engaged the attention of the Section, and a satisfactory result has been recently attained in the adoption by the Board of Trade of a unit of 10,000 watt-hours, instead of 1,000 watt-hours as heretofore—a change which the Section has strongly advocated."

We may add that the March meeting of the Committee of the Section has not yet been held, owing to unavoidable causes. We anticipate that the Committee will shortly call a meeting of the whole Section to report progress.

In reference to the process of tanning leather by the aid of electricity, of which we have spoken lately, a contemporary journal—*The Shoe and Leather Reporter*—is delivered of the following sapient pronouncement:—

"Notwithstanding the signal failure of electricity in refining sugar, we still hesitate to pronounce definitely against the efficacy of this new element in forcing the tannin in the gelatine of the hide."

To which we would in like manner rejoin that, notwithstanding its signal failure to comprehend the exact nature of the relations between electricity and sugar, we are free to admit that our contemporary is a useful and respectable publication in its own particular walk of life.

Copper has been sold this week as low as 35, and was quoted yesterday at 40 to 42.

"The Electrician's Paper."—An electrical journal, called *The Electrician's Paper*, is now being published at St. Petersburg.

Teddington.—The new church at Teddington is to be lit by electricity, the current being supplied from Earl Russell's house close by.

Exeter.—It will be seen by our advertisement columns that the directors of the New Theatre Royal, Exeter, invite estimates for the electric lighting of this theatre.

Sale of the Elieson Plant.—The sale of the patents and plant of the Elieson Electric Company will take place on Wednesday, April 17th, at Plashet Hall Works, Stratford.

Chelsea Electricity Supply Company.—The work of drawing in the cables belonging to the Chelsea Electricity Supply Company has now begun, and the light will be supplied to the residents who have had their houses wired in a few weeks time.

Chelsea Vestry.—At a meeting of this Vestry last week, the Electric Lighting Committee reported recommending that the Vestry assent to a proposed extension of the area of supply by the Chelsea Electric Supply Company. The report was adopted.

Reduction of Tariff to South America.—The Brazilian Submarine Telegraph Company announces that, on and after the 1st April, a reduction of rates to South America will be made, of which full particulars will be found in our advertisement pages of last week's issue.

Electric Traction at Brussels.—The experiments with electrically propelled tramcars which took place during the past year at Brussels, and which yielded somewhat unsatisfactory results, will be renewed shortly in the Rue de la Loi. This part of the line includes a very steep incline, and if the present trials are satisfactory it is probable that the system of electric traction will be adopted on all the lines.

The General Electric Company.—We have received from the General Electric Company (G. Binswanger and Co.) a copy of the seventh edition of their illustrated catalogue of electric bells. This catalogues has been considerably enlarged, and now contains some 55 pages and over 260 illustrations. Full descriptions with prices are given of a large variety of batteries, bells, pushes, and almost every requisite of domestic electricity.

Specific Resistance and Temperature Coefficient of High Resistance Liquids.—Those of our readers who have occasion to make determinations of the above will find a handy form of apparatus described in the *Centralblatt*, Vol. XI., No. 1, by Dr. J. Otten, who also points out a source of error due to the slow contraction of the glass tube form of containing vessel which occurs for some hours after working.

Ohm Memorial Fund.—The contributions hitherto paid or promised in this country towards the intended statue of G. S. Ohm amounts to £95s. 14s. 6d., from 94 subscribers. It is proposed to close the subscription list at the end of the present month, and we are desired by the committee to ask intending subscribers to send their contributions as early as convenient to the Treasurer, Dr. Hugo Müller, F.R.S., 13, Park-square, N.W.

Electrotherapeutics.—A series of experiments on the mode of diffusion of voltaic currents in the human body has led M. L. Danion to the following conclusions, which were published in a recent number of the *Comptes Rendus*. With the exception

Digitized by Google

of the skin and the bones, the various constituents of the human frame have practically the same resistance. The resistance of the bones is 2½ times greater than that of the hypodermic tissues.

Law Courts Branch Bank of England.—We understand that the electric light installation at this bank is now completed and running well. A total of 220 lamps have been fixed throughout the bank and agent's house, the current for which is obtained from a 12-unit Elwell-Parker dynamo driven by a Crossley gas engine. The battery was manufactured by Elwell-Parker (Limited), to the specification of Messrs. Drake and Gorham, who carried out the installation.

Long Distance Telephony.—In the *Electrotechnische Rundschau* for March will be found an article by Dr. Wietlisbach, of Berne, on the above subject. The article is too long to reproduce in full, but the author comes to the following agnostic conclusions:—"There is, up to the present day, no formula known which will give the limiting distance for telephone work with any approach to accuracy; no reliance can be placed on data obtained from any experiments yet made; the limit for overhead copper lines has never yet been reached."

Telephone Call Rooms in London.—In addition to the twenty-four call rooms at present available in London, the United Telephone Company will this month open additional rooms at Richmond, Willesden Green, Kew Bridge, Forest Gate, Shepherd's Bush, Norwood, and Lewisham, and preparations are being made for stations at Streatham Hill, Brixton (second), Sydenham, Hampstead, and Leytonstone. Subscribers make use of these call rooms free, and non-subscribers at a charge of sixpence.

The Lighting of the House of Commons.—It appears that the addition of the electric light to the arrangements of the House of Commons has increased rather than decreased the expenses for gas. Last year the gas bill was £3,300, whilst the cost of the supply for the coming year is estimated at £4,000. This is in addition to an increase in the expenditure on electricity of £40. The supply of oil lamps in the Houses of Parliament still maintains its immense proportions. This year as last not less than £2,000 is paid for oil for the lamps.

Medical Electricity.—The Société Médicale de Bruxelles has offered a prize of 2,000fr. for the three best Papers upon the following subjects:—1st. The measurement of the electric currents in the animal tissues. 2nd. The measurement in ohms of the resistance offered by liquids and tissues in living organisms to feeble currents. 3rd. A review up to date of the works on, and researches into, the theory of electric endosmose and its application to the phenomena of secretion in living organisms. The papers must be sent to Dr. Stienon, Rue Horn, Brussels, before January 1st, 1890.

St. Alban's.—At the last meeting of the St. Alban's City Council the following report was read: Your committee who were appointed to inquire as to the probable cost of lighting the city by electricity, beg to report that they have made inquiry as to the probable cost of establishing and maintaining electric lighting works in this city, and are of opinion that no reliable estimate can be obtained except at considerable cost, and under these circumstances they recommend that they be discharged from further prosecuting the inquiry entrusted to them. It was agreed to dissolve the committee.

Dorchester.—An application was recently made to the Dorchester Gas Company by the Town Council for a reduction in the charge for the public lighting. The directors, in reply, reminded the Council that the terms of the contract of 1887 were approved of by the Corporation, and as the cost of producing gas is the same now as it was then, they could not see their way to making any alteration in the price. After some discussion, it was resolved to apply to an electric light company to furnish an estimate for the supply of the light. It was also resolved to inform the Gas Company that the Council did not consider the letter satisfactory.

The Post Office Telegraph Service.—An estimate of the additional amount required in the year ending March 31, 1890, to defray the salaries and working expenses of the Post Office Telegraph Service, in consequence of new arrangements for working the submarine telegraph cables between England and Belgium, France, Germany, and Holland, was issued a few days since. The gross total of the estimate is placed at £60,050, against which there is to be set off the sum of £10,150 constituted by receipts from the telegraph administrations of the aforesaid Continental countries for one-half the cost of maintaining the cables. The net total is, therefore, £49,900.

Electric Meter Competition in Paris.—The decree of the Prefet de la Seine authorising the long-talked of meter competition has just been published, together with the programme. The meters and sketches must be left under seal between the 15th and 25th May at the Hotel de Ville, Paris, at the office of the Sous-directeur des Travaux. The programme of this competition will be found in our issue of January 18th, p. 299. A sum of 20,000fr. will be distributed among the successful competitors, viz., 10,000fr. to the inventor who produces a meter giving complete satisfaction, five premiums of 2,000fr. to the designers of the five next best meters, half the above sums being awarded if the meter can only be used with one kind of current.

Chester.—Last Friday week a meeting of gentlemen interested in the formation of a central station for the supply of electricity in Chester was held at the Town Hall to confer as to the expediency of introducing the electric light into the city. Mr. T. V. Hughes, an electrical engineer of the city, said he had canvassed the neighbourhood, and had received promises for about 300 lights from several of the more prominent citizens, and this being so, they had prepared an estimate on that basis. Mr. Manville subsequently addressed the meeting, entering into many details in connection with the proposals. A desultory discussion followed, and in the end Messrs. Hughes and Manville were requested to prepare a circular giving information as to cost, &c., of a central supply station.

The Cable to Morocco.—The following telegram has appeared in one of the daily papers:—"For some time past the Madrid Press has been publishing reports from Morocco to the effect that the cordial relations hitherto existing between the Sultan and the British Legation at Tangier were disturbed, because the Moorish authorities are said to oppose the repair and re-establishment of the British cable between Tangier and Gibraltar which the Sultan had authorised only a year ago, when it was first laid down. The Moors are also stated to be watching the coast, in order to resist the laying of the shore end of the cable near Tangier. The Spanish papers say that the Sultan is encouraged in his attitude towards English interests by several foreign representatives at Tangier. Finally, it is announced to-day that the British Legation has sent to the Sultan at Fez a note demanding a decision about the cable in ten days, and in this step the British Legation is backed by the presence of the fleet at Tangier.

Telephonic Communication in Paris.—The Municipal Council discussed at a recent meeting various proposals for improving telephone communication in Paris. The concession of the present company lapses on September 8th, and whether it is renewed or not the rates will be lowered and better communication secured. At present the subscription in Paris is about £24 a year. The complaints about the service in Paris have at length had some effect, the company having spent over £8,000 last month on improvements, on the chance of obtaining the renewal of its concession. Among the most ingenious proposals is that of M. Leon Donnat, a municipal councillor and leading economist, who would give the lease of the telephone system to the subscribers themselves, incorporated as a co-operative society. The rate would be reduced to £16 a year at the utmost, and in addition to this subscribers would benefit as part proprietors, while the city would probably gain by the increased exchanges.

Chelmsford.—A special meeting of the Chelmsford Town Council was held on Wednesday evening last week to consider the future lighting of the borough. Four tenders for the lighting of the town had been sent in to the lighting committee. Crompton and Co. (Limited) offered to supply 20 arc lamps, 72 incandescent lamps, and 38 oil lamps, for five years at the rate of £700 per annum. The committee recommended the council to accept Messrs. Crompton and Co.'s tender, provided that the

Digitized by Google

term for which the firm retained the right of private lighting be reduced to five years from the expiration of the contract, and subject to the details of the contract being approved by the lighting committee. Several members having shares in the Gas Company wishing to speak, the Town Clerk said he had consulted counsel on the subject, who was of opinion that any shareholders in a gas company might lawfully vote either for or against the adoption of the report and might take part in the discussion, as they had not a pecuniary interest in the matter within the Municipal Corporations' Act, 1882. After a long discussion an amendment in favour of adjournment was put and carried by a majority of one vote. It was subsequently decided to call a meeting of burgesses to consider the question, and the committee was requested to inspect the proposed position of each lamp and to report again.

The Submarine Company's Cable.—The *Central News* states that the representatives of the French and Belgian Telegraphs Department who were deputed by their respective Governments to discuss with the English officials the terms upon which the submarine cables between England and those countries should be taken over, have arrived at an agreement as to the price which shall be offered for the cables and plant. This was promptly communicated to the British Treasury, where the agreement arrived at was definitely approved, and an offer was immediately afterwards made to the Submarine Telegraph Company on behalf of the countries interested. The price which the three countries have agreed to pay is not so large as the directors of the Submarine Telegraph Company expected, but, on the other hand, it is far from being a confiscation price, which many of the shareholders anticipated. The amount will be announced in Parliament within a few days, immediately after the French and Belgian Governments have ratified the decision arrived at by their representatives. There is now not the slightest doubt that this will be done, and that the General Post Office will be in a position to take over the working of the submarine cables on the 1st of April. The officials of the English Post Office are to be congratulated upon the skill which they have displayed in bringing this most difficult business to a successful issue.

Influence of State of Aggregation on Electrical Resistance.—It was pointed out long ago by Clausius that according to the results of Arndtsen's researches on the electrical resistance of metals, the resistance of a simple metal in the solid state is directly proportional to the absolute temperature. This was subsequently confirmed by Werner Siemens, with the limitation that it does not hold good for temperatures near the melting point of the metal. Grunmach, in a recent number of *Wiedemann's Annalen*, describes some experiments from which it appears that the variation in the resistance of pure mercury does not obey this law even at temperatures much below the melting point. He finds that the temperature coefficient between 40 and 90 diminishes steadily with the temperature, as shown by the accompanying table :—

Temperature.	Temperature coefficient.
−40° to −50°	0·00226
−50° ,, −60°	0·00134
−60° ,, −70°	0·00111
−70° ,, −80°	0·00078
−80° ,, −90°	0·00037

For fluid mercury he obtains the temperature coefficient 0·00086, which is in fair agreement with Werner Siemens's value 0·00095, and the value 0·000882 obtained by Mascart, Neville and Benoît. According to Grunmach, the resistance during liquefaction only increases to about 1·5 times its original value, a much smaller increase than Cailletet and Bouty and C. L. Weber have given as the result of their investigations.

Electric Lighthouses.—Last week's Friday evening discourse at the Royal Institution was given by Sir James N. Douglas, on "Beacon Lights and Fog Signals." After tracing the history of the subject from the earliest times, the lecturer said that it was in 1858 the Trinity House first consulted Faraday on the use of the magneto-electric light. Experiments were made at the Nore, and he reported that it not only fulfilled all the requirements of an illuminant but gave prospects of development the limits of which it was hardly possible to foresee. These prophetic words had been verified. He (Sir James) had devised fluted carbons, with which it was possible to obtain a light of 150,000,000 candle-power. This was 400 times greater than could be obtained from any flame illuminant. It was far too dazzling to be used at its full power in clear weather, while, like all other lights, it was practically useless in fogs. There were intermediate atmospheric states, however, in which it was of the highest value. We are gradually coming, said Sir James, to recognise that, while electricity has undoubted superiority for salient headlands and rocks at a distance from the coast, oil or gas lights are more suited for narrow navigations. With the increase of commerce and the rapid additions to lighthouses plain fixed lights are of little use. There are the alternatives of coloured lights and intermittent lights, and it is found an occulting light has advantages over a revolving. Sir W. Thomson had suggested flashings on the dot and dash system. This might be by long and short duration lights, or red and white. For fog signals the detonation of packets of dynamite by electric currents at intervals, and automatically controlled, is the latest development. But fog, unless uniform, is an impediment to sound as well as light. Fog penetration is the problem now awaiting solution.

Electrical Energy and Solar Radiation.—Prof. I. Thornton Osmond describes in the New York *Electrical Engineer* some experiments which he has recently carried out in order to test the possibility of converting solar radiation directly into electric energy. The following is the most interesting portion of the Paper :—

I constructed a polariser of a bundle of thin sheets of glass, set in a tube at an angle of 35deg. 25min. with the axis, giving a transmitted polarised beam about five centimetres in diameter. The tube was rotated by a belt from a wheel, a beam of sunlight being sent through it from a rude heliostat.

Three coils, from 18 to 63 cm. long, with different amounts of wire, and of different internal diameter, were fitted with soft iron tubular cores, with glass plates covering the ends. These were for holding vacuum, air, liquids, &c., to be traversed by the beam, whose plane of polarisation was being rotated by the polariser.

The following are some of my series of experiments :—

(*a*) Try whether an astatic needle, silk fibre suspension, placed axially in the rotating beam, is deflected ; the same, placed at right angles to the beam.

(*b*) Try, with astatic galvanometer, cutting the rotating beam variously by a loop of wire connected to galvanometer.

(*c*) Try several metres of wire lying in (along) the rotating beam, with the ends connected through the astatic galvanometer.

(*d*) Try several metres of wire, as in (*c*), but with ends attached to quadrant electrometer.

(*e*) As (*c*) and (*d*), but using an electro-dynamometer to see whether an alternating current is produced.

(*f*, *g*, and *h*) Try passing the rotating beam through the different coils, with air, water, carbon disulphide, &c., and using galvanometer, electrometer, and electro-dynamometer.

(*i*, *j*, and *k*) Try the above with arrangement for alternately admitting and cutting off the beam, either rotating or at rest.

l, *m*, *n*, and some other experiments, I will not at present describe.

(*q*, *r*, *s*) Try a coil of wire wound longitudinally on a bar of iron, 2·2 m. long, 2·5 cm. square, with astatic galvanometer, quadrant electrometer, and dynamometer.

(*t*, *u*, *v*) Try a coil of wire wound longitudinally on a wooden bar, 2·5 m. long and inserted in an iron water pipe, with astatic galvanometer, quadrant electrometer, and dynamometer.

These experiments were made in the second story of a five-story building (above basement) used for dwelling houses, dormitories and general college purposes. The apparatus, except the astatic galvanometer and quadrant electrometer, was very rude. The polariser is but partial, the means of rotation very inadequate, and the continual jarring of the building renders certainty as to small action of galvanometers, &c., impossible.

The result is (1), my work proves that there is no opto-magnetic or opto-electric action of sufficient magnitude to be certainly discoverable, with such apparatus and under such conditions as I used, by methods (*a*) to (*k*) inclusive. (2) It is far from disproving such action.

In fact, I believe in two or three of the experiments there was indication of slight electric action.

I hope to have within a year better conditions for work in the physics building (Pennsylvania State College), now under roof, to reconstruct some of my apparatus with greater efficiency, to add some, and with improved conditions and means to retry some of these experiments more decisively, and to continue the research by other experiments.

NOTES ON ELECTRO-MAGNETIC INDUCTION.

BY DR. J. A. FLEMING, M.A.

(Continued from page 504.)

The theory must, however, be taken for no more than it is worth, viz., an attempt to construct a mechanical system which shall act in the manner in which we find electro-magnetic fields and circuits do act. The true mechanism *may* be very different; the one described has at least the utility that it shows a way in which the observed effects might be produced. The various dynamical elements in the supposed mechanism have their equivalents in the recognised electrical and electro-magnetic qualities. The angular velocity of the cells or vortices around their axes represents the intensity of the magnetic force, or the strength of the magnetic field. The angular momentum of the vortices represents the magnetic induction, and hence the mass of each cell, or the *density* of the medium, is the analogue of the magnetic permeability. This is greater in paramagnetic substances than in air or vacuum, and greatest of all in iron; in fact, so exceptional is it in iron that Maxwell supposed the particles of the iron themselves to take part in the vortex action. Hence, the energy of a magnetic field is greater if that field contain iron, and accordingly the presence of iron in a core immensely increases the vortex energy for a given vortex velocity, that is, it increases the inductance of the circuit. The energy associated with any revolving cell or vortex is proportional to the product of its velocity and momentum, or the product of the magnetic force, and the magnetic induction estimated in the same direction is a measure of the energy per unit of volume existing in that portion of the field. The "nnmber of lines of force" passing through any circuit is on this theory to be identified with the whole momentum of the molecular vortices linked with that circuit. If any circuit is traversed by lines of force or linked with lines of molecular vortices, and the cause creating this field is removed, say, by withdrawing the magnet or repressing the electric current creating it, the vortices give up their energy gradually to this secondary circuit, and it appears there as energy of motion of the electric particles or as electric current. When one system of bodies in motion sets another set in motion by mutual action and reaction, and there is no loss of energy by anything like friction or imperfect elasticity, then the momentum gained by one must be equal to that lost by the other, and the rate of gain of momentum of the one system is at any instant equal to the rate of loss of momentum by the other. Hence, if the vortices lose momentum their rate of loss of momentum—that is, the rate of withdrawal of lines of induction from the circuit must be equal to the rate of gain of momentum of, or to the force acting on, the electric particles which are absorbing the momentum. Hence we see that the impressed electromotive force in the circuit must be equal to the rate of withdrawal of lines of induction, and the theory conducts us to Faraday's law of induction as a necessary dynamical consequence of our fundamental assumption. Maxwell has extended the theory of molecular vortices to the explanation of electrostatic phenomena, with which we are not, however, here directly concerned. We have seen that the theory is capable of affording an explanation on mechanical principles of self-induction, mutual induction, and the law of electro-magnetic induction. In order to complete the theory as far as regards the phenomena of magnetism, it is necessary to suppose that the particles of magnetisable metals, such as iron, are set in rotation by the molecular vortices which traverse them, and that an increase of speed of these vortices does not increase proportionally the rotation of the iron molecules. These last behave like wheels slung loosely on a shaft between which shaft and the wheel there is friction decreasing as the speed of rotation of the shaft increases. If, then, the wheel experiences a constant frictional resistance from external causes, indefinite increase of speed of the shaft would accelerate the wheel's rotational velocity up to a certain point, and the wheel would then cease to rotate. This supposition would enable us to make our theory agree with the fact that increase of magnetic force does not increase indefinitely the magnetic induction through iron, but brings it up to a point at which, approximately speaking, the induction remains stationary. To sum up, we may say that the hypothesis of molecular vortices is an endeavour to imagine a mechanism capable of accounting for electro-magnetic induction on dynamical principles, and on the assumption that the energy of a magnetic field is energy stored up in a medium in virtue of a particular kind of rotation of its parts.

This medium consists of portions capable of elastic displacement when we consider parts of it lying in dielectrics or capable of progressive movement when in conductors, and these portions constitute what we call electricity. Other portions are capable of rotation round closed axes of rotation, and these constitute what we call "lines of force." The medium possesses, therefore, an elastic resilience, and the reciprocal of this quality, or its freedom of yielding to electromotive force, is recognised as the *specific inductive capacity*. The medium possesses also density, and we call this its magnetic permeability, or magnetic inductance. The mass of unit of length of the vortices is equal for all vortices, whether in vacuum, air, or non-magnetic bodies, but in iron the vortices are *loaded* by the adhesion to them of the molecules of the metal, and the density is increased, and hence the permeability; but for very great angular velocities—that is for great magnetic forces—the adhesion of the molecules and vortices must be supposed to cease, and the permeability approximates to unity. The magnetic force at any point in a field is the angular velocity of the vortex motion at that point, and the magnetic induction is the angular momentum. Magnetic attraction and repulsion is due to the tension set up along a vortex line by the polar contraction and equatorial expansion of the vortex cells. At places where there is magnetic polarity or free magnetism there is a discontinuity in the angular velocity of the vortices within and without the iron. Self-induction is the result of the *inertia* of the molecular vortices, whereby motion set up in them cannot be generated or checked instantaneously. Mutual induction or the production of induction currents is due to the fact that differences in the angular velocity of adjacent vortex filaments or cells causes a displacement of the electric particles or idle wheels. Finally, electromotive force is the force causing displacement of the electric particles, and electric currents consist in continuous or periodic movements of these electric particles. Electric currents always produce magnetic fields, because there is nothing of the nature of *slip* between the particles and cells, and, therefore, any progressive movement of the first sets up rotation in the second, and conversely differential rotations or spins of the cells or vortices sets up displacement of the electric particles, causing either electric strain in a dielectric or electric current in a conductor.

3. *Comparison of Theory and Experiment.*—The test of any physical theory is its power to predict new phenomena, or experimental results. The theory of molecular vortices leads to the conclusion that electro-magnetic induction must be propagated through the medium with a finite velocity, and that in dielectrics of unit permeability the velocity of propagation is inversely as the square root of the specific inductive capacity. In the dynamical theory of light it is shown that the ratio of the velocity of light in vacuo to its velocity in any given transparent medium is a constant quantity for each definite wave length, and is called the *index of refraction* of that body for that wave length denoted in physical optics by the symbol μ. Hence, the velocity of light of definite wave length is inversely as the refractive index for that wave length. The refractive index for very long wave lengths can be calculated from observed values of μ for definite rays, and hence numbers obtained representing the relative velocity of light in various transparent bodies. The values of the *dielectric constants*, or reciprocal of the electric elasticities, of various transparent and semi-transparent bodies have also been determined, and it has been found that for a large group of bodies there is a tolerably close agreement between the values of the square root of the dielectric constant and the index of refraction $\mu\infty$ for very long waves, as shown by the selection from the results of some experimental determinations given in Table A.

For some other dielectrics, such as glass and the vegetable and animal oils, the agreement is not by any means so close, but for gases as determined by Boltzmann (*Pogg. Ann.* CLI., 1875, p. 403), there is a fair coincidence. (See Table B.)

The gases are taken at 0° C and 760 millimeters pressure. Accordingly, we can say that for a large group of dielectrics, of which the magnetic permeability is unity, and hence the velocity of propagation of an electro-magnetic impulse proportional to the square root of the electric elasticity or to the reciprocal of the square root of the dielectric constant, we do find a fair agreement between these numbers and the numbers representing the refractive indices or the relative velocities of propagation of very long waves or disturbances in the ethereal medium postulated to account for the phenomena of light. The imperfect agreement between the values of refractive index for long wave lengths and the square foot of the dielectric constant for some other bodies shows that the theory is only approximately in agreement with fact, and that the results obtained by the methods adopted for determining the dielectric constant are perhaps impure, and do not give the true value of the electric elasticity. When we consider that the displacements which constitute the light wave motion of the luminiferous ether are changed some billions of times per second, it is seen to be highly probable that measurements of the specific inductive capacity in which the electric stresses are only reversed tens or hundreds of times in a second may be rendered impure or mixed owing to the presence of effects due to an imperfect electric elasticity introduced by the superposition of electric conduction or of electrolytic transport upon the true or elastic displacement effect. In fact those bodies, such as glass and the vegetable oils, which exhibit the greatest discrepancy are those in which the chemical composition indicates a possibility of electrolysis. There may be an electric displacement in such electrolysable bodies over and above the true electrostatic displacement which is engendered by a molecular change in the body, which change results in actual decomposition when the electric force reaches a certain limit. Put broadly, it may amount to this, that the true electric displacement is a displacement of electricity within the molecule, but that in electrolysable bodies electric stress sets up a strain of the molecule itself which, within certain limits, is an elastic strain, and disappears with the removal of the stress, but that beyond these limits molecular disruption takes place. In these cases the displacement measured in taking the specific inductive capacity is the true or dielectric displacement *plus* a displacement due to strain of the molecule, and the result would be to make K appear too great, and, in fact, for glass and certain oils the values in Table C have been obtained, which in all cases are such that $\sqrt{K}$ exceeds the value of $\mu\infty$ or the refractive index for very long waves of light.*

(*To be continued.*)

THE RESISTANCE OF ELECTROLYTES TO THE PASSAGE OF VERY RAPIDLY ALTERNATING CURRENTS.†

BY PROF. J. J. THOMSON, M.A., F.R.S., CAVENDISH PROFESSOR OF EXPERIMENTAL PHYSICS, CAMBRIDGE.

The electromagnetic effect of the currents induced in a conducting plate by alternations in a primary electromagnetic system in its neighbourhood, is, at a point on the side of the plate opposite to the primary system, in the contrary direction to the electromagnetic effect of the primary. Such a plate, therefore, tends to shield off from a secondary system the induction due to the primary, the diminution it produces in the current induced in the secondary depending upon the conductivity and thickness of the plate and the rate of reversal of the primary current. If the rate of reversal is infinitely rapid, a thin plate of very badly conducting substance will be sufficient to screen off from the secondary circuit all the induction arising from the primary, while if the rate is very slow, a thick plate of the best conducting metal will hardly be sufficient to do this. When the current in the primary is reversed a few hundred times per second, a metal plate of very moderate thickness will completely shield off all induction. If the thickness of the plate exceeds this limit, the currents induced in the layers next the primary will shield off all electromotive force from those layers which are more remote, so that in these layers no currents will be formed; the induced currents will thus be confined to the skin of the conductor, the thickness of the skin varying inversely as the conductivity of the plate and the rate of reversal of the current.

In Hughes' induction balance this screening effect of metal plates is made use of to compare the resistances of two metals, but with that apparatus it is hardly possible to make the alternations sufficiently rapid to produce appreciable effects with substances which conduct so badly as electrolytes; we can, however, by employing the vibrations of electrical systems such as those used by Hertz in his recent experiments on the rate of propagation of electrodynamic, action get oscillations sufficiently rapid to make the shielding effect of moderately thin plates of electrolytes quite appreciable. . . . .

The general mathematical theory is then developed, and it is shown that if with the same rate of reversal two different plates produce the same effect upon the induced current, their thicknesses must be proportional to their specific resistances, or, in other words, the resistance of slabs of the same area to currents parallel to their bounding surfaces must be the same. . . . The rapidly alternating-currents, which in the experiments were screened by the plates, were those resulting from the electrical vibrations which are set up when the electrical equilibrium of a system is disturbed. . . . The rate of propagation of a disturbance through a conductor is only equal to that of the electrodynamic action through a dielectric under certain ascertained mathematical relations, and though this will be so for the rapid vibrations we are dealing with when the conductor is metallic, it would not be so if the conductor were a dilute electrolyte or a rarefied gas. In this case the rate of propagation of the disturbance through the conductor would not be the same as that through the dielectric. In this case the action propagated along the conductor and that propagated through the dielectric would, when they met, interfere and set up standing vibrations, so that along the conductor there would be a series of stationary nodes at which the current vanished—in other words, the current along the conductor would be striated. In the discharge of electricity through rarefied gases we have the current passing through a conductor of high resistance, and it seems possible that the striations which are observed in the case may be due to the interference of the disturb-

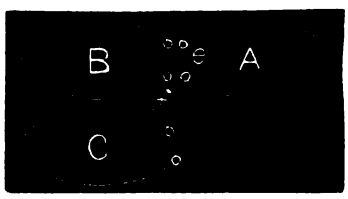
Digitized by Google

ance propagated through the conducting gas and that passing through the dielectric. The widening of the striæ on rarefaction, and on increasing the diameter of the discharge tube, are consistent with this view.

The resistances of the electrolytes to the very rapidly alternating-currents were compared in the following way :—



A, B, C are three coils, two of which (B and C) are approximately of the same dimensions, and are nearly but not quite closed. Spherical balls are fastened to the ends of these coils. The two balls of the coil C are supported in an ebonite frame provided with an ebonite screw, by means of which the two balls can be brought very near together and kept so as long as is necessary.

The coils B and C are placed on shelves of glass coated with shellac. The shelves are supported on a framework with supports at different levels, as in an ordinary book-case, so as to enable the distance between the primary and secondary coils B and C to be altered if necessary. The coil A is connected to an induction coil which, when in good order, will give sparks five or six inches long. The coil is worked by a slow mercury break, the speed of which can be regulated by altering the inclination of the arms of a fan whose motion resists that of the break : in the actual experiments the circuit was broken every few seconds. When the coil works sparks pass between the points *e* and *f*, electrical vibrations are started in the coil B ; in other words, there are alternating currents in B whose period is that of its electrical vibration, and given by equation (18). The currents in B will induce currents in C, and these latter will be rendered evident by the production of a minute spark between the two balls at its extremities. These sparks, though small, are so bright that they can be readily observed without darkening the room.

The production of sparks in the secondary circuit is much affected by what are, apparently, slight alterations in the conditions of the primary. Thus, for example, it is very much facilitated by placing the balls of a pair of discharging tongs between *e* and *f*, and allowing the spark to jump from *e* to the discharging tongs, and then from the discharging tongs to *f*. This change did not seem to be due to the resonance between the coils B and C being improved by the presence of the tongs, for unless they were placed in the way of the spark they produced no effect ; again, it was not altogether due to an increase in the quality of electricity which passed from A to B at each discharge, as this was measured by placing a specially insulated galvanometer in the circuit, and it was sometimes found that the quantity of electricity which passed when the tongs were not interposed, and when no spark was produced in the secondary circuit, was greater than the amount which passed when the tongs were interposed and when sparks were produced. The character of the spark which passes between A and B has also great influence—the best sparks are those which are perfectly straight, and accompanied by a sharp snap ; zigzag sparks in the primary very rarely produce any sparks in the secondary.

A conducting plate placed between B and C ought, as we have seen, to diminish the induction between them, and therefore the electromotive force in the current C, and since the diminution in the induction increases with the rapidity with which the current in the primary is reversed, it ought in this case to be very marked. This was found to be the case ; thin sheet metal and tin-foil when placed between the coils were found to completely stop the sparks in C. I then coated a plate of glass, which of itself had no effect upon the sparks, with a film of Dutch metal about $\frac{1}{1700}$ of a centimetre in thickness, and found that it completely stopped the sparks, and I have not been able to get a film of metal thin enough to allow sufficient induction to pass through to produce sparks in the secondary. . . .

A thick plate of ebonite was next placed between the coils, but did not produce any appreciable diminution in the sparks in the secondary ; thus ebonite, though opaque to the vibrations as rapid as those of light, still allows vibrations of which 10^8 take place in a second to pass through without interruption.

The effect of interposing a film of electrolyte was next tried. A large square glass trough was placed between the coils B and C, and carefully levelled, the electrolyte was then poured in ; when only a very small quantity of electrolyte was in the trough the sparks still passed, but they got feebler and feebler as the quantity of electrolyte in the trough increased, until finally, when the electrolyte was dilute sulphuric acid, they ceased altogether when the depth of the electrolyte in the trough amounted to three or four millimetres. The criterion adopted for the disappearance of the sparks was to allow 60 sparks to pass into the primary, stopping and starting the coils several times ; if, during this time, no sparks passed in the secondary, the sparks were considered stopped. A variation of 5 per cent. in the quantity of electrolyte present would cause the system to pass this point one way or another in a marked way.

The balls at the extremity of the secondary were adjusted so that sparks passed freely before the electrolyte was put in, after each experiment the electrolyte was removed, and care was taken to ascertain that sparks still passed as freely as before, so as to guard against any accidental disarrangement of the secondary during the experiment.

Three sets of coils were used which we shall describe by I., II., III. Set I. consisted of two circular brass coils, 140·8c. in circumference. The diameter of the brass rod of which they were made was about 0·6c. ; the balls at the extremities were 2c. in diameter. The time of vibration of this coil, calculated by equation (18), is about 10^{-8} seconds.

Set II. consisted of two circular copper coils 81·2c. in circumference, the rod of which they were made being about 0·5c. in diameter ; the balls at the extremities were 1c. in diameter. The time of vibration is about 5×10^{-9} seconds. With these small coils the balls of the secondary had to be exceedingly close together in order to get sparks, but when the micrometer screw was properly adjusted the sparks were very bright and the indications quite definite. The coils were about 9c. apart.

Set III. consisted of two rectangular coils made of sheet lead, one side was 30c., the other 40c., the breadth of the sides was 5c., and the diameter of the balls at the extremity 2c. The distance between the coils was 15c. The time of vibration about 10^{-8} seconds.

The electrolytes used were solutions of—

Sulphuric acid,	specific gravity of	solution	.....	1·175
Ammonium chloride	,,	,,	.....	1·072
Sodium ,,	,,	,,	.....	1·185
Potassium ,,	,,	,,	.....	1·155
Ammonium nitrate	,,	,,	.....	1·175
Potassium carbonate	,,	,,	.....	1·280

In the following table the relative thickness of the films of these substances required to stop the spark is given, each number being the mean of several observations. The thickness of the H_2SO_4 film was taken as unity. An observation with sulphuric acid was made before and after the observation with any other electrolyte.

	H_2SO_4.	NH_4Cl	NaCl.	KCl.	NH_4NO_3.	K_2CO_3
Coil I.	1	1·45	2·4	2·5	1·6	3·1
Coil II.	1	1·5	2·5	3·3	1·9	3·1
Coil III.	1	1·63	2·75	3·2	2·0	3·3
Mean	1	1·53	2·55	3·0	1·8	3·2
Relative resistance with very slow reversal	1	1·65	3·0	3·4	1·8	2·8

The thicknesses of the films are proportional to the specific resistances, so that the numbers in the fourth line give the relative resistance of the electrolytes to currents whose directions are reversed from 10^8 to 2×10^8 times per second. In order to see whether these resistances are the same as those with an almost infinitely slower reversal, I determined the resistance of the electrolytes by using a commutator which reversed the current through the electrolyte about 120 times a second, and kept the direction of the current through the galvanometer constant. The electrodes were platinised, and no polarisation could be detected. The numbers are given in the last line of the above table, and agree sufficiently well to enable us to say that the relative resistance of electrolytes is the same when the current is reversed a hundred million times a second as for steady currents.

It was not possible to compare in this way the resistances of electrolytes and metals, as the thinnest metallic film which could be obtained was evidently much thicker than was necessary to completely stop all induction. I succeeded, however, in comparing by this method the resistances of graphite and sulphuric acid, The graphite film was prepared by placing a sheet of glass at the bottom of a trough filled with water, holding a large quantity of finely powdered graphite in suspension ; after the graphite had deposited itself uniformly on the glass plate, the water was syphoned off, and the graphite film allowed to dry gradually. When quite dry it was hard and compact, and could be rubbed down by emery to any required thickness. By diminishing the thickness of the film and adjusting the distance between the coils, a film of graphite was obtained which just stopped the sparks ; a film of H_2SO_4 was then substituted for the graphite, and its thickness adjusted until it, too, just stopped the sparks. In this case the resistance of equal and similar areas of

Digitized by Google

the two films to currents parallel to their surface must be the same, the currents being reversed 10^8 times per second. I determined the resistances to steady currents parallel to the surface, and found that the resistance of the graphite film was 6·7 ohms, and that of the sulphuric acid 7·2 ohms; thus we may say that the ratio of the specific resistances of graphite and sulphuric acid is the same when the currents are steady as when they are reversed 10^8 times per second. Since the ratio of the resistances of such dissimilar things as graphite and electrolytes remains the same, we may conclude that the resistances themselves remain unaltered. The method described above for comparing the resistances of electrolytes is one that can be very easily and quickly applied, and only requires the simplest apparatus: an induction coil, or, if that is not available, an electrical machine, being all that is required. The method has the advantage of avoiding the use of electrodes, as all the circuits in the electrolyte are closed.

Since electrolytes are transparent, they must, if the electromagnetic theory of light is true, act as insulators when the currents are reversed as often as light vibrations, or about 10^{15} times per second. We have seen, however, that they conduct as well when the currents are reversed 10^8 times a second as when they are steady; thus the molecular processes which cause electrolytic conduction must occupy a time between 10^{-8} and 10^{-15} seconds.

Another point which can be settled by this method is, whether a vacuum is a conductor or an insulator. According to one view the great resistance which a highly exhausted vessel offers to the passage of electricity is due to the difficulty of getting the current from the electrode into the rarefied gas. When once the current has got there there is, according to this theory, no further resistance to its passage. If this theory is correct, a highly exhausted receiver placed between the primary and secondary circuits ought to stop the sparks in the latter, as since all the circuits are closed there ought to be no obstacle to the passage of the induced currents. In order to test this I took a box, 50c. by 50c. by 4c., the top and bottom of which were sheets of plate-glass fitting into wooden sides; the sheets of glass were also supported by five ebonite pillars placed at equal intervals over their surface. The box was repeatedly dipped into a bath filled with melted paraffin until it was surrounded by a coating of paraffin about 2c. thick. The paraffin was then smoothed over with a hot soldering iron, and then covered with a layer of shellac varnish. The box was then exhausted by a mercury pump, and it was found that the pressure could be reduced to about 1mm. of mercury, but no further. When this vacuum was placed between the primary and secondary coils it did not produce the slightest effect upon the sparks, so that its conductivity must be very small indeed compared with that of the electrolytes used in the preceding experiments. I am having an earthenware vessel made with which I hope to repeat the experiment at much higher exhaustions.

I also tried whether the conductivity of the electrolyte was altered by sending a current through it; for this purpose a layer of sulphuric acid was placed between the primary and secondary coils of such thickness that it almost but not quite stopped the sparks in the latter; a current of about two amperes, which was reversed about 500 times a second, was then sent through the sulphuric acid, but the passage of the current did not seem to produce any effect whatever upon the sparks in the secondary. I conclude, therefore, that the resistance of an electrolyte is not affected by the passage of a current.

I wish to express my thanks to my assistant, Mr. E. Everett, for the zeal and skill he has displayed in these experiments.

[*Note added February* 15, 1889.—I have recently tried the effect of a very high vacuum in stopping the sparks. The primary circuit consisted of two straight wires with spheres fastened to one end of each; these wires were connected with the poles of an induction coil, and the sparks passed between the spheres. The secondary consisted of two similar wires, with smaller balls at the ends, the distance between the balls being very small. The length of the wires of the secondary was altered until it was in resonance with the primary. The secondary was placed in a hollow cylinder formed of two coaxial glass tubes, sealed on to a mercury pump, by means of which a very high vacuum was obtained in the space between them, which surrounded the secondary. This vacuum, however, did not produce the slightest effect on the sparks.]

REVIEWS.

Projet d'Utilisation de la Puissance d'une Chute d'Eau pour l'Eclairage Electrique d'une Ville. By L. Vigreux, Ingénieur Civil. Chevalier de la Légion d'Honneur, &c. (Paris: Bernard et Cie., 1889.)

In the neighbourhood of a town of 20,000 inhabitants there is a waterfall some 60 feet in height; it is proposed to utilise the energy of the fall for lighting the streets by electricity. Such is the problem elaborately discussed by M. Vigreux in the work before us. The volume is accompanied by a separate portfolio containing 15 sheets of drawings, each 24in. by 20in.

For a monograph of this nature to be of any real use there would appear to be just one necessary and sufficient condition—it must be the work of a thoroughly practical man, and in that case it will also be the outcome of practical experience. Now, if we may judge from the volume before us, the author, although he is undoubtedly a distinguished Professor of Mechanics, has never had the opportunity of carrying out a scheme such as he here unfolds. One reason we have for saying this is that in any actual case the element of cost would undoubtedly enter into the question. But except for the elaborate pretence of working out the application of Thomson's law the designs are laid before us "utterly regardless of expense." M. Vigreux proposes to connect his 340 arc lamps *in parallel* on four circuits. He has novel and original (and very expensive) ideas for maintaining constancy of potential, and he seems to be unaware that arc lamps joined in parallel require a supplementary resistance in each branch. This is probably enough to convince the English reader that the work is lacking in the only *raison d'être* which we could imagine it to possess; but we wish to pursue the indictment somewhat further.

To say that no opportunity for mathematical display is ever omitted is merely to say that it is thoroughly French. This we could the more easily forgive because equations can so easily be skipped; but we find it more difficult to pardon a writer, who is presumably addressing a technical audience, for insisting on the most minute and elaborate definition of every single technical term made use of. Even in France we should suppose that nobody would come to a book like this to learn for the first time what an incandescent lamp is like, or that a dynamo is a machine for the conversion of mechanical into electrical energy. If it should appear that in making these strictures we are only slaying the already slain, we must plead that these are vices which, to a greater or less extent, run through the whole of French and German technical literature, and that so noteworthy an example, by so distinguished an author, affords an excellent opportunity for giving vent to one's feelings of exasperation which have been long and steadily accumulating. The continental writer on electrotechnics usually reminds us of the historian who, in his seventh chapter, arrived at the epoch of the creation. In the book before us, the opening sentences tell us that "all bodies, solid, liquid, or gaseous, are supposed to be constituted by an assemblage of very small elements of material points of finite mass," &c. After this we have page after page devoted to the equations of motion, to the theorem of Greene, and to definitions of mechanical and electrical units. It seems strange on turning the leaf to be confronted by a long list of streets (the author has evidently selected some existing town) with their lengths and widths minutely tabulated. But after this practical interlude we are again plunged into a pedantic disquisition on the distribution of light—a subject, by the bye, on which the author is much better informed than on his subject proper—the distribution of electricity.

The best part of the book is that devoted to the description of the dynamos—which, it appears, the engineer is expected to build for himself. Excellent working drawings of an Oerliken dynamo are given, and the calculations, although they begin absurdly enough, after a certain point become quite sane and intelligible. It is pretty clear that the author has obtained some information from the Oerliken Works which he first tried to improve on, and afterwards incorporated *en bloc*.

In conclusion, we can only express our unbounded astonishment that so elaborate and expensive a publication should fall so grievously short of its ostensible aim. The volume reads more like a weak but ambitious prize essay than an engineering treatise; and if this was really its genesis it seems a pity that the prize was ever awarded.

"Supplement to Carpmael's Patent Laws of the World." (London: William Clowes and Sons. 1888.)

The preface states that this volume "has, by the wish of the Institute of Patent Agents, been prepared by a Committee of Fellows of the Institute with the object of bringing down to the

Digitized by Google

latest date precise information as to the various legal enactments in foreign countries and the colonies." The work consists in textative reproductions of the patent laws of 23 countries, and is without doubt a most valuable and labour-saving addition to the original work of Messrs. A. and E. Carpmael, published in 1885, and well known to all patent agents. The present volume, of course, appeals only to those actively engaged in the profession, or whose business it may be to be informed on the subject; to others it will naturally be without interest.

The preface states that "Mr. Edward Carpmael, as one of the Committee of the Institute of Patent Agents, has devoted much time and labour to the preparation of the work, and to his energy and ability the issue of the present volume is largely due." There can be no doubt as to the time and labour, and from the source and auspices of the work it should be accurate.

Glimpses of Feverland; or a Cruise in West African Waters. By Archer P. Crouch, B.A. (London: Sampson Low, Marston, Searle and Rivington, 1889.)

The author of "On a Surf-bound Coast" is sure to meet with a warm welcome from every reader of his earlier volume. The story of the laying of the cable from St. Paul de Loanda to St. Thome is interesting enough in itself, but this is subordinated to the description of the writer's personal adventures on the way from Sierra Leone in a coasting steamer, and on various trips to and fro amongst the ports and islands of the Gulf of Guinea. The easy, unaffected style of the narrative, the continual flow of incident, sometimes trivial but always entertaining, and the admirably-drawn pictures of life and scenery in a region little known, contribute to make this a really delightful book. Once begun it will be read from end to end, and finally laid down with something like regret.

THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 9th inst., Prof. Oliver J. Lodge read a Paper on

"The Rotation of the Plane of Polarisation of Light by the Discharge of a Leyden Jar."

The author pointed out that electrical effects depending on the total amount of a current and not upon its duration, such as induction currents, magnetisation, and rotation of the plane of polarisation, can be well produced by means of the Leyden jar discharge.

When a beam of polarised light is sent through a piece of heavy glass or a tube containing bisulphide of carbon, and the analyser is so adjusted as to give the maximum extinction, a sudden appearance of light is observed when a Leyden battery is discharged through a coil surrounding the glass or tube.

The oscillatory nature of the discharge and the consequent oscillatory restoration of light in the dark field is conclusively demonstrated by the fact that a small rotation of the analyser in either direction from the position of maximum extinction has the same effect on the result, and also by the fact that the sensitive tint of a bi-quartz is unaffected by the discharge.

The experiment seems to show that the effect is practically instantaneous, a conclusion which is at variance with the conclusion deduced by Villari ("Rendiconto del Istituto Lombardi," Ser. II., Vol. III., translated in *Poggendorff's Annalen*, Vol. CXLIX.) from observations on a drum of heavy glass rapidly whirled between the poles of a magnet. Villari found that the rotation of the plane of polarisation diminished as the speed increased, and almost entirely disappeared when a speed of about 180 revolutions a second was attained, from which he concluded that a time between $\frac{1}{800}$ and $\frac{1}{400}$ of a second was required to produce the effect.

In 1882 Messrs. Bichat and Blondlot had made a series of beautiful experiments (*Comptes Rendus*, Vol. XCIV), from which they concluded that if time were required to produce the effect it could not exceed $\frac{1}{30000}$ of a second. Professor Lodge observed that the investigation contained in his Paper consisted practically in a repetition of their results with the working out of the theory.

In order to determine whether any perceptible time was required for the effect, the two French physicists allowed the light traversing the tube to illumine a slit, while a second slit immediately above the first was illuminated by the spark of the discharge causing the rotation. The light passing through both slits was spread out into discontinuous bands by means of a revolving mirror, and the serrations in the two bands were found to agree exactly, as far as could be observed, showing that no perceptible time was required for the production of the effect. They also mentioned an experiment made by Messrs. Curie and Ledeboer, in which no diminution was observed in the effect in the case of a disc of glass spun, like a Foucault copper disc, between the poles of a magnet. Professor Lodge finds from his own experiments that the sulphide of carbon shows the effect when the rate of alternation is as high as 70,000 in a second. The oscillatory character of the effect was then exhibited to the Society by allowing the polarised beam which had traversed the sulphide of carbon to fall upon a rotating mirror, after adjusting the analyser to give the maximum extinction possible. A faint band of light was thus obtained, which was observed to become brighter and assume a distinct beaded appearance at every discharge round the tube. When the analyser was slightly rotated in either direction every alternate bead became fainter, while the remaining ones became brighter, which distinctly demonstrated the oscillatory character of the light.

Theory of the Effect.—The current at any instant is given by the equation

$$C = \frac{V_0}{pL} e^{-mt} \sin pt \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where $$m = \frac{R}{2L} \quad \text{and} \quad m^2 + p^2 = \frac{1}{SL},$$

S being the electrostatic capacity of the circuit, L its coefficient of self-induction, R its resistance, and V_0 the initial potential difference.

Again, the magnetic potential difference between the ends of a tube of length l, containing a substance of magnetic susceptibility μ, and surrounded by a very long solenoid containing n_1 turns of iron wire per unit length and traversed by a current C, is

$$4\pi\mu \, C n_1 l.$$

Calling the Verdet constant, or the rotation per unit difference of magnetic potential, for sulphide of carbon k, the total rotation will be

$$\theta = 4\pi k n_1 l \mu C \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Let a be the total amplitude of the light falling upon the analyser, then the component transmitted when the analyser is set to extinction, supposing this to be complete, will be $a \sin\theta$, and the amount of light transmitted during a time τ for which an impression is capable of being accumulated on the retina will be $\int_0^\tau (a \sin\theta)^2 \, dt$. The amount of light passing during the same time with the analyser set to maximum brightness, supposing all the light transmitted, will be $a^2\tau$, so that

$$B = \frac{\text{apparent brightness restored by spark}}{\text{maximum possible brightness}} = \int_0^\tau \frac{a^2 \sin^2\theta \, dt}{a^2 \tau} = \frac{1}{\tau}\int_0^\infty \sin^2\theta \, dt \quad . \quad . \quad . \quad (3)$$

approximately, since τ is very great compared with the duration of the discharge. When θ is small this may be evaluated in the form

$$B = 160 k^2 n_1^2 \frac{\frac{1}{2} S V_0^2}{R\tau} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Its general value is

$$B = \frac{1}{2m\tau}\int_0^\Lambda \frac{1 - J_0(x)}{x} dx.$$

Where J_0 is the first Bessel function, and

$$A = 8\pi k n_1 \mu V_0 \sqrt{\frac{S}{L}}$$

Numerically it comes out from the equations that though the rotation must be very great, probably from 60° to 180°, the restoration of light is only some ten thousandth of what would be obtained by rotating the Nicol prism. This explains why it is easy to analyse the restored light into a beaded band, for here the effect of the separate oscillations are obtained, and these are very bright though momentary.

The formulæ show that to get large effects a large battery, charged to a high potential, should be employed, the latter, however, being limited by the condition that it must not be sufficient to endanger the coil.

They show, moreover, that the addition of self-induction is indifferent, the reason being that while it diminishes the effect of each oscillation it prolongs its duration, and has no effect on the total action; and they also show that increased resistance diminishes the effects.

Prof. Lodge thought that Villari's results might have been due to a state of strain being set up in the glass by the centrifugal force, though, in that case, a similar effect ought to have been produced in the absence of a magnetic field, which Villari says was not the case. Professor Lodge, however, pointed out that if there

Digitized by Google

were no magnetic rotation the aspect of the plane of polarisation, with respect to the direction of the stress, would remain constant, which would not be the case when there was magnetic rotation. This might possibly lead to an explanation, though he did not understand how the change of aspect could diminish the rotation instead of giving rise to elliptic polarisation.

DISCUSSION.

Mr. WARD said he had been experimenting in the Cavendish Laboratory on the subject of Villari's experiment. He had constructed apparatus similar to Villari's, and he found that the bi-quartz underwent changes in colour, indicating elliptic polarisation. This would make it impossible to observe a change in the plane of polarisation. Villari ought to have recognised this fact, which accounted for the extreme irregularity in the results recorded in his tables, an irregularity which he himself attributed to the difficulty of maintaining the speed of rotation constant. When a state of strain was set up in the disc there would be a rotation of the plane of polarisation, together with elliptic polarisation. In the case of an elliptically-polarised beam the effects of rotating the plane of polarisation by the action of a magnetic field was to shift the axes of the ellipse. He used a pair of crossed Nicol prisms in his experiments, and an alternating current of high frequency. He suggested that it would be desirable to use a dynamo, an alternating current of high frequency to be sent round the glass. He considered that the mathematical examination of Villari's paper showed that it was of very little value, owing to his having completely overlooked the fact that strained glass causes elliptic polarisation.

Prof. RUCKER referred to a paper by Dr. Cook "On the Existence of an Undulatory Movement Accompanying the Electric Spark,"* read before the Society on June 23rd, 1888, and to an experiment of Dr. Guthrie's which he had exhibited in connection with it at the same meeting, in which the discharge of an electric spark at one of the foci of an elliptic tray gave rise to ripple marks on the surface of the tray, which had been previously sprinkled with some powdered substance. He thought that this result, as well as the results observed by Dr. Cook, were due to air ripples produced by the electrical oscillations. The electrical vibrations in the case of the experiment with the elliptic tray would be something like a million a second, and the distances between the ripple marks were about what would be produced by the corresponding oscillatory motion excited in the air. He considered it an interesting fact that heavy glass and sulphide of carbon behaved in the same manner in Prof. Lodge's experiments, as there were differences in their behaviour as regards electrical stress.

Prof. LODGE stated that he did not assert that the actions were numerically identical, as he had not sufficient data at his command to warrant it. He had hitherto only had a small piece of glass to experiment with, and, therefore, he could only assert a general similiarity in the behaviour of the two substances. He said that Prof. Rücker's idea had occurred to Mr. Chattock, his assistant, and he had made some experiments. The ripples obtained were about a millimetre apart, and the frequency of electrical oscillations required to give air waves of this length came out to about the value anticipated theoretically.

Prof. AYRTON said that Prof. Perry and himself, in investigating the E.M.F. curve of an alternating dynamo, had employed a method for detecting oscillations too rapid for the eye to follow, which might be of use in the present investigations. To the receiving membrane of an Edison phonograph of the old type they attached a small coil which was traversed by a steady current. Near to this was placed a fixed coil carrying the alternating current. The vibrations due to the variation in the mutual attraction of the two coils were thus recorded on the tinfoil, the machine being made to rotate rapidly. If the cylinder were then made to rotate more slowly an audible note might be obtained. In their experiments they took out the receiving membrane, replacing it by a transmitter to which they had attached a magnifying spring giving one complete rotation of the pointer for an extension of $\frac{1}{100}$ of an inch, and having a mirror attached to it. The tinfoil was then turned through a measured angle and the rotation of the pointer observed, and in this manner they were able to get all the ripples on the wave.

Prof. Lodge then exhibited an experiment analogous to some of Dr. Hertz's, illustrating Electric Resonance.

The sparks from a Holtz machine were made to pass between two brass balls at a small distance apart. In front of the air space traversed by the sparks was placed a resonator which had been tuned to electric unison with the circuit of the Holtz machine. This resonator consisted of a pair of condenser plates placed at a short distance apart and nearly touching at one edge, so as to allow of a spark passing, the plates being joined by means of a gutta-percha covered wire. Sparks were then seen to pass between the condenser plates when the machine was in action. It was then shown that the insertion of additional self-induction in the resonator circuit caused a cessation of the sparks by throwing it out of unison with the exciting circuit.

A Dictionary of Electrical Terms.—We learn that "A Dictionary of Electrical Words, Terms, and Phrases," by Prof. E. J. Houston, will shortly be brought out by the *Electrical World* of New York.

* *The Electrician*, December 28th, page 224.

RELATIVE AMOUNTS OF VOLTAIC ENERGY OF DISSOLVED CHEMICAL COMPOUNDS.*

BY G. GORE, LL.D., F.R.S.

In this investigation the author has measured by the "voltaic-balance" method the amounts of relative voltaic energy or of chemical affinity for zinc, of nearly 250 aqueous solutions of chemical compounds, including those of elements with elements, elements with monobasic, bibasic, and tribasic acids, acids of all these classes with each other, elements with monobasic, bibasic, tribasic, and tetrabasic salts, monobasic, bibasic, and tribasic acids with all these classes of salts, and all these classes of salts with each other in large variety; and he offers the results as additional evidence in support of the conclusion that "*every electrolytic substance or mixture when dissolved in water unites chemically in definite proportions by weight with every other such dissolved body*, provided no separation of substance occurs;" and that "there may probably be discovered thousands of such compounds which only exist whilst in aqueous solution, and are decomposed on evaporating or crystallising their solutions" (Roy. Soc. *Proc.*, Vol. XLIV., p. 267). The results are given in the form of a volta-tension series of electrolytes.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, March 22nd.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "The Cyclical Velocity Fluctuations of Steam and other Engines." By H. B. RANSOM, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "The Science of Animal Locomotion in its Relation to Design in Art." (Illustrated by the zoopraxiscope.) By EADWEARD MUYBRIDGE.

SATURDAY, March 23rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Experimental Optics (Polarisation: Wave Theory)." By the Right Hon. Lord RAYLEIGH, M.A., F.R.S.

PHYSICAL SOCIETY.

3 p.m. "On the use of Lissajou's Figures in the Maintenance of Uniform Rotation," and "On the Direct Determination of the Vibration Period of a Reed or Tuning Fork by means of a Morse Receiver." By Prof. J. V. JONES. "On the Clark Cell as a Source of Standard Currents." By Prof. R. THRELFULL and A. POLLOCK. "On the Measurement of High Specific Resistance." By Prof. R. THRELFULL.

MONDAY, March 25th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture V., 1. "Instruments for the Measurement of Radiant Heat." By C. V. BOYS, F.R.S.

TUESDAY, March 26th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Before and After Darwin." By GEORGE JOHN ROMANES, M.A., F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. "The District Distribution of Steam in the United States." By C. E. EMERY, M.I.C.E.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. "Borneo." By ROBERT PRITCHETT.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture.—Part II. "The History of a Crime Unravelled by a Piece of Rusting Iron, a Horseshoe and a Match." By Prof. H. E. ARMSTRONG.

WEDNESDAY, March 27th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Adjourned Discussion on Prof. Kennedy's Paper, "The Objects and Methods of the Society of Arts' Motor Trials."

THURSDAY, March 28th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Houses and Their Decoration from the Classical to the Mediæval Period." By Prof. J. HENRY MIDDLETON, M.A.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. Paper not decided on.

* Abstract of a Paper read before the Royal Society, March 14, 1889.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"THE ELECTRICIAN" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"THE ELECTRICIAN" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. The DIRECTORY was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.

THE DIRECTORY for 1889 is NOW READY.

CONTENTS OF THE CURRENT NUMBER.

NOTES 555
Notes on Electro-Magnetic Induction. By Dr. J. A. Fleming, M.A. Continued. . 560
The Resistance of Electrolytes to the Passage of very Rapidly Alternating Currents. By Prof. J. J. Thomson, M.A. Illustrated 561
Reviews 563
Physical Society.—"The Rotation of the Plane of Polarisation of Light by the Discharge of a Leyden Jar." 564

"THE ELECTRICIAN" IN THE UNITED STATES.

Similarly, "THE ELECTRICIAN" can be obtained in America at the Offices of THE W. J. JOHNSTON COMPANY, LIMITED *("THE ELECTRICAL WORLD"), 168 to 177, Potter-building, New York.*

"THE ELECTRICIAN" can also be obtained from THE D. VAN NOSTRAND COMPANY, *23, Murray-street, and 27, Warren-street, New York.*

The Rate of Subscription for American Subscribers (payable in advance) is $6 per annum.

Volume XXI. of "The Electrician" is NOW READY

Price 12/6, post free 13/6.

Cases for Binding Volume XXI. are also Now Ready, Price Two Shillings, Post Free, Two Shillings and Threepence.

ELECTRIC LIGHTING IN THE METROPOLIS.

IN nearly all the Metropolitan Vestries and District Boards, as well as in half the Municipalities of the kingdom, Electric Lighting Committees are now the order of the day; and although hitherto there has been a great deal of cry and surprisingly little wool, yet the time has at length arrived when the projects for which Provisional Orders have been already applied for must be dealt with in earnest. In this matter the actual responsibility rests chiefly with the Board of Trade, and in so far as the Metropolis is concerned that responsibility is no light one. Questions of the greatest difficulty and delicacy must be dealt with, and to reconcile the competing interests of rival companies, the divergent views of multifarious local authorities, and, at the same time, to safeguard the interests of the private consumer is a task which will demand no small degree of patience and of skill for its accomplishment.

In determining to hold a public inquiry into the merits of the various schemes now in train the Board of Trade have in all probability adopted the most satisfactory course which was open to them. The inquiry will be held under the presidency of Major MARINDIN, at 8, Richmond-terrace, Whitehall, commencing at 10.30 on Wednesday, April 3rd. Ostensibly it is instituted to report upon the various applications for Provisional Orders and Licenses now before Parliament and the Board in respect to the Metropolis, and lodged under the Electric Light-

Digitized by Google

EXTRACT FROM THE "ELECTRICAL REVIEW" OF FEBRUARY 8th, 1889.

"Two years ago the Taunton Electric Light Company possessed one dynamo, now it possesses six. On Monday, at the second annual meeting of the Shareholders, a dividend of 6 per cent. was recommended, and next year it is confidently expected that this will be increased. A glance at our City columns will show that the plucky efforts of the directors have been highly successful, and everybody will bear out the assertion of Mr. Potter, that the history of this company is **UNPRECEDENTED IN THE ANNALS OF ELECTRIC LIGHTING** in England. May it go on and prosper!"

The **SYSTEM** *in use at* **TAUNTON** *is the* **"THOMSON-HOUSTON,"** *installed and started to work by LAING, WHARTON & DOWN, and now owned and worked at a good profit by the above local Lighting Company. Over 450 similar Plants are at work in other parts of the world, all successful, both from the consumers' and from the investors' point of view.*

THE ELECTRIC MOTOR AND ITS APPLICATIONS.

By T. C. MARTIN and J. WETZLER.

1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

JUST PUBLISHED. Cloth, 279 pages. 59 Illustrations. Price 10s. 6d. Post Free, 11s.

PRINCIPLES OF DYNAMO-ELECTRIC MACHINES.

PRACTICAL DIRECTIONS FOR DESIGNING AND CONSTRUCTING DYNAMOS. With an Appendix containing several articles on Allied Subjects, and a table of Equivalents of Units of Measurement. By CARL HERING.

The above work, just published, is the first American book on Dynamos, and the reputation of the author as a clear, concise writer on the subject of which it treats, is sufficient guarantee of the character of its contents. The book is copiously illustrated, printed on an extra good quality of paper, and neatly and substantially bound.

ing Acts. But as these applications have been made either with direct reference to the wishes of the respective Vestries or in opposition to them, we may take it that Major MARINDIN will have before him the subject as a whole, including, not improbably, the views of the newly-created County Council, who will have assumed the functions of the Metropolitan Board of Works, and inherited the right to be consulted in respect of the open spaces previously under the jurisdiction of that body.

The inquiry does not promise to be a very brief or a very agreeable one if, as may be surmised, the Vestries insist strongly upon their own preconceived views. In reality, the chief complications of the situation seem to be due to the over-zeal and activity of the Vestries. But besides this, the fact that for a comparatively limited area of the Metropolis already eight electric supply companies are applying for eleven Provisional Orders, covering no fewer than twenty-three "local authorities," as defined by the Act, adds considerably to the difficulties to be overcome, especially if the remaining Vestries are as self-assertive as those who have already spoken their minds on the subject. We noted at the time in our comments on the Kensington scheme that the six companies affected had shown a much too pliant temper in yielding to the suggestions of the Vestry as to the reduction of the forty-two years' interval allowed by the Act, and we have reason to believe that this opinion is shared to some extent by the Board of Trade. The Companies will now have an unlooked-for opportunity of retrieving the error then committed, and we trust that they will be wise enough to present a bold and united front to the attack which is sure to be delivered upon this point. So long as they hold to the terms granted by the Act their position is legally and logically unassailable, and to tamely yield evinces a moral cowardice, which is the more reprehensible since the consequences will inevitably be felt by Electricity Supply Companies in all parts of the country.

Another important point which the present inquiry will have to determine is the feasibility of splitting up the areas represented by the parish unit into several sections served by as many competing electric light supply companies. In Kensington—and its example has been partially followed elsewhere—the Vestry appear to have acted on the principle that, as there were so many applicants exactly so many districts should be assigned to them. In some other areas the local authority has shown a more independent desire to place them each under one single and well-appointed company; whilst others, again, prefer to allow an indiscriminate competition over the whole area, without any strictly defined topographical boundaries. To reconcile these various and conflicting propositions will be one of the chief tasks of the Board of Trade inquiry; and we need hardly say that it is one of no small magnitude and complexity. Moreover, as the various Metropolitan areas have been taken up, or, more correctly, applied for, the impracticability of the sub-division which the companies agreed to has become almost self-evident. Looking at the Map of Metropolitan Improvements issued with the private Bills this Session, it will be seen that the electric lighting areas are severally laid claim to by a number of companies varying from two to six, and with absolutely no relation whatever to the districts they may occupy in adjacent or remote quarters. Manifestly such a sub-division of their operations is the least economical that could be devised for the companies. If any one of the areas were to be exploited alone, and by way of an experimental competition between half-a-dozen of the leading supply companies, the thing might be tolerated, yet even then only as an experiment and scarcely as a serious business enterprise. But directly operations are contemplated beyond this narrow boundary the whole system assumes the character of a series of independent schemes, that company alone being in any degree fortunate which by a lucky chance happens to obtain two districts immediately adjoining although in different parishes.

At the present stage of electric lighting business it would be impossible, and even if possible undesirable, that any very large area at all resembling those supplied by the London gas corporations should be assigned to one electric supply company. A combination, resulting in a similar way, will doubtless take place in due course as it has in the case of the gas companies; but for the present it would be unwise to attempt too much; and the Board of Trade will take good care, in the interests of the public, that a judicious limitation of the several companies' operations is not overstepped. If, however, any one company is deemed capable of supplying more than one small area in different localities, that company may surely be trusted to supply any one given area of equal dimensions in one locality. We shall not be surprised, therefore, if the Board of Trade were to set aside the propositions now before it so far as the majority of the Vestries are concerned, and adopt some intelligible sub-division of its own on a more rational basis, giving to each company a certain local area for which it shall be solely responsible, though not necessarily confined to that one area. When the company is large and sufficiently equipped with capital and experience there is no reason why it may not have two or more important areas assigned to it. All that we deprecate is the excessive sub-division of small parishes and the splitting-up of the resources of the companies into a multitude of insignificant and separated undertakings.

As to the other objections raised in our former article on this subject, we need not refer to them again further than to observe that this inquiry will afford opportunity for laying them before the Board if the companies concerned think it worth their while to do so.

THE INDIAN TELEGRAPH DEPARTMENT.

(From the *Indian Engineer.*)

The annual report of the Indian Telegraph Department during 1887-88 shows that a considerable increase took place during that year in the number of miles of line open, the number of messages sent, and in the receipts. The most important event during the year was the transfer to the charge of the Director-General of the Indian Telegraph Department of the Indo-European Telegraph Department, which had hitherto been administered by a Director-in-Chief, whose headquarters were in London. This transfer took place on the 15th February, 1888. Although the total number of messages received for despatch by the Indo-European lines increased by nearly 30,000 during the year, and the total receipts by about 1½ lakhs, it is stated that the traffic between India and Europe shows no marked difference between that of the past three years, the increase being due to a greater number of messages passing between Europe and countries to the east of India, including Australia. The Teheran route was interrupted with Great Britain from the 13th to the 17th December, 1887, and from the 1st February, 1888, to the end of March, owing to the failure of the North Sea cables between Emden and Lowestoft, and owing to this cause and the delay in repairing the second interruption due to bad weather the traffic by this route shows a considerable falling off, while the Suez route proportionately gained. There seems to have been no break in the Suez route which is said to have worked admirably, and the only important interruption on the Turkish route was one between Bagdad and Mossul in April, 1887, which lasted 16 days.

With regard to telegraphic communication with other Eastern countries, communication was maintained throughout the year, without interruption, between India and The Straits, China, and Australia, though direct communication between India and China was cut off between the 30th July and the 7th August by the failure of the single cable which connects Singapore and Saigon. During this interval the China traffic from and to Europe was sent by the Great Northern Telegraph Company's line through Asiatic Russia. The Indo-Siam line is said to have proved almost valueless as a through international route from India to Saigon, and the number of messages sent was very small. The Northern route from Moulmein to Bangkôk, *via* Raheng, was almost constantly interrupted

Digitized by Google

throughout the year, and the Southern route *via* Mejetta and Kanburi was also subject to long interruptions, mostly in Siamese territory. The portions of these lines within British territory, though traversing most difficult and unhealthy forest and mountainous country, were kept in good working order. Representations regarding the state of the line in Siamese territory were made to the Siam Government, and it is hoped that some improvement will take place.

Telegraphic communication in China was considerably extended during the year. The Northern line from Shanghai *via* the provinces of Hupe and Szechuen was completed to Yunnan and three offices were opened in that province, which is partly co-terminous with the British frontier in Upper Burma. A second line from Yunnan to the coast ports, *via* the provinces of Kwangsi and Kwantung to Canton, was also under construction, and from recent official reports was expected to have been completed to Yunnan in March last, thus affording two routes from that place to the Pacific Ocean. There now remains but a short link to connect the wires of the Indian Telegraph Department and those of the Chinese Government, in the neighbourhood of Bhamo, and when this is done, it is probable that a comparatively cheap tariff for telegraphic communication between India and China will be arranged for between the Governments of the two countries. At the present time the distance between the nearest points of the Indian and Chinese systems is only about 140 miles, viz., from Bhamo to Momein, in Western Yunnan.

During the year the Island of Formosa was connected with Foochow by a submarine cable, and three offices were opened in the island; telegraphic communication was established between Malacca and the States of Selangor and Sungie Ujong, and three offices opened in each State. A cable was also laid from Gibraltar to Tangier, establishing communication with Morocco.

The total length of line open at the end of the year was 93,743 miles, representing 93,517 miles of wire and 226 miles of cable. During the year there was an increase in the total length of 6,657 miles, representing 6,627 miles of wire and 30 miles of cable. A large portion of the wire lines are worked by railway companies, there being no less than 33,043 miles of wire in connection with the various railway systems, and much of the increase in the total length of line noticed above was caused by the opening up of new lines or the extension of existing ones. In Burma the work has mainly consisted in consolidating and strengthening existing lines. Communication between Upper Burma and Assam has been established by the completion of the line from Manipur *viâ* Tammu and the Chindwin Valley. This line runs from Mandalay to Ava, where a cable crosses the Irrawadi and connects it with Sagain. From thence it is carried across country *via* Myinmu to Moniwa where it meets the Chindwin and follows the Valley up to the junction of the Yu River, after which it follows that river to Tammu. The connection of Upper Burma with India by this route has been attended with considerable difficulty, and the staff employed suffered much from hardship and exposure which brought on fever and malaria.

The result of the trial of hard drawn copper wire having been favourable, a wire of this metal was put up between Bombay and Madras, 800 miles, and between Bombay and Nagpur, 520 miles. It is in contemplation to extend this latter by wire of a similar metal, to Calcutta, as soon as the line of post along the Bengal-Nagpur Railway is completed. The results obtained on the new wire are highly satisfactory. Bombay and Madras are now able to work quadruplex without any intermediate translating station. The difficulties connected with the manipulation and erection of the "hard drawn copper wire" have in practice proved, with ordinary precautions, to be less than was anticipated. The use of this wire would have been much extended had it not been for an exceptional rise in the price of copper, which has rendered the purchase of it for the present almost prohibitive. It is, however, in contemplation to attempt its manufacture in the telegraph workshops in Calcutta, utilising old cable core and copper in stock.

Quadruplex working was introduced during the year on the line between Calcutta and Rangoon, a distance of over 1,000 miles, with Akyab as a half-way station, where the signals are automatically repeated. The introduction of the same system was also arranged for on one of the wires between Calcutta and Agra, with Allahabad as the repetition station. The number of circuits worked duplex has also increased, and there are now twenty-three main circuits, most of them of great length, worked on the quadruplex or duplex system. The suspension of a copper wire between Madras and Bombay, which was completed early in the year 1888, has very much improved quadruplex working between those cities, and the important Australian and China traffic which mainly traverses India by this route is disposed of with great ease and rapidity.

With a view to afford the Meteorological Department facilities for promptly warning the various ports of India and Burma of approaching bad weather a special class of storm signal telegrams was introduced with the approval of Government on the application of the meteorological reporter to the Government of India. A considerable number of the meteorological observers throughout India are *employés* of the Telegraph Department, and as the work of the two departments are so much connected, the arrangement is advantageous, and saves much delay in the despatch of weather telegrams.

ARC LAMPS AND THEIR MECHANISM.

BY PROF. SILVANUS P. THOMPSON, D.SC., M.I.E.E.

(Continued from page 537.)

[A.] Driving Power.

The following devices have been used:—

1. *Gravity.*—Descent by its own weight of upper carbon holder [innumerable lamps]; ditto, aided by weights specially attached [Gülcher, 1915[82]]; ditto, partially opposed by coiled spring to compensate for consumption [Siemens, 366[88]]; clockwork driven by weights [Staite, 11783[47]]; lower carbon floated upward in mercury [Tommasi, 4405[79]].

2. *Coiled Spring.*—Drives by pinion and rack, or pulley and cord [Foucault, 1848; Staite, 11449[46]]. Differential action of two coiled springs [Foucault-Duboscq lamp].

3. *Electro-magnetic Motor.*—(*a*) Suction of core by solenoid; (*b*) electric motor rotates and drives carbon rod [Bousfield, 523[79]; Breguet, &c.]; (*c*) electro-magnetic vibrator drives carbon rod [Clark-Bowman, 1182[83]; Newton, 1623[83]; Pieper, 4133[86]; Holmes, 769[86]].

4. *Hot Air.*—Heated air rising from lamp drives fan to propel carbons [Varley, 5656[81]].

[B.] Striking Mechanism.

To strike the arc requires mechanical devices; but as these are to be actuated by the current itself, it is appropriate first to consider what electric mechanism is necessary or sufficient to actuate the movement. Assuming that the carbons are initially in contact when there is no current, the current when turned on must part them; the appropriate device is therefore an electromagnet (or solenoid with its core in lieu thereof) having its coils in the main circuit of the lamp. [Foucault, 1847; Staite, 11783[47], and in the vast majority of modern lamps.] If, however, the carbons are initially apart, the lamp must itself bring them together, and the appropriate device to actuate this movement will be an electromagnet (or solenoid) connected as a shunt, and therefore having fine wire coils of high resistance. Such an arrangement will bring the carbons together by the action of the by-pass current, and as this falls almost to zero on the contact of the carbons, they will be at once parted (and the arc struck) by the opposing force: this force may be that of gravity [Lontin, 1875) or a spring [Lever, 2092[82]; Thomson-Rice]. The disadvantage of this second method is that the initial resistance of the whole series of lamps standing with their carbons parted is enormous unless there is a cut-out circuit. Another method of striking the arc is by cutting out a main-circuit electro-magnet [Crompton, 346[82]; Bright, 377[82]].

The modes of parting the carbons are various:—

1. Drawing both carbons asunder by gearing [Foucault-Duboscq lamp].

2. Drawing down the lower carbon by electro-magnet placed in base [Staite, 11783[47]; Serrin, Breguet, Sellon, Newton, Pieper, Holmes, &c.], or by electro-magnet situated at top [Crompton "E," 1881; Gramme; Silvertown Co.; Fein, 1888].

3. Lifting upper carbon rod [Roberts, 14198[52]; Slater and Watson, 212[52]; and the vast majority of modern lamps, Brush, Siemens, Crompton, Pilsen, Brockie-Pell, Thomson-Houston, &c.], or lifting upper carbon by an electro-magnet situated in the carbon rod [Abdank, 1884]; or by lifting bodily the upper carbon and the whole of the feeding train [Crompton, 346[82]; Fyfe and Main, 3821[81]; Bergot, Wood, Hochhausen, Maxim, 1649[80]; Gümpel, 253[81], &c.]; or by rocking the feeding train around a centre [Brockie, 2370[82]; De Puydt].

The mechanical devices for performing these various actions are numerous, and their action is complicated by the endeavour of many inventors to cause the same mechanism which initially strikes the arc also subserve the purpose of feeding the carbons. In some lamps, however, these functions are kept separate. An example of a lamp in which the striking and feeding mechanisms are kept separate is afforded by the Breguet lamp (Fig. 3), in which an electromagnet draws down the lower carbon holder to strike the arc, whilst the feeding is accomplished in the subsequent gradual descent of the upper carbon. In the lamps of Newton, Sellon, and Holmes, there is used the special form of short-range electro-magnet, *a* (2 in the list), having a central core and external tube of iron. There is a

Digitized by Google

very numerous class of lamps in which a clutch is caused to grip the upper carbon holder, and then to raise it so as to strike the arc; the same clutch being subsequently so operated as to permit the carbon holder—a smooth rod—to slide down by degrees as required, to feed the carbon pencil forward. Such devices are best considered under the heading of feeding mechanisms.

The adjustments of the striking mechanism may be of two kinds—(1) adjustments of range, such as limiting stops and set screws; (2) adjustments of force such as the regulable spring shown in Fig. 1 at the bottom.

The main-circuit electro-magnetics and solenoids, used for striking the arc, are wound with a wire of large enough section to carry the required current without undue heating, and are of small resistance. The weight of copper wire employed varies from one to four pounds; and the resistance varies from 0·05 to 9·2 ohms.

[C.] Feeding Mechanism.

The electric devices here differ in the case of lamps for parallel working and lamps for series working.

(1.) *For Lamps in Parallel.*—Assuming that the supply mains are kept at constant potential, then the lamp mechanism must be responsible for keeping the other factor of the electric power, namely, the current through the lamp, at a constant value. That is, say, whenever by reason of the burning away of the carbon points the arc grows long, offering more resistance, and, therefore, reducing the current below its normal value, the lamp must automatically feed the pencils forward, and so readjust the current. It is obvious that, in this case, the weakening of the current through the lamp may be caused to bring the feeding mechanism into operation by the use of an electromagnet (or solenoid) in the main

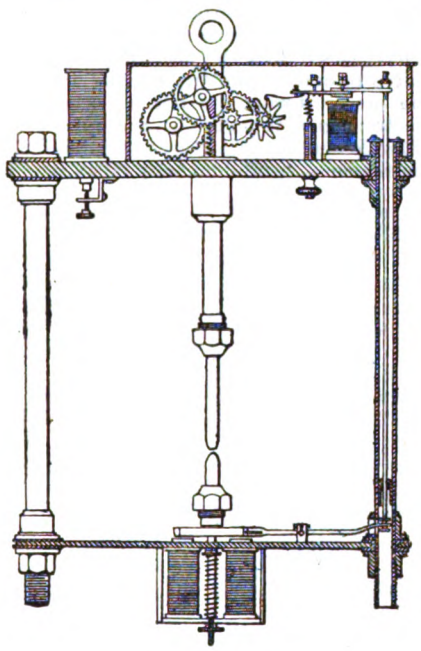

Fig. 3.—Breguet Lamp.

circuit. For if the armature of this electromagnet be held back by a spring or weight which only just counterbalances the pull of the magnet when the current is normal, the weakening the current will at once cause a movement of the armature which may be utilised to relax a clutch, lift a detent, or release an escapement. And it is also obvious that in this case it is possible to arrange the same electromagnet which strikes the arc to actuate the feed. Examples of the use of a single main-circuit electromagnet to actuate both the striking and the feeding mechanisms are to be found in the Serrin lamp, in the Gülcher lamp, and in the Brush lamp as arranged for parallel working.

(2.) *For Lamps in Series.*—Assuming that the dynamo is doing its duty, and keeping the current constant, then in this case the lamp mechanism must be responsible solely for keeping constant the potential between the terminals. Whenever by reason of the burning away of the carbons the arc lengthens and offers more resistance, if the same current is still supplied to it and forced through this greater resistance it will burn more brightly, and the difference of potentials between the terminals of the lamp will rise above its normal value. The lamp must then automatically bring its carbons nearer, and readjust the potentials to the proper number of volts. It is obvious that the appropriate device to actuate the feeding mechanism must, in this case, be something that can play the part of a voltmeter; and will actuate the mechanism when the volts rise above their normal value. Practical voltmeters are of two kinds; (*i*) those which depend on the magnetic effects of the current that will flow through a wire of high resistance placed as a shunt across the two points between which the differences of potential exists, and (*ii*) those which depend on the heating effects of the current in such a wire. Either of these effects may be used to control the feeding mechanism of arc lamps; that is to say, the feed must be controlled by a shunt circuit, which will actuate the mechanism as soon as the potential rises above its normal value. The usual device is an electro-magnet (or solenoid) of fine wire, and of high resistance (from 200 to 450 ohms), the armature of which is counterbalanced by the force of a spring, or by gravity, or by an opposing main circuit electro-magnet (or solenoid). An alternative device, not, however, in general use, is a long thin platinum wire, which when heated by a current above the normal value will expand and actuate the feed. Thermal expansion has been attempted as a method of regulation by several inventors. [Lontin 2074[77]; Siemens, 2281[78] and 2110[79]; Munro, 1626[82]; Edison, 2072[82]; Pollak, 1888, &c.]

In the following table are comprised the several electrical arrangements for controlling the feeding mechanism:—

(1.) *Constant Potential Lamps (for Parallel Working).*—(*a*) Series electro-magnet, same as used for striking (Serrin, Gülcher, Brush, Crompton, &c.). (*b*) Series electro-magnet, separate from the striking electro-magnet (Fontaine). (*c*) Differential arrangement. Series winding partly opposed in shunt winding, on separate cores or parts of mechanism (Lacassagne and Thiers, 2456[56]; Siemens, Brockie-Pell). (*d*) Ditto, but wound on same cores.

(2.) *Constant Current Lamps (for Series Working).*—(*a*) Shunt electro-magnet alone, acting against gravity or spring (Lontin, 1877; Lever). (*b*) Shunt electro-magnet separate from the striking (series) electro-magnet (numerous lamps: Breguet (Fig. 1), Crompton "E," Sellon, Gramme, Pieper). (*c*) Differential arrangement: Shunt winding pulling against series winding on separate part of mechanism. (Lacassagne and Thiers, Siemens "differential," Pilsen, Crompton-Crabb "DD," Thomson-Houston, Brockie-Pell, Kennedy.) (*d*) Differential winding: (Numerous lamps, Brush, Weston, "Simplex.")

The typical arrangement of circuits for lamps that are to be run on a system of arc lighting in series is shown in a generalised diagram in Fig. 4. The striking coil is in the main circuit; the feeding

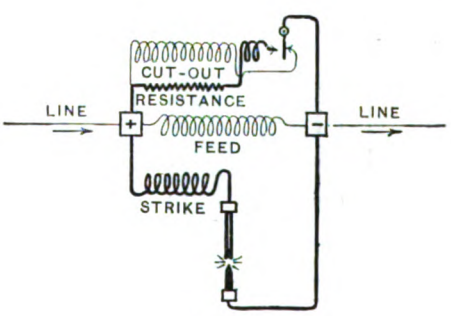

Fig. 4.

coil is a shunt, which if wound on the same series coil in any of the differential systems must be so wound that the currents circulate in opposing senses. There is also added a cut-out circuit, having both a shunt coil and a small series coil; but these must be so wound as to help one another's magnetic power, and the small series coil must itself be a shunt to the main circuit of the lamp.

We are now prepared to enter upon the mechanical devices which have been suggested for the feeding-mechanism of lamps. These are so varied, and run so curiously into one another, that no classification of them is entirely satisfactory. In a very large class of lamps there is a train of wheel work usually driven by the weight of the descending carbon rods, the last member of the train being controlled through a detent or brake, by the electro-magnet that is responsible for the feeding of the lamp. Most, but not all, of these lamps have a rack upon the upper carbon rod to drive the train; but the rack lamps differ greatly amongst themselves. Again, there is another class of lamps in which the upper carbon rod is smooth, but is assisted and controlled in its descent by a clutch or clamp, the clutch or clamp being in turn controlled by the feeding electro-magnet. But there are also rack lamps in which a clutch or clamp is applied, not to the rod itself, but to a wheel driven by the descending rack. There are, however, certain main features of classification about which there need be no ambiguity.

Feed Motions.

(1.) *Rack and Train controlled by*—(*a*) Star wheel and detent (Staite, 18783[47]; Foucault-Duboscq; Serrin, 653[58]. (*b*) Fly and detent (Staite, 1848; Duboscq, 1855). (*c*) Brake-wheel and brake (Chapman, 739[55]; Crompton, 346[82]). (*d*) Escapement with pedulum or balance and detent

Digitized by Google

(Siemens, 4949[78]; Harding, 3166[81]; Waterhouse, 5185[81]). (*e*) Escapement and paddle (Waterhouse, 5185[81]). (*f*) Governor with detent or moderator (Waterhouse, 5185[81]). (*g*) Magnetic brake-wheel or detent (Brockie, 1713[82]; Harling, 3473[81]). (*h*) Liquid brake (Hopkinson, 153[81]).

(2.) *Clutch or Clamp on Rod.*—(*a*) Tilting ring, tilting eyelet, &c. (Slater and Watson, 212[82]; Brush, 2003[78]; Lumley, 1249[82]; Lever, 2092[82]; Thomson-Houston; Waterhouse, &c.) (*b*) Split cone gripped by fork (Slater and Watson, 212[82]). (*c*) Split nozzle forced into cone mouthpiece (Bürgin, 4820[81]). (*d*) Split tube held together by oblique levers (Rogers, 3236[82]). (*e*) Gripping springs at side (Lever, 3599[81]; Munro, 1626[82]). (*f*) Gripping fingers (Roberts, 14198[82]; Joel, 5157[79]; "devil's claws," Harding, 3166[81]). (*g*) Washer jambed by ball bearing (Young, 1689[82]; or roller, Newton, 4559[81]). (*h*) Tilting clamp or nipping clamp (Common, 626[82]). (*j*) Nipping lever (Grimstone, 1670[81]; Mondos, 5490[81]). (*k*) Scissors lever (Joel, 3970[84]; Jarman, 563[82]; Gerard-Lescuyer, 2992[82]). (*l*) Spiral spring surrounding rod (Keilhotz, 1886; Thouvenot, 1887). (*m*) Forward-pointing springs (lobster-trap) (Newton, 1623[83]; Clark-Bowman, 1182[83]; Holmes, 769[86]; Hawkes, 157[82]).

(3.) *Clutch-wheel or Brake-wheel.*—(*a*) Nipping lever outside brake-wheel (Gramme, 1861; Common and Joel, 1040[81]; Brockie, 4419[82]). (*b*) Nipping lever inside rim of wheel (Union Company, 392[82]; Brockie, 4419[82]). (*c*) Elastic band brake (Statter, 2985[83]). (*d*) Elastic internal ring brake (Siemens, 6957[87]; Fein, 1888). (*e*) Wheel lifted against brake or detent (Bürgin, 4820[81]). (*f*) Brake-wheel lifted upon brake-lever (Gümpel, 253[81]; Crompton-Crabb, 2539[83]). (*g*) Friction-pad on rim of wheel (Abdank, 1882).

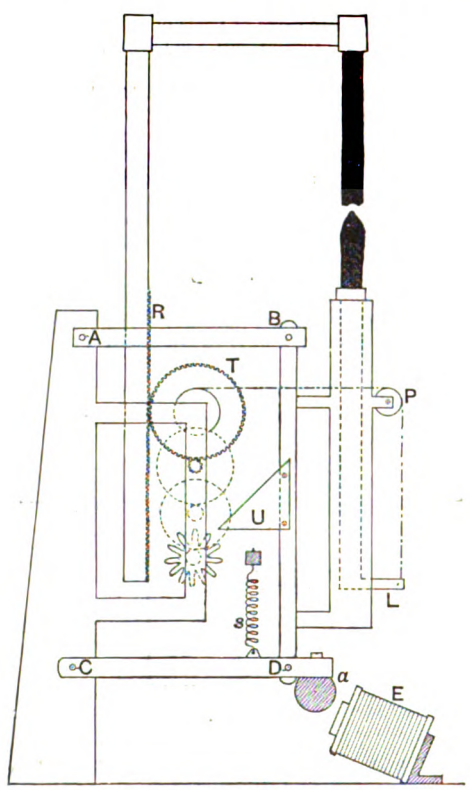

FIG. 5.—Serrin's Lamp.

(4.) *Screw Motion.*—(*a*) Screw worked by weight of upper rod (Hopkinson and Muirhead, 153[81]; Cance, 3976[81]; Akester, 2419[82]). (*b*) Screw worked by motor (Tchikoleff, 1874). (*c*) Screw worked by step-feed (Street-Maquaire, 9666[85]). (*d*) Screw worked by vibrated wheel (Siemens, 6987[87]).

(5.) *Cord and Pulley Motions.*—(*a*) Cord and pulley to core of solenoid (Archereau, 1848; Jaspar, 83[79]). (*b*) Cord and pulley connecting carbons, with long-travel solenoid (Pilsen lamp, 1397[80]; Doubrava, 1033[86]). (*c*) Cord gripped by controlling cam (Harding, 4590[79]). (*d*) Cord and pulley for differential feed (Weston, 1883; Kennedy, 1888).

(6.) *Step-by-Step Motions.*—(*a*) Step detent worked by electro-magnet (Deleuil, 1856; Brockie, 898[82]; Gatehouse and Kempe, 2569[82]; Kennedy, 5524[81]).

(7.) *Magnetic Clamps and Clutches.*—(*a*) Tilting magnet clutch on rod (Roberts, 14198[82]; Gulcher, 2038[81]). (*b*) Magnetic clamp on brake-wheel (Harling and Hartman, 3473[81]; Hardt, 1886).

(8.) *Electric Motor Action.*—(*a*) Motor screws carbon up or down (Tchikoleff, 1874, and 2198[81]; Maquaire, 1889). (*b*) Winds up with cord or rack (Andrews, 2321[79]; André, 2764[80]; Bousfield, 523[79]; Brequet, 1879). (*c*) Motor itself controlled by shunt magnet (Thomson-Houston, 315[80]). (*d*) Motor with copper damper (Thury, 1888).

(9.) *Hydrostatic and Pneumatic Action.*—(*a*) Carbons controlled by admission of liquid or gas (Lacassagne and Thiers, 2456[56]; Hopkinson, 3509[80]; Leibold, 1886; Sedlaczek, 1883).

(10.) *Vibrating Feeds.*—(*a*) Make-and-break lever vibrate forward-pointing springs (Newton, 1623[83]; Pieper, 4647[86]; Holmes, 769[86]). (*b*) Make-and-break lever actuates escapement (Harding, 3166[81]). (*c* Make-and-break lever actuates detent on train (Gramme, 1880). (*d*) Make-and-break lever hammers rod through clutch (Letang, 5509[87]). (*e*) Make-and-break lever works internal clutch-wheel feed (Fein, 1888). (*f*) Make-and-break lever drives pallet and screw feed (Siemens (Alteneck), 1885).

(11.) *Periodic Feeds.*—(*a*) Periodic drop of upper carbon and lift through definite range (Brockie, 898[82] and 1713[82]). (*b*) Periodic currents to magnet sent through second wire (André, 4948[81]).

(12.) *Continuous Feeds.*—(*a*) Clockwork step feed, length of stroke varied by magnet (Brockie, 898[82]). (*b*) Pendulum or governor, having rate varied by magnet (Waterhouse, 5185[81]). (*c*) Rack-train controlled by magnetic retardation on copper wheel (Niaudet, 1878).

(13.) *Hammering Feeds.*—(*a*) Rod driven through clutch by vibrating hammer (Letang, 5509[87]; Capito and Hardt, 1887). (*b*) Ditto, by tilting lever (Jolin, 3570[83]). (*c*) Ditto, by magnetic pile driver on rod (King, 1888).

Outside the classification adopted above are several well-marked features of mechanism; one of these is the *parallelogram motion*. A typical case of this is afforded by the well-known Serrin (653[59]) lamp (Fig. 5). A jointed parallelogram is constituted by the pieces which meet A, B, C, D. The side A C, is fixed, being part of the frame, whilst the levers A, B, C, D, rise and fall through a small angle, carrying with them the upright B D. To this upright is fastened a sleeve, through which the lower carbon holder passes. This moving parallelogram is held up by a spring, *s*. When the electromagnet E (in main circuit) attracts its armature, *a*, the parallelogram, and with it the lower carbon, sinks, and so the arc is struck. At the same instant a projecting triangular detent, U, engages against the star wheel of the driven train and locks it, so that the upper carbon cannot descend. As the carbons are consumed the current is weakened, owing to the increasing resistance of the lengthening arc, and the electromagnet lessens its attraction; consequently the parallelogram gradually rises, until a moment occurs when the detent ceases to lock the star-wheel. The upper carbon-holder is now free to descend a little, driving the train of wheels, shortening the arc, restoring the normal current, and so again causing the electromagnet to pull down the parallelogram and lock the wheels. Parallelogram motions are to be found also in Bürgin's (4820[81]), and in Siemens' pendulum lamp (4949[78]).

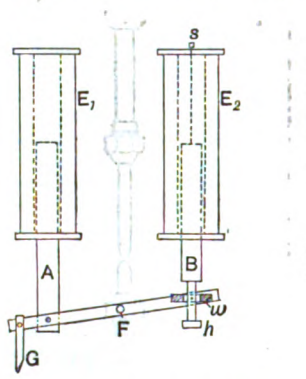

FIG. 6.—See-saw or Brockie-Pell Lamp.

Another characteristic mechanism is the *see-saw* lever. Fig. 6 shows the form used in the Brockie-Pell lamp (12681[85]). The earliest use of the see-saw, attracted at opposite ends by series and shunt magnets respectively, occurs in the lamp of Lacassagne and Thiers (2456[56]); whilst modern examples are Weston's lamp, the Thomson-Houston lamp (Fig. 14), and Fein's lamp of 1883. [Also Moffat and Chichester, 3441[81]; and Chadburn, 2755[81], where the see-saw works a clutch]. A compact modification of the see-saw mechanism occurs in one form of Weston's lamp, and again in Kennedy's lamp of 1888, Fig. 10. Here the lever is replaced by a pulley over which passes a cord or ribbon of metal. In this lamp the shunt solenoid is furnished with a plunger core, whilst the series solenoid on the left has a plunger and an external iron mantle to increase its power. The smaller pulley communicates the motion to a clutch. The advantage of the see-saw, and of its pulley equivalent, is that such an arrangement enables the lamp to be used as either a constant potential lamp or as a constant current lamp. In the former case the shunt coil holds up its end, whilst the see-saw is operated by the variations of the current in the series coil. In the latter case the actions are the inverse of this.

The *rack-train* mechanism which forms the first-class in the preceding list, presents two special points. As this mechanism is in itself non-retractile, and can only propel the carbons forward, it cannot be used with non-homogeneous carbons of second quality, unless special provision is made in the striking mechanism of the lamp for a retractile movement. There is nothing retractile, for example, about the Breguet lamp (Fig. 3), but there is about the Serrin (Fig, 5), for the lower carbon holder, which descends

Digitized by Google

to strike the arc) is never held tight down by the electro-magnet, but takes up a position of equilibrium. The other point is that in these rack-train lamps some device is requisite to lock the train at the instant of striking, otherwise the feed motion would neutralise the strike motion. In some lamps (Breguet, Sellon, &c.), there is a mechanical connection from the striking part to lock the feed. In some other lamps the action is performed electrically. In the De Puydt lamp a pin on the train frame engages with a forked connecting piece from the feeding lever.

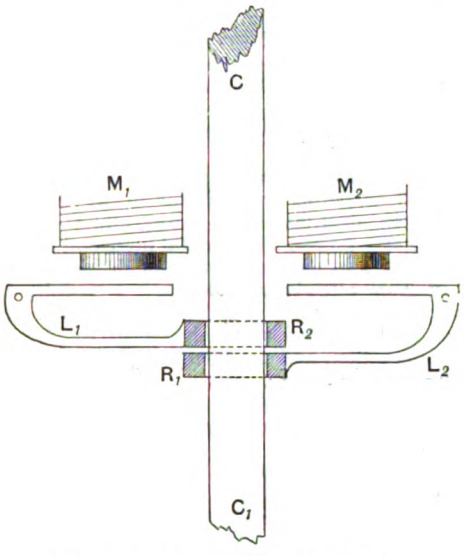

FIG. 7.—Slater and Watson's Clutch.

A characteristic arrangement, applicable to rack-train lamps, is that in which, for the purpose of striking the arc, the whole train mounted in its framework, together with the rack and the upper carbon rod, is bodily lifted by the use of an electro-magnet in the main circuit. (Crompton, 346[82]); Fyfe and Main, Hochhausen, Gümpel, Berjot, Wood, Maxim, &c.) More neat is the method of rocking the train bodily around the axis of one of the wheels of the train (Brockie, 2370[82]; and De Puydt).

Passing from the *rack-train* lamps to the *clutch* lamps, it may be noted how much ingenuity has been expended in attempting to find a form of clutch which will prove reliable under all conditions of working. Two of the very earliest forms of clutch mechanism are worth recalling in this connection. These are both due to Slater and Watson (212[52]). The first (Fig. 7) shows a carbon rod sliding through a couple of rings or eyelets, which are tilted by the attraction of an electro-magnet to grip and raise the rod. In the second (Fig. 8) the clutch consists of a split conical washer, the two halves

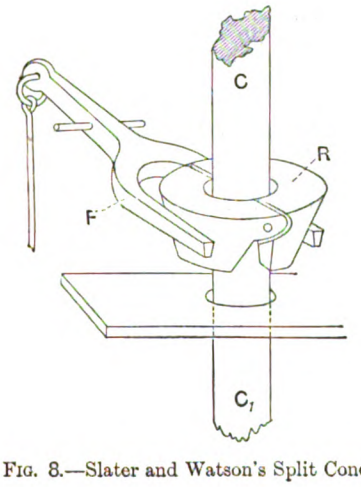

FIG. 8.—Slater and Watson's Split Cone.

of which are hinged together. These are compressed by the rising of a fork, which nips and raises them. The tilting ring introduced by Brush is too well known to need comment. Lever's modification of the tilting ring is shown in Fig. 9, the rim below the ring causing the thrust to act more obliquely at first, and allowing the clutch to work even when the aperture is considerably worn. In the latest forms of this clutch the ring has a tail-piece which is hinged to the frame of the lamp. Another successful form of tilting clutch is shown in Fig. 10, which represents the mechanism of Kennedy's lamp. The clutch has a long tail, provided with an adjusting screw to regulate its position, and bears against the carbon-rod by a slender spring, *s*, above. It is worked by a thin cord, *d*, running over a pulley in connection with a differential arrangement of shunt, S, and series, M, solenoids described above.

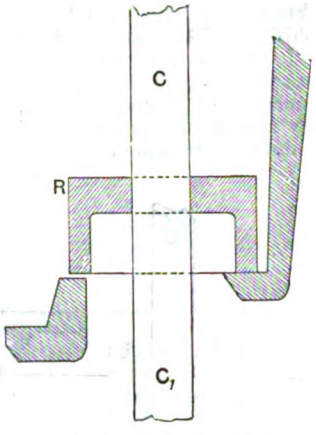

FIG. 9.—Lever's Clutch.

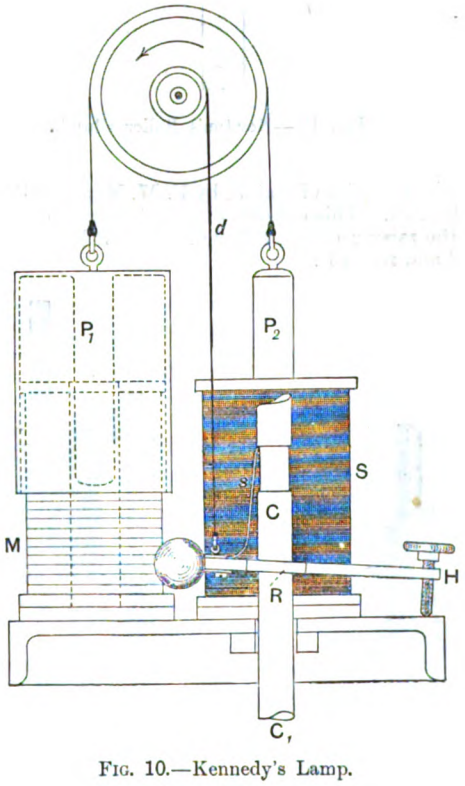

FIG. 10.—Kennedy's Lamp.

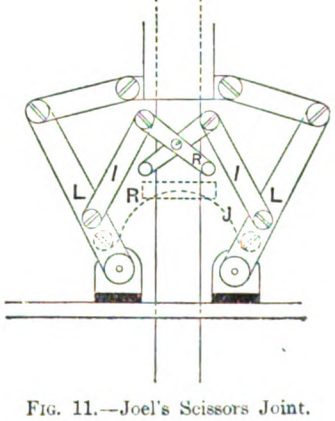

FIG. 11.—Joel's Scissors Joint.

A clutch provided with a spring that bears against the carbon rod is also found in the Clarke-Bowman lamp (1182[83]), the feeding in this case being accomplished whilst the clutch is held up, by giving to it a mechanical vibration. In the Kennedy lamp the spring on

Digitized by Google

the clutch also serves the purpose of finally arresting the descent of the carbon holder, catching on a groove cut around its upper end when the carbon pencil is all consumed. Another simple clutch with spring mounting, worked by the mutual repulsion between two similarly magnetised cores, has been devised by Swinburne (11893[86]).

Clutches of the knee-lever type have been devised by Lorrain (183[83]) and Joel (3970[84]). The more complex "scissors joint" levers, used in one of Joel's lamps, are drawn in Fig. 11. Their action is obvious, as their upper end is raised by the upward pull of the electro-magnet or solenoid they grip, and raise the carbon rod, and they relax their grip on being lowered to feed the arc. Very similar devices are found in Gerard's and Jarman's lamps.

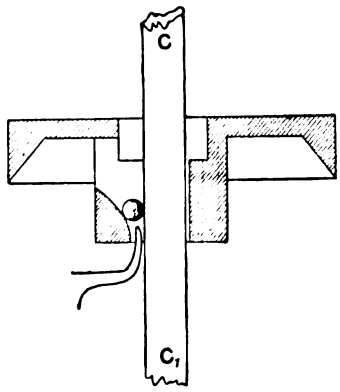

FIG. 12.—Newton's Roller Clutch.

An ingenious species of clutch, by F. M. Newton (4559[81]), is illustrated in Fig. 12. This consists of a ball-bearing or roller-bearing, which on the raising of the collar in which it lies jams against the carbon rod and raises it.

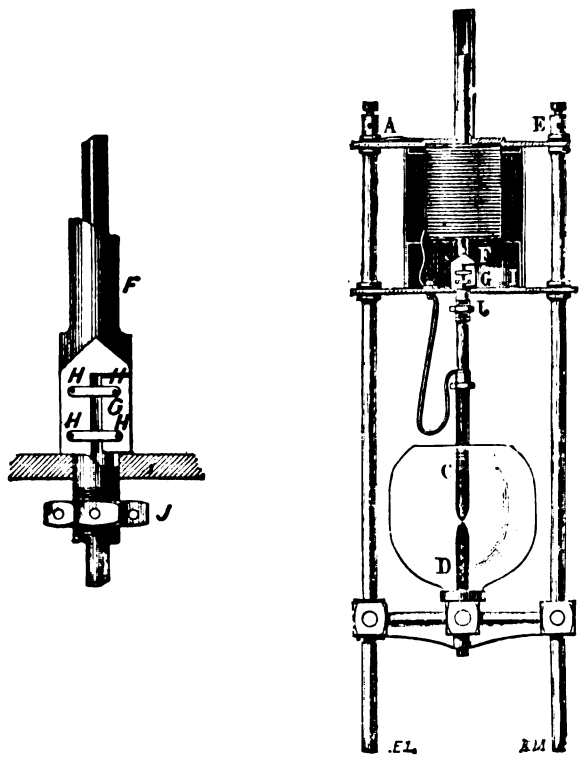

FIG. 13.—Rogers' Clutch.

Another extremely simple clutch (Lorrain, 639[83]), consists of a plunger working horizontally through a solenoid, pressed sideways by a spiral spring against the carbon rod; the pressure of this is taken off, when feeding is required, by the pull due to the current in the solenoid, which is connected as a shunt. Rogers' (3236[82]) simple and very efficient form of clutch consists of a split tube, the parts of which are connected together by a pair of oblique links, making a sort of parallel motion. This form is shown in Fig. 13.

(To be continued.)

ECONOMICS OF PLANNING AND CONSTRUCTING ELECTRIC LIGHT AND POWER STATIONS.*

BY ALEX. P. WRIGHT.

(Continued from page 513.)

The estimate of cost of station already given, it must be understood, is approximate only, and made without reference to plans. It is merely preliminary. The estimate is intended to more than cover the immediate wants of the plant up to the extent of 1,000 horse-power and corresponding dynamo capacity; the station being designed for an ultimate 1,300 horse-power capacity.

The following three estimates are also preliminary, and are based on the conditions enumerated above, which may be respectively designated A., B. and C.

A. being for the immediate output 600 horse-power, B. being for an increased output as provided for in the estimate of cost of plant to the extent of 1,000 horse-power, and C. for the ultimate capacity 1,300 horse-power, with capital increased to $250,000.

The estimate of horse-power hours are deduced from curves of which the diagram already considered is a sample, and in each change has been made in due proportion to the increase.

It has been first assumed that only a small dividend be paid the first year of operation, and an increasing one with the increases which it is assumed will come.

The power required for a full arc lamp is taken as 1 horse-power, for a divided arc 3-4 of a horse-power, and for incandescent lighting 10 lamps are assumed per horse-power.

For motor work it is assumed that 1 horse-power actual will supply 2 horse-power of motors. As a matter of fact, with a sufficiently large number the estimate of power required is smaller, and it may be further stated that not only are all these assumptions of power high, on the general principle that, in estimating, cost should be put high and revenue low; but they can be borne out by the records of over twelve months' run, in a place for which this might be the plan to be taken.

In the course suggested in these articles the time for minute estimation will come after the preliminary estimates and plans based upon them; and it must be borne in mind that in all the outlines so far given and which immediately follow, that they are such as might be elucidated in a preliminary discussion, and as if taken without premeditation. It is proposed to conclude with two or three plans in such detail as the space will allow with more minute estimates following them, with such remarks upon quality of work and material as may arise in discussion of the subject; in fact it has been the writer's object to deal with this matter much as it might be dealt with in the way of discussion, previous to deciding upon a plant.

Before proceeding with more detailed and final plans it may be interesting to fix rates for lighting of all classes and power, and then to estimate what profits such rates would bring in each of the three cases A, B, and C.

(To be continued.)

ON AN EFFECT OF LIGHT UPON THE MAGNETISATION OF IRON.*

BY SHELFORD BIDWELL, M.A., F.R.S.

Several experimenters in the early part of the present century tried to magnetise iron and steel by the action of light,† but I do not know of any recent attempts in this direction, and of late years the thing has been generally regarded as impossible. Under ordinary circumstances there can be little doubt that this is the case, but, if a certain condition is fulfilled, we might, I think, expect to find some evidence of the action of radiation upon the magnetism of iron.

The condition is that the susceptibility of the bar A B to be operated upon shall be greater (or less) for a magnetic force in the direction A B than for an equal one in the direction B A. This Paper contains a short preliminary account of a series of experiments which have been undertaken with iron bars having this property. Much yet remains to be done, which will require a considerable amount of time, and for which special apparatus must be constructed. In the meantime the results already obtained appear to possess sufficient interest to justify their publication.

The method of preparing the bars is as follows :—A piece of soft iron rod, which may conveniently be 10 or 12 cm. long, and from 0·5 to 1 cm. in diameter, is raised to a bright yellow heat, and slowly cooled. When cold it is placed inside a solenoid, through which is passed a battery current of sufficient strength to produce a field of about 350 or 400 C.-G.-S. units. The iron when removed from the coil is found to be permanently magnetised, and its north pole is marked for the sake of distinction with red sealing-wax varnish. The bar is then supported horizontally, and in an east and west direction behind a small reflecting magnetometer, and over it is slipped a coil which is shunted with a rheostat, the resistance of which can be gradually increased from 0 to 26 ohms. The coil can be connected by a key with a single battery cell, which is so arranged as to produce a demagnetising force inside the coil. The resistance of the rheostat is slowly raised, so that more and more current passes through the coil, the battery key being alternately lifted and depressed until the magnetometer indicates that the iron bar as a whole is perfectly demagnetised. The strength of the demagnetising force required varies according to circumstances ; it is generally about one-thirtieth or one twenty-fifth of the original magnetising force.

After this treatment the iron rod does not differ, so far as ordinary tests will show, from one which has never been submitted to magnetic influences. Nevertheless, as is well known, it possesses certain properties which distinguish it from a piece of really virgin iron. In the first place, the magnetisation induced by a force acting in such a direction as to make the marked end a north pole is greater than that caused by an equal force in an opposite direction. Again, if such a bar be held horizontally east and west (to avoid terrestrial influences), and tapped with a mallet, the marked end at once becomes a north pole. A similar effect follows if the rod be warmed in the flame of a spirit lamp. Lastly, if it be placed inside a coil and subjected to the action of a series of rather feeble magnetic forces, of equal strength but alternating in direction, the marked end will generally become a north pole, even though the last of the alternate forces may have tended to induce the opposite polarity.

A rod treated as above described appears to be remarkably sensitive to the action of light. When such a rod is placed behind the magnetometer, and illuminated by an oxyhydrogen lamp about 70 cm. distant, there occurs an immediate deflection of from 10 to 200 scale divisions,‡ the magnitude of the effect varying in different specimens of iron. As the action of the light is continued the deflection slowly increases. When the light is shut off, the magnetometer instantly goes back over a range equal to that of the first sudden deflection, then continues to move slowly in the backward direction towards zero.

The first quick movement I believe may be due to the direct action of radiation, and the subsequent slow movement to the gradually rising temperature of the bar. With a thick rod (1 cm. in diameter) the slow movement is barely perceptible, extending over only one or two scale divisions in the course of a minute, the spot of light becoming almost stationary after the first sudden jump. With a thin rod the sudden effect is generally smaller, while the slow after effect is greater, and may continue until the spot of light passes off the scale.

As a general rule the magnetic effect is such as to render the marked end of the rod a north pole ; occasionally, however, it becomes a south pole, but in such cases I have always found that the polarity is comparatively feeble. It may even happen* that the marked end becomes north when certain portions of the rod are illuminated, and south when the light acts upon other portions. This is probably due to irregular annealing and a consequent local reversal of the direction of maximum susceptibility ; it indicates that the light effect is local, and is confined to the illuminated surface. In one remarkable specimen, which happens not to have been annealed at all, the sudden effect and the slow effect are in opposite directions. When the light is turned upon this rod there is at first a sudden deflection of twenty magnetometer-scale-divisions to the left, the spot afterwards moving slowly and steadily towards the right. When the light is shut off there occurs at once a jump of twenty divisions further towards the right before the spot begins to move back in the zero direction.

Some attempts have been made to repeat the experiments with light polarised by means of a Nicol's prism ; but, either because the largest prism at my disposal was too small (its aperture being barely 2 cm.), or because too much of the radiant energy was absorbed by the spar, I failed to get any magnetic effects whatever with the prism in either position.

[Prof. Silvanus Thompson has quite recently been kind enough to lend me a very large and excellent Nicol's prism. From a few experiments already made with this instrument, it appears that the action of the light is quite independent of the plane of polarisation.—March 16.]

There can be no doubt whatever of the reality of the effects here described ; they are perfectly distinct, and are at any time reproducible with certainty. The only question is how much of them is primarily caused by the action of light, and how much by mere incidental change of temperature. But taking all the circumstances into consideration, I think the evidence is in favour of the conclusion that the *instantaneous* magnetic change, which occurs when a prepared iron bar is illuminated, is purely and directly an effect of radiation.

* Paper read before the Royal Society yesterday (Thursday) evening.

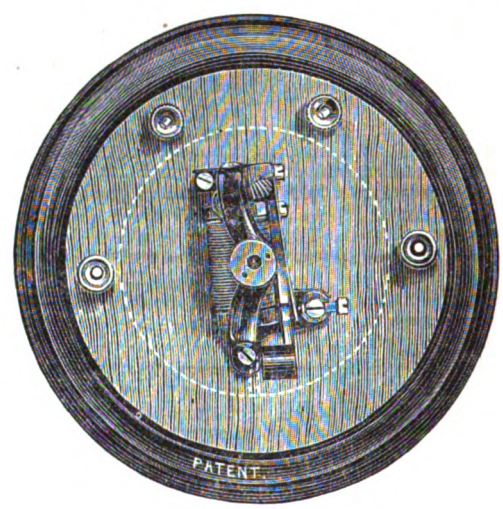
† Chrystal, *Encycl. Britann.*, Vol. XV., p. 274, mentions the following names :—Morichini, Mrs. Somerville, Christie, Riess, and Moser.

‡ The magnetometer mirror was 1 metre distant from the scale, and each division = 0·64 mm. ($\frac{1}{40}$ inch).

* This has been observed in two specimens.

BERRY'S IMPROVED ELECTRIC BELL.

The accompanying figure shows the working parts of an improved form of electric bell brought out by Mr. F. H. Berry, of



Percival-street. It is very neat and compact, the whole of the working parts being hidden beneath the dome, the position of which is shown in the figure by the dotted line. A single bobbin only is used to energise the magnet, and a powerful ring is obtained with one small Leclanché.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 9th*, 1889.

It might be expected that after the recent vigorous pronouncement by electric light men at Chicago against the subways, the various municipal authorities would be desirous of going a little more slowly in forcing the companies into the subways. But the contrary appears to be the case. In this city the Mayor, as a member of the Subway Board, has taken to his new duties with a *verve* and a zest that are in remarkable contrast with the apathy shown by his predecessor. Mayor Grant figures at the present time very much like some of those Eastern despots whose leading remark in conversation was "Off with his head," for he no sooner hears that some poor offender has been guilty of tardiness in getting into the conduits than he immediately threatens him with all the penalties of the law and several other things besides. The Subway Board appear very glad to have this assistance from the Mayor, but it begins to look as if his precipitancy will presently land them in an awkward predicament. This week the meeting of the Board was the scene of a terrible conflict of ugly words between the Mayor and Commissioner Gibbons and Mr. Lynch, the president of the United States Company. Mr. Gibbons made certain statements as to the contumacious behaviour of the company, whereupon Mr. Lynch gave him the lie direct, and when Mr. Gibbons added that he based his statement on his conscience and his judgment, Mr. Lynch told him that it was "a poor foundation." As may be easily believed such amenities as these are not leading to a very peaceful solution of the difficulties that beset the underground wires in this city. In Philadelphia there is prospect of a not less unenviable state of affairs. A Bill is now pending before the Pennsylvania Legislature, providing, under a penalty of $500 a day for delay, that all the wires in cities of more than 30,000 inhabitants in that State shall be placed underground by August. This is, of course, the sheerest absurdity in the way of legislation; but it begins to look as though the law may pass, in which case the authorities in Philadelphia will have to bury 12,000 miles of wire in less than six months, at a cost certainly exceeding $5,000,000, tearing up the streets and paving in every direction, paralysing all kinds of electric service, and rendering life a misery and a burden as much to citizens as to the companies at whom the blow is aimed.

Quite an interesting event occurred at Baltimore a few days ago, during the celebration of the thirteenth anniversary of Johns Hopkins' University, when Prof. H. A. Rowland delivered an address on "Modern views with respect to electric currents." This address, which has not yet been given out for publication, placed him in line with Sir William Thomson and others in regard to the latest theories on the nature of electricity, and was rendered the more valuable from being illustrated by a number of experiments. I think I may best give an idea of Prof. Rowland's views by the following brief quotation:—"We have thus done away with action at a distance, and have accounted for magnetic action by a change in the intervening medium, as Faraday partly did almost fifty years ago. For this change in the surrounding medium is as much a part of the electric current as anything that goes on within the wire. When we use the electric light to illuminate our streets it is the luminiferous ether which conveys the energy along the wire, as well as transmits it to our eye after it has assumed the form of light. When the wire falls to the ground, as it is sure to do sometimes, and it is touched by some unfortunate man or horse, it is the luminiferous ether which sounds his death knell. We step upon an electric street car, and feel it driven forward with the power of many horses, and again, it is the luminiferous ether whose immense force we have brought under our control and made to serve our purpose—no longer a feeble, uncertain sort of medium, but a mighty power, extending through all space, and binding the whole universe together, so that it becomes a living unit, in which no one portion can be changed without ultimately involving every other portion."

An interesting Paper was presented at the last meeting of the New York Railway Club by Dr. H. R. Waite, of the Julien Company, on "Electric Train Lighting." Dr. Waite mentioned the fact that the Railway Car Lighting and Signal Company, using the Julien battery, had recently fitted up two vestibule trains on the Chicago, Milwaukee and St. Paul Road with a lighting plant on the method devised by Mr. Barrett, comprising a Brotherhood engine and a special generator furnishing current to 448 cells placed in convenient numbers in trays beneath the fourteen cars of each train. The same system of supplying to the battery has been in use for some time on the Connecticut Riverhead Railroad, and has made a very favourable showing of expenses as compared with oil lighting. The cars illuminated are in this case those employed for the ordinary passenger traffic. Dr. Waite's figures show that oil lighting for the same train on that road takes a total outlay of $925 per annum, whereas the cost by electricity was $330, or adding the expenditure for coal, &c., in generating steam $486, leaving a difference in favour of electric lighting of $439 per annum. In other words, for this ordinary train electric lighting costs $6·84 per lamp per year of 310 days, or 2·2 cents per lamp per day, while the oil lamp costs $13·3 per lamp per annum, or 4·2 cents per lamp per day. Of course electric lighting on special trains would be more costly than on ordinary trains, but even there, it stands to reason, the advantages would be on the side of the electricity on all the scores of safety, health, comfort and high illuminating efficiency. It appears from Dr. Waite's Paper that the depreciation on the entire electric plant of this character amounts to less than 5 per cent. per annum, the plant is question being estimated at an original outlay of $2,500.

There is remarkable activity with the opening of spring in the electrical railway field, in fact the boom in this department promises to be something terrific. I notice that the *Electrical World* illustrates this week no fewer than six new railroads, while its columns week by week contain notes of scores of new projects everywhere. It is mentioned in one of the articles that on the electric railroad at Wichita, Kan., a brush has been in continuous use on one of the motors for the period of 65 days, making a total run of 4,300 miles. This is pretty good work for a motor brush, and I see it stated that the Thomson-Houston Company are now introducing carbon brushes in place of those made of copper. The idea of using carbon brushes instead of copper on dynamo electric machines is not a new one, and, in fact, seemed with the progress of the art to have fallen into disfavour, but the rapid introduction of motors has given it new life and popularity. While the brushes of the dynamos are generally under frequent inspection and easy to get at, those of a motor which is placed under the car are generally hard to get at and not very easy to see. Hence it happens that carbon has come into use again, and the record made with it on several Thomson-Houston roads appears to be most encouraging for its more extended use. It is stated that the carbon brush or block has a longer life than the copper brush, and has a much better effect upon the commutator, causing it to present a smooth glazed surface, which virtually requires no oil or other lubricant.

I believe I have already advised you of the fact that an attack has been made on the Edison patents in Canada by the Westinghouse and other interests, on the ground that the main patent there is null and void from the failure of the company to manufacture its apparatus within one year, as required by the Canadian patent law. Information reached this city to-day (Friday) to the effect that Mr. Pope, the Commissioner of Patents, before whom a large amount of evidence *pro* and *con* has been submitted, has decided that the patent has been invalidated for the reasons named, and that it must therefore be cancelled. The effect of this decision is to throw the incandescent business open in Canada, and it is also claimed that it will have a reflex action on the status of the patent in this country.

Although we have nearly completed the first quarter of the year, and have our usual number of murders, no case has yet occurred for record or study of execution by electricity. It might seem as though the law had fallen into "innocuous desuetude," but I suppose we shall hear something about it soon. In the meantime one or two of the other States such

Digitized by Google

as Ohio and Missouri, are prepared to follow the example of New York, but in Illinois a considerable spirit of opposition to the idea has manifested itself. At a meeting of doctors during the past week in Chicago, the subject came up for discussion, and the medical men, by a large majority, declared themselves against electrical executions, voting, moreover, to send their resolutions on the subject to the Governor of the State.

I hear from Boston that the greatest interest is taken there in commercial and electrical circles in the development of the Thomson welding system. The factory at Lynn, adjoining the huge works of the Thomson-Houston Electric Company, is already full of machinery, and is as busily occupied as possible in the manufacture of the apparatus. The stock of the company is in great demand, and I believe it is now quoted at a premium of 200 or 300 per cent. There seems no reason whatever to doubt that the company has a great career before it, and that there is destined to be an immense demand for electric welding.

Mr. Charles G. Burke, who is well-known here as a persistent experimenter in telegraphic and cable improvements, has been conducting for about a year a series of elaborate experiments and trials with his new cable relays over the cable of the Direct United States Company, between Rye Beach, New Hampshire, and Halifax, Nova Scotia. Mr. Burke was in this city last week, and reports having succeeded in demonstrating the fact that Morse telegraphy by sound is practicable over the longest cable, at a speed at least as great as that of the Mirror and Siphon Recorder. On February 17th he tried one of his relays for the first time on the main Atlantic cable of the same company between Halifax and Ireland, a distance of 2,500 miles; and a local circuit and an ordinary Morse sounder were operated without difficulty. It is stated that the make and break of the local circuit were just as prompt, firm, and accurate as they would have been on a land line, and this without any increase in the battery power ordinarily used in the operation of the mirror. Mr. Burke is now having a number of instruments completed for the purpose of establishing a complete circuit between New York and London, from which the messages are to be sent direct without the intervention of operators at intermediate stations, and received at their destination by sound in the ordinary manner. It is understood that the Direct Company will have an interest in these improved inventions, and it certainly will be worth having should the statements which I have cited be substantiated to any material extent.

SCANDINAVIAN NOTES.

(FROM OUR CORRESPONDENT.)

The Copenhagen Telephone Company has for some time been in negotiation with the Corporation as to the conditions on which they might be allowed to use the streets for telephone wires. An agreement containing some very stringent clauses has now been entered into. The agreement holds good for thirty years from January 1st, 1888, and after its expiry all wires must be removed, unless fresh arrangements are made. The concession is a most one-sided affair, and it is no wonder that the company required a long time to stomach it.

The minimum charge for inland telegrams in Sweden has been reduced to 50 öre (6¾d.) from the beginning of this year. The result is a vast increase in the number of telegrams despatched. In the town of Norrkögring the inland telegrams during January exceeded those of January last year by 50 per cent., and in Helsingborg the increase was still greater, the figures being 1,065 for January this year, against 515 for January last year, the receipts having simultaneously risen from 529kr. to 753kr.

In Russia every telephone proprietor has to pay an annual tax to the Government of 100 roubles. In some of the Baltic provinces one large payment may take the place of the annual tax; in Reval, for instance, a payment of 9,000 roubles procures the right to erect a telephone. A large Swedish electrical engineer had recently fixed an experimental telephone between two houses in Reval, but had to quit the town with very short notice, leaving his telephone behind him, so as not to be made to pay the fee.

Mr. L. M. Eriksson, of Stockholm, whose telephone is so well known, has recently introduced further improvements in his instrument. Some three years ago Mr. Eriksson constructed a new microphone, with the object of avoiding the somewhat frequent adjustment which was necessary with the older form. The improved microphone consisted of a number of vertical carbon rods resting upon a horizontal one. This instrument did not come into general use, and was never adopted by the Stockholm Telephone Company, but the new telephone of Mr. Eriksson is understood to be a distinct improvement, both as regards the transmission of sound and the adjustment. The membrane presses against some grains of carbon, giving rise to the variable electric resistances during speaking which are necessary for transmission of sound. This form of microphone transmits and moderates the sound exceedingly well. A weak voice seems to be strengthened, and very loud exclamations reach the receiver subdued, but perfectly distinct. The adjustment of the microphone is effected by turning it half round, whereby the carbon grains are made to revolve, resulting in fresh points of contact; it can be fixed on the ordinary telephones, but as the construction has not yet been thoroughly tested for any length of time, it might be premature to guarantee its keeping all the good qualities which the first specimens undoubtedly possess. Should these good points be confirmed by further testing, there can hardly be any doubt that this latest invention of Mr. Eriksson will make a mark.

A Swedish factory (Liljeholmens Stubinfabrik) has commenced to make electric cables. On a recent occasion they delivered 2,200 metres of cable to a Stockholm firm, some with nineteen and some with thirty-six copper wires. The insulation appears to be everything that can be desired, and several important orders have recently been completed.

CORRESPONDENCE.

PROF. JOSEPH HENRY'S RESEARCHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Whilst the recollection of Dr. Lodge's lecture at the Royal Institution is fresh in the memory of those who heard it, permit me to extend a remark which fell from the lecturer with respect to Prof. Henry's observations on inductive discharges. It will be remembered that *apropos* of the impromptu experiment which arose from the unexpected behaviour of the Royal Institution theatre wall paper Dr. Lodge mentioned that Prof. Henry had observed that a discharge in an upper room of a house caused sparks in an independent circuit in a cellar.

The full account of Prof. Henry's observation is to be found in the "Scientific Writings" of Prof. Henry, Vol. I., p. 200 (Washington, 1886), in a short Paper, entitled, "On Induction from Ordinary Electricity and on the Oscillatory Discharge." It was pointed out by Mr. Raine in *The Electrician* of November 2nd, 1888, that Prof. Henry was undoubtedly acquainted with the oscillatory nature of Leyden jar discharges, and that fully fourteen or fifteen years before Sir W. Thomson's important paper in the *Phil. Mag.* Here is the whole passage taken verbatim from Henry's paper referring to inductive discharges:—

"In extending the researches relative to this part of the investigation a remarkable result was obtained in regard to the distance at which inductive effects are produced by a very small quantity of electricity. A single spark from the prime conductor of the machine of about an inch long thrown on the end of a circuit of wire in an upper room produced an induction sufficiently powerful to magnetise needles in a parallel circuit of wire placed in a cellar beneath at a perpendicular distance of 30ft. through two floors and ceilings each 14in. thick. The author is disposed to adopt the hypothesis of an *electrical plenum*, and from the foregoing experiment it appears that the transfer of a single spark is sufficient to disturb perceptibly the electricity of space throughout at least a cube of 400,000ft. capacity, and when it is considered that the magnetising of the needle is the result of the difference of two actions it may be further inferred that the diffusion of motion in this case is almost comparable with that of a spark from a flint and steel in the case of light."

This remarkable experiment of Henry's shows how very near he came to the starting point of the investigations, which have occupied Dr. Hertz for the last few years, and that his notion of an electrical plenum, and the analogy of its disturbance with the diffusion of light, brought him almost within touch of modern views. We must at any rate credit Henry with having a perfectly clear conception of the oscillatory form of the discharge, and with having experimentally, though not

Digitized by Google

with quite definite knowledge of the subject, obtained inductive sparks by the aid of a resonant circuit and oscillatory discharges.—Yours, &c., J. A. FLEMING.

University College, London.

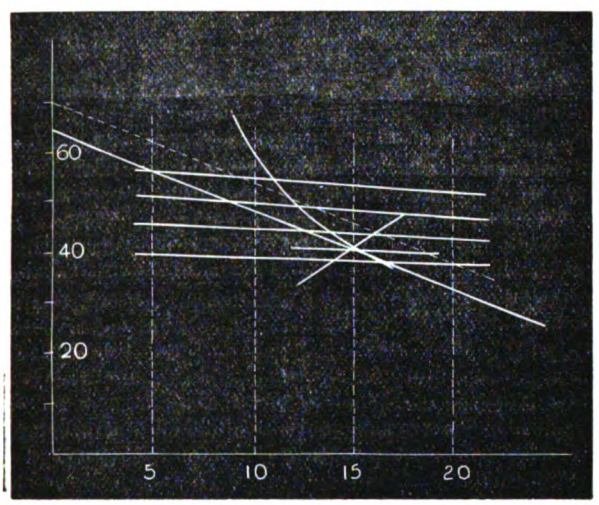
THE THEORY OF THE ARC LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the very interesting Paper on arc lamps, read by Prof. Silvanus P. Thompson at the Society of Arts meeting on the 6th inst., the author objected to arc lamps being regulated by the difference between the current and the E.M.F., and suggested that it would be better to regulate the arc so as to make the product of those quantities equal, and that the attempt at product regulation was essentially better than regulation by distance.

The Paper, however, does not attempt to show the electrical conditions under which the mechanism of an arc lamp acts. Nor do I remember to have seen this described. Had this matter been examined, it seems to me that the "equal watt" lamp suggested could have been shown to be no improvement on the "differential" lamps.

In the accompanying diagram let the horizontal distance represent amperes and the vertical volts as figured.



The four slightly inclined lines approximately represent at any point the relation between the volts and amperes, if the carbons be fixed successively at one-tenth, two-tenths, three-tenths, and four-tenths of an inch from each other, and the current increased from 5 to 20 amperes. Call these the carbon characteristics, or *carbon lines*.

Suppose the E.M.F. of the armature to be 65 volts, the current between the carbons 15 amperes, and the width of arc ·15, as illustrated on the diagram. The inclined line drawn from 65 volts may be called the *current line*, because it shows all the possible relations between the current and E.M.F.

The fall of E.M.F. as the current increases is, of course, due to resistance in the circuit. (In this case, say,

$$\frac{65-43}{15} = 1{\cdot}5 \text{ ohms}).$$

Since the carbon lines slightly fall it is impossible with an uniform E.M.F. to obtain a fixed arc. Moreover, an increase in the conductivity of the arc, such as by commencing to give off gas, would be represented, for the time, by making the carbon line more inclined. Hence, to make a steady arc, the decrease of E.M.F. with an increasing current between the carbon points due to any cause must be less than the decrease of E.M.F. with an increasing current due to the circuit resistance.

In the diagram the less the angle at which "current line" cuts the "carbon line," the less steady will be the arc, and the greater the angle the steadier the arc.

The position of the "current line" shows two things; first, the steadiness of the arc; second, when it cuts the successive "carbon lines" it shows the current when the arc is four-tenths, three-tenths, two-tenths, and one-tenth of an inch wide.

The mechanism of the arc lamps has nothing to do with these relations. The arc is regulated by the E.M.F. of the armature and the resistance of the circuit to certain definite relations of current and E.M.F. It is also rendered stable by the resistance of the circuit.

Suppose the lamp simply regulated by feeding when the current fell below 15 amperes. Then the vertical line at 15 amperes may be called the lamp "*feed*" *line*.

Or, suppose the lamp simply regulated by feeding when the E.M.F. fell below, say, 43 volts for an arc ·15 long and 15 amperes. Then the horizontal line at 43 volts is the lamp "*feed*" *line*.

So long as the E.M.F. of the dynamo was constant one lamp would regulate as well as the other.

Suppose there were no retractile feed, and that the E.M.F. varied and rose to 70 volts, this is illustrated by the dotted "current" line.

It is easy to see from the diagram, by noticing where the imaginary ·15 "carbon line" cuts the upper "current line," that the E.M.F. between the carbons would slightly decrease and the current rise to about 17 amperes. As the carbons burned away the second lamp, assumed above, would soon recommence regulating at about 16 amperes, and nearly the same length of arc. The first lamp would not regulate until the carbons had burned about ·25 apart.

Next, suppose the lamp had a differential feed and a retractile motion. In this lamp if the E.M.F. increase so also must the current. As the gear is always in the same position at the moment of feeding, the *feed-line* of this lamp is shown by the upward inclined line, which may be a curve, and its incline regulated by the designer or adjuster of the lamp. Judged by the diagram, an increase of 5 volts would cause the carbon to separate rather less than one-twentieth, and the current to increase to about 18 amperes, and very soon the lamp will be again feeding with about 17·5 amperes with ·2 arc. This is a much better regulation than before. If either of the first lamps had a retractile motion its "feed line" would be represented by an upward incline, and it would give as good regulation if running in parallel. The great advantage of the differential lamps is that they run so well in series.

In Prof. Silvanus P. Thompson's ideal equal watt lamp the "feed line" would be represented by the hyperbolic curve, and the effect of a rise of 5 volts would be to draw back the carbons about one-fifth, making an arc three-tenths of an inch long, with about 13 amperes and 50 volts.

Which would be most agreeable, this long purple arc with a tendency to flame or the brightened but steady arc of the differential lamp? Hence it may be concluded that with a small variation of E.M.F. the disparaged "differential" lamp would at least do as well as the equal watt lamp, and with a considerable variation of E.M.F. it would do much better.

The illustrative diagram here given does not pretend to give precise results, but merely represents a rough average of discordant experiments, and illustrates the average tendency rather than the precise results.—Yours, &c., WILSON HARTNELL.

March 18, 1889.

ON THE DESIGNING OF CONTINUOUS-CURRENT DYNAMO MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am much obliged to Mr. Geipel for kindly drawing attention to the omission of a 2 in one of the formulæ and examples contained in my Paper on the above subject. Regarding his remarks about the alteration of magnetic resistance with different degrees of magnetisation, and the consequent variation of Kapp's Coefficient 2, you will observe when you get the next number of the monthly *Transactions* of the Institution of Engineers and Shipbuilders, that I explained these points prior to the discussion upon my Paper.

The Paper did not embrace the calculations for magnetisation curves, but simply considered the case of dynamo working at full power, where the values given and found fitted in very well with Kapp's Constants.—Yours, &c.,

ANDREW JAMIESON.

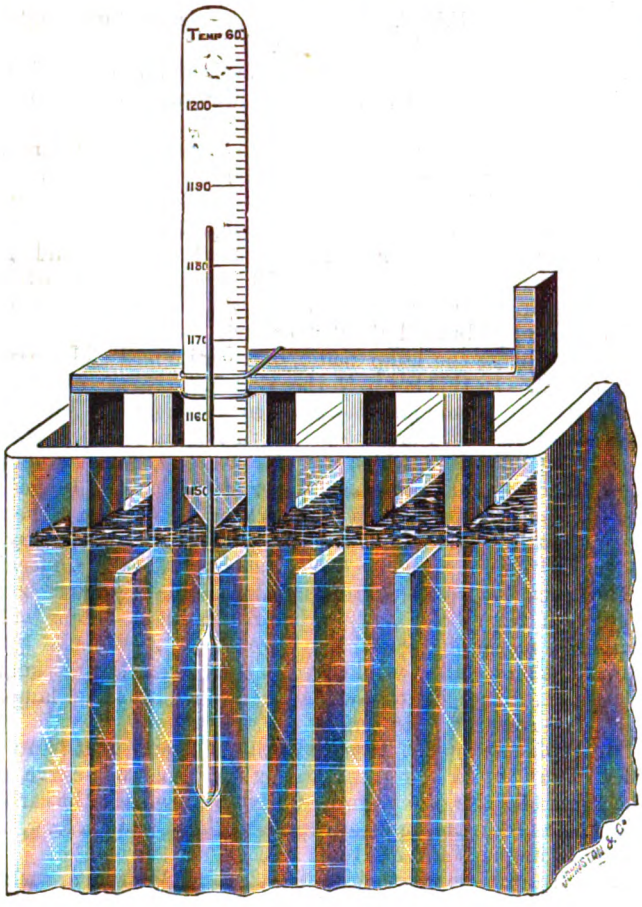
THE HOLDEN HYDROMETER.

This hydrometer, which has been designed by Captain Holden, R.A., specially for secondary batteries, and has been in use for the last year or so, consists of two parts, viz., hydrometer float and scale. In use the latter is clipped to the plates by an india rubber ring and then pushed down until the point at the lower end touches the liquid. The density is then read by the position of the top of the hydrometer stem on the scale (*see* Fig.) The scale is very open, one degree being represented by a tenth or even a quarter of an inch. It is made in glass and ebonite, the former



The Holden Hydrometer.

being the more accurate while the latter is the less fragile. These hydrometers are made by the well-known barometer maker, Mr. Pilkin.

COMPANIES' MEETINGS & REPORTS.

Brazilian Submarine Telegraph Company (Limited).

An extraordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Tuesday, for the purpose of ratifying an agreement, dated the 8th inst., made between this Company and the Western and Brazilian Telegraph Company (Limited), with respect to the working of the lines of the two Companies and the division of the traffic receipts thereof. Viscount Monck presided.

The SECRETARY (Mr. Richard Collett) having read the notice convening the meeting,

The CHAIRMAN said that he remembered once, at a time of political crisis in the House of Commons, when considerable communication was going on between the heads of the different parties, Mr. Gladstone was subjected to a severe cross-examination as to the state of affairs. He prefaced his answer by saying that he found it rather difficult to carry on delicate communications in a glass beehive. It seemed to him that the position of a director of a company was of the same character. The directors were constantly asked in meetings like the present to give an account with great minuteness of the manner in which their transactions were carried on. Although, however, there might be nothing whatever that it was desirable to conceal on its own account, yet he put it to them, as men of business, whether any private individual would carry on his transactions under these conditions. No one liked to admit that he was losing by his business, and if they showed great gains it might have the effect—particularly in a business like theirs—of attracting competition, which would very likely interfere with their future profits. The Directors could not communicate the nature of their transactions to the shareholders without at the same time taking the public into their confidence, and that, without their having anything to say which was in itself at all disagreeable, might be very injurious to the interests of the shareholders. The only way in which he could conceive that that difficulty might be got over was by an extension of confidence on the part of the shareholders to the Directors. For sixteen years the Board had managed the affairs of the Company, and he ventured to say that the shareholders would not disagree from the statement that the Directors' management had not been, on the whole, unsuccessful. He therefore asked them to accept the assurance of the Directors and himself that the engagement which they had entered into with the Western and Brazilian Company was for the benefit of their respective concerns. The Western and Brazilian Company was started at the same time as their own Company, and from the beginning up to now they had been working in intimate relations with that Company. Perhaps the shareholders were also aware that the concession of the Brazilian Submarine Company from the Brazilian Government, which gave them at present a monopoly of the traffic to Brazil, would terminate in four years from next June.

The SOLICITOR (Mr. Burt): The monopoly right.

The CHAIRMAN: Yes. The termination of that concession would not prevent the Company from working to Brazil, but it would terminate their monopoly right to work to Brazil. For some reason, however—he did not know how the fact originated—the concession of the Western and Brazilian Company lasted for 40 years longer, so that that Company had the monopoly of their rights for that period longer than the Brazilian Submarine Company had theirs. Hitherto they had worked with the Western and Brazilian Company on the plan of taking a certain proportion of the receipts of that Company, and giving the latter a certain proportion of the Brazilian Submarine Company's receipts; but it was now wanted to make the connection permanent and more intimate. Their future relations would, under the proposed agreement, be regulated by the receipts being paid into a joint purse, each Company taking a certain proportion of the receipts, the proportions being 54 to the Brazilian Submarine Company, and 46 to the Western and Brazilian Company. The agreement embodied several articles for giving thorough effect to that arrangement, and it

contained one article to which he attached great importance—an article enabling the Brazilian Government to come into the arrangement if they should wish to do so on terms to be agreed upon. If that article could be carried into effect, it would undoubtedly place both Companies in a very advantageous position; but the Brazilian Government had not as yet shown much wish to give its adhesion to that article. They must hope that the Government would be better advised in the future, and meantime the agreement would place the two Companies on a very satisfactory basis for the future conduct of their trade. The Western and Brazilian Company, as hitherto, would be collectors for the Brazilian Submarine Company at the other end of the line, and would be bound to give them every message sent to them to convey to Europe; and the Brazilian Submarine Company would act in a similar way with respect to the other Company, and would hand to that Company the messages received by them for Brazil.

The SOLICITOR (at the request of the Chairman) then read the agreement, which set out—in addition to the facts mentioned by the Chairman—that new cables would be laid by the Western and Brazilian Company as soon as they could, but within two years of the date of the agreement, from Pernambuco to Bahia, from Bahia to Rio de Janeiro, and between Rio Grande do Sul and Monte Video. It was understood that the agreement was simply for a joint working arrangement and was not an amalgamation; and the agreement would take effect as from the 1st of March, 1889.

The CHAIRMAN then moved the following resolution :—

"*That the agreement dated March 8, 1889, and made between this Company of the one part and the Western and Brazilian Telegraph Company (Limited) of the other part, with respect to the working of the lines of the two Companies and the division of the traffic receipts thereof (which agreement has been read to this meeting), be and the same is hereby ratified.*"

Sir JAMES ANDERSON said he had great pleasure in seconding the motion. It had taken several years to bring matters to the present position. He was sure they would do well to approve the agreement.

The CHAIRMAN put the resolution, which was at once carried unanimously, without discussion.

On the motion of Mr. J. G. GRIFFITHS, seconded by Capt. BLAKEY, a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN acknowledged the compliment, and the proceedings then terminated.

The Western Counties and South Wales Telephone Company (Limited).

Report of the directors for the year ended 31st December, 1888, to be presented to the shareholders at the fourth annual ordinary general meeting to be held at the Grand Hotel, Broad Street, Bristol, on the 27th inst at two o'clock :—

Capital Expenditure.—The capital expenditure for the year ended the 31st December, 1888, has been £27,885. 3s. 6d., making a total of £113,176. 0s. 2d. to date.

Revenue.—The gross revenue of the company for the year 1888 was £32,206. 9s. 7d., against £23,597. 10s. 5d. for the year ended 31st December, 1887. The amount of income carried forward to next year's revenue, as representing sums received in advance for periods extending beyond 31st December, 1888, is £10,403. 7s. 1d., against £8,043. 14s. 1d. in previous year's balance-sheet.

Working Expenses.—The working expenses for the year 1888, have been £8,337. 15s. 3d., against £6,693. 8s. 3d. for the year ended 31st December, 1887.

Dividend.—Balance of Net Revenue Account	£8,798	12	8
Dividend of 6 per cent. on the paid-up Preference Share Capital for the year ended 31st December, 1888	5,945	14	3
Balance for appropriation, as per statement at end of accounts	£2,852	18	5

Ordinary Capital.—The Directors recommend a dividend of half per cent. per annum on the Ordinary Share Capital, amounting to £1,405. 19s. 9d., and that the sum of £200 be placed to the Special Reserve Fund, carrying forward £1,246. 18s. 8d. to next year.

Growth of Business.—It will be seen from the following figures that the growth of the business of the Company for the past year has been satisfactory; the number of subscribers to the Company's exchange system having considerably increased, while there has also been a good addition to the number of Private Line Renters. The subscribers to the various exchanges and the Private Line Renters on the 31st December, 1888, and on the 31st December, 1887 (including orders on hand), were as follows :—

	Exchange.	Private.	Total.
December 31st, 1888	2,054	556	2,610
December 31st, 1887	1,572	462	2,034
Increase in 1888	482	94	576

Mileage of Trunk and Renters' Wires—

Erected up to 31st December, 1888	3,109 miles
" " 31st December, 1887	2,140 "
Increase in 1888	969 "

Trunk Lines.—The company has increased its Trunk system, so that on thn 31st December, 1888, it had 283 miles of Trunk pole lines connecting towns with each other, carrying 1,387 miles of wire; against 224 miles of Pole lines, carrying 922 miles of wire, at the corresponding date in the previous year.

The Directors announce a further extension of business, and the report, which is full of useful details of the Company's existing and projected lines, announces that the Company have received numerous inquiries for a connection between the principal towns of their district and the metropolis, and negotiations are pending with the United Telephone Company for the construction of the line. It is also intended to connect Bournemouth, Southampton, and Portsmouth with London, *viâ* Winchester. The Directors further say that inquiries have also been received for connection with Birmingham, Manchester and Liverpool; and should circumstances warrant the expenditure, the Company will proceed to make the necessary arrangements.

Mr. Mark Whitwill and Commander D. M. Forsyth, retire by rotation, but are eligible for re-election. Messrs. Hudson Smith, Briggs and Co. retire, but are eligible for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 15th, 1889, amounted to £5,148.

MONTE VIDEO TELEPHONE COMPANY.—This company announces an interim dividend at the rate of 6 per cent. to December 31 last on their Preference shares, payable on and after the 25rd inst.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 15th, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,074.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts for the half-month ended March 15th, 1889, were £3,680, against £3,337 for the corresponding period last year.

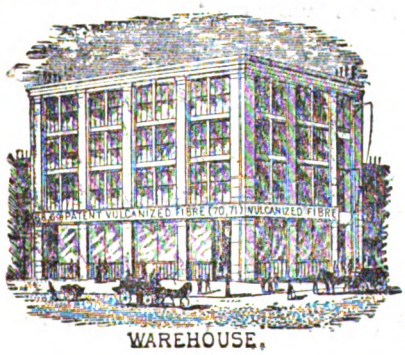
Messrs. F. Wiggins and Sons, the well-known mica merchants, of 10, Tower-hill, London, E., announce that, owing to increased business, they have taken additional premises at 102, Minories, which are in telephone communication with their old premises.

Messrs. Laing, Wharton and Down inform us that that portion of their business relating to the Thomson-Houston system of electric lighting has now been formed into a limited company, under the title of the Laing, Wharton and Down Construction Syndicate (Limited), with a capital of £40,000. None of the shares will, however, be offered to the public, as the whole of the issue, viz., £30,000, has been privately subscribed.

CHANGES OF ADDRESS.—We are informed that the offices, warehouse and show rooms of the General Electric Company (G. Binswanger and Co.) have been removed to 71, Queen Victoria-street, E.C.

———We are informed that the engineer's office of the Metropolitan Electric Supply Company is now at 4, Waterloo-place, S.W.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

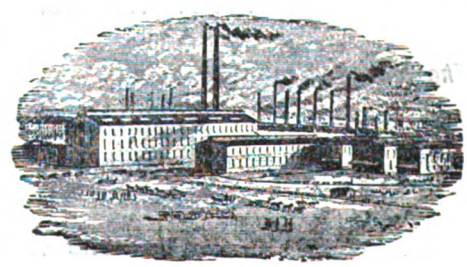
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 567.—Vol. XXII. FRIDAY, MARCH 29, 1889. Price Fourpence.

NOTES.

The discusssion on Prof. Forbes' Paper on Central Station Lighting, at the Institution of Electrical Engineers—which was concluded last week—has been on the whole of a disappointing character. From the importance and interest of the subject, and the general character and scope of the Paper, we had anticipated a discussion which might take rank as one of the most memorable of recent years; but this was very far from being the case. The majority of the speakers seemed to think it their duty, or their interest, to maintain that Prof. Forbes was wholly mistaken in supposing that English electricians had anything to learn from their Continental brethren. This may, perhaps, be patriotic, but we confess that to us it appears simply childish. Those who fancied themselves aggrieved may derive consolation from the reflection that Prof. Forbes distinctly implied that in not a few cases the lesson of how not to do it is the one that is chiefly impressed by a study of the detail of the Continental stations; and if he refrained from laying emphasis on these points, doubtless it was a sense of courtesy which restrained him. We mention this matter chiefly because we think it unfair and absurd that Prof. Forbes should be supposed to cherish an unreasoning admiration for everything that has been done abroad, or an equally unreasoning depreciation of what has been done at home. We fail to trace any such feeling in the Paper in question.

Perhaps the most important lesson of which Prof. Forbes has spoken is that of the absolute necessity for the use of feeders or of some equivalent means of equalising potential in all but the very smallest networks—a necessity which is common alike to direct and alternating systems. That this question has been unduly neglected in this country both in respect of theory and practice is certainly true. We are not aware of a single instance of the actual use of feeders in this country at the present time. It is, no doubt, true that as yet the majority of our central stations are upon so small a scale that the potential can be kept fairly constant without such devices; but it is nevertheless certain that already the Board of Trade standard of maximum variation is frequently exceeded. Probably before the year is over some appointments will have been made to the office of Electrical Inspectors, and then we shall doubtless hear more about this matter. Meanwhile, in planning new stations we trust that Prof. Forbes' recommendations will receive due consideration.

That the feeder method of regulation does not in itself constitute an ideal system will scarcely be disputed by anyone, and numerous efforts have in fact been made to obtain a more efficient and less costly mode of securing constancy of potential. Hitherto no practical success has been attained in this direction; but from our excellent contemporary the *Electrical World*, of New York, we now learn that at the new Edison station at Easton, Pa., a novel and successful method of regulation has been adopted, in which feeders are entirely dispensed with. Unfortunately no details have yet been made known, but our contemporary states that the device secures absolutely constant potential throughout the system.

This, however, is not the only attempt which has recently been made to improve upon the existing methods of regulation in the case of low-tension distribution. At a recent meeting of the Berlin Elektrotechnische Verein, M. Lahmeyer read a Paper in which he described an ingenious potential regulator devised by himself, and used with much success by his firm in extending the operations of their central station at Rostock. M. Lahmeyer employs a compound-wound dynamo, which he inserts in the compensating circuit. The armature and thick wire coils are in series with the lamps and the shunt coils are taken off the main circuit of the central station; the two coils are wound in opposition, and are so arranged that when the compensating circuit is at full load the series and shunt-windings exactly balance. Below full load the shunt coils predominate and the E.M.F. of the compensating dynamo is counter to that of the main circuit; above full load the direction of magnetisation is reversed by the predominance of the series coils, and the auxiliary E.M.F. assists the main E.M.F. M. Lahmeyer also employs a simple series-wound machine, the E.M.F. of which always assists that of the main circuit; then as the fall of potential in the feeder is proportional to the current, and as the E.M.F. of the dynamo is within certain limits also proportional to the current, it follows that the E.M.F. generated by the auxiliary machine can be made to exactly compensate for the fall of potential. It will thus be seen that a wide variation of load is attainable without the difference of potential at the lamp terminals being affected. It is obvious that the field-magnets of the compensating dynamos must never anything like approach saturation, and we gather that they are made with an exceptionally large cross-section.

The chief objection which the practical electrician will doubtless urge against this method of regulation is the multi-

Digitized by Google

plicity of dynamos it necessitates. We think, however, that this drawback can be made too much of. Any system of regulation whatsoever means complication, and while in the Lahmeyer system we have indeed additional dynamos, we effect a saving in copper, attain a smooth automatic working, and lessen the duties of the attendants at the Central Station. If modern steam engines, fitted with modern governors, and modern constant-potential dynamos were employed, the only concern of the engineer in charge would be to maintain a good head of steam. There would be no necessity to keep a constant watch on the voltmeter, and to make perpetual alterations in the resistance of the feeders.

At the meeting of the Electrical Section of the London Chamber of Commerce held yesterday (Thursday) afternoon the attendance was rather large, and amusement was caused by the discovery of the fact that the Chairman had intended to hold a committee meeting, and that the notice calling a meeting of the Section had been issued under a misapprehension. It was only last week that we referred to the desirability of holding a sectional meeting, and we do not think that any harm was done by the abandonment of the committee meeting, especially since the Section set to work upon the very same agenda paper. The first question discussed was the formation of a committee to consult with the Committee of the Electrical Engineers on the question of an electrical standardising laboratory. On this committee the following gentlemen were appointed:—The Earl of Crawford, Major Flood-Page, Messrs. Garcke, Goolden, Pell, Swinburne and Wharton. On the question of Railway Rates, the Secretary announced that the Board of Trade proposed to hear the objections raised by each trade separately. After that they would arrange an informal meeting between the Railway Companies and the representatives of the trades, at which probably some points might be amicably settled. Finally, the Board would adjudicate upon the outstanding differences. On this important committee Messrs. Allbright, Garcke and Goolden were elected to serve, with full power to act or to co-operate with other Committees of the Chamber. It was also decided to appoint the whole of the General Committee, with power to add to their number, as a Vigilance Committee, "to watch the proceedings of the Board of Trade, Local Authorities, and other bodies in so far as they affect the Electrical Industry." Considering that the Board of Trade inquiry commences on Wednesday next, this Committee will have some work cut out for it at once.

The extent to which the coding of cablegrams has been carried is strikingly illustrated by a statement made at the Direct Spanish Telegraph Company's general meeting on Monday last. The Chairman informed the shareholders of this company that although they had carried 2,000 more messages in the last three months than in the corresponding period of the previous year they had earned less money; the total number of words transmitted being greatly diminished, notwithstanding the large increase in the number of telegrams. In point of fact there is going on a steady decrease in the average length of messages over all the great cables of the world, and in many cases the process results in a dead loss to the companies. The question is becoming a serious one for them, and hopes are beginning to be entertained that some remedy may be submitted for discussion at the next Telegraph Conference.

With regard to the transfer of the Submarine Telegraph Company's cables to State control, upon which we have commented at length in our leading columns this week, we may congratulate the shareholders on having given their directors a free hand to make the best bargain they can rather than having at once rejected or accepted the offer submitted to them. A little delay will do no harm, and may probably demonstrate even to the French Government that cables which are capable of earning their purchase-money in the course of twelve months are well worth having at that price. What is proposed at present is equivalent to only six months' purchase, and is from every point of view a harsh and unjustifiable attempt to take advantage of the Company's defenceless position.

Mr. Langdon-Davies' "phonopore"—the name is not a happy one—was first heard of some two years ago, when a few experiments were made upon the telegraph line of the South-Eastern Railway. At that time the apparatus had scarcely emerged from the laboratory stage, and although the experiments fulfilled their immediate purpose, the invention has not been again brought into notice until within the last few days. Those, however, who were cognisant of the nature of Mr. Langdon-Davies' discovery—for that is the proper word—were convinced that it contained the elements not merely of a striking advance in multiplex telegraphy, but that it would also in all probability lead up to other scientific and practical uses scarcely as yet foreseen. During the last two years Mr. Langdon-Davies has been hard at work perfecting and developing the apparatus, and so far as regards its application to multiplex telegraphy he has now attained results which may be fitly described as of a highly remarkable character. Next week we hope to publish a fully illustrated description of the device and of its application to duplex and multiplex telegraphy as now being carried out on the Midland Railway Company's lines; but, meanwhile, those who are not acquainted with the principle of the phonopore will probably be interested in the following brief description of the instrument.

The "phonopore" itself consists of an induction coil having two separately insulated secondary wires wound side by side. It is, however, essentially different from an ordinary induction coil, in that there is no circuit through either of the secondary wires, each being terminated, so to speak "in the air." In reality the two secondary coils are situated towards one another like the plates of a condenser. Moreover, the open ends of the two coils are not side by side, one being at one end of the coil and the other at the other. It will thus be seen that the phonopore possesses no conductive electric circuit, but that at the same time its two coils possess coefficients of self and mutual induction combined with static capacity. In what manner this little apparatus lends itself to the purposes of multiplex telegraphy we shall try to make clear next week. Meanwhile, we may remark that the exact nature of its action

Digitized by Google

affords very much food for reflection, and will in all probability give rise to a good deal of discussion. As to the mathematical theory, it is no doubt calculated to rejoice the soul of a THOMSON or a HEAVISIDE; but ordinary people may be excused if they are contented with an approximate idea of the physical character of the action. We are glad to learn that there is a considerable probability that Mr. LANGDON-DAVIES will read a Paper on the subject before the Institution of Electrical Engineers some time during the present year.

MR. WEBSTER'S proposals for the electrolytic treatment of sewage upon a wholesale scale were of so novel and, indeed, startling a character, that it is scarcely surprising if a good deal of scepticism was at first evinced in electrical circles. On Wednesday last, however, we spent some hours at Crossness, where we witnessed experiments both on a laboratory scale and also in the works erected by Mr. WEBSTER, which are capable of dealing with a million gallons of sewage per diem. In another column will be found a full description of these experiments, and we need only add that no one having witnessed them could feel the slightest doubt as to the efficacy of the process. On the other hand, every practical man will at once want to know something about the cost. The question is, however, much more easily asked than answered. The actual working expenses on the small scale now running at Crossness amount to about 13s. per million gallons, and at this price the effluent is delivered in a condition of purity which Sir HENRY ROSCOE considers quite unnecessarily high. But the actual cost of the process in any given case depends on several different factors, such as the normal "richness" of the sewage, the cost of iron and coal, and the degree of purification demanded. Moreover, in comparing it with the cost of any chemical process at present in use, it is desirable to ascertain whether the latter process, as carried out, is effectual. It is certain that in many cases, owing to the comparatively small quantities of chemicals employed, the treatment is very nearly ineffective. We are therefore inclined to take a very hopeful view of the future of this new and important branch of electro-technics. We may add that the total sewage of London amounts to 78 million gallons per day, which at the above rate for working cost amounts to nearly £19,000 per annum. The actual amount now expended for chemicals is very difficult to get at, but we believe it to be far in excess of the above figure.

THE Paris International Exhibition will open its doors in less than six weeks from the present time, and, in spite of the recent inundations, we have good reason to believe that, so far as the electric lighting is concerned, all the arrangements will be completed in good time. It seems probable also that the lighting of the Grand Boulevards and of the Place de l'Opera, for which the Municipality recently voted the funds, will not suffer much delay. On the other hand, it is now scarcely possible that the extensive concessions for the public distribution of electricity which were granted in December last will be sufficiently advanced to make any noteworthy display.

AT the moment of going to press we learn, with sincere regret, that Mr. C. H. B. PATEY, C.B., Secretary for Postal Telegraphs, G.P.O., died yesterday (Thursday), at 5 p.m., of congestion of the lungs.

The Elieson Sale.—We have received from Messrs. Wheatley Kirk, Price and Goulty the catalogue of this sale, but defer our remarks thereon to our next issue.

The Board of Trade Inquiry.—It was resolved at the last meeting of the St. Martin's-in-the-Fields Vestry that the clerk should appear at the Board of Trade inquiry on behalf of the Vestry.

Cable to Morocco.—Advices from Tangier report that the Sultan of Morocco has returned a satisfactory reply to the demands of the British Government. The cable is to be repaired without hindrance when necessary.

Lead-Covered Cables.—Writing on this subject Mr. Thomas Connolly says: "From long practical experience and from information received I am prepared to believe all that Mr. Preece asserts in regard to the life of lead-covered cables."

Telegraphic Communication with Bermuda.—In the House of Commons on the 21st inst., in reply to Sir Edward Watkin, the Postmaster-General stated that the Government had decided to lay a cable between Halifax and Bermuda.

United Telephone Company v. New Telephone Company.—We understand that a writ has been served upon the New Telephone Company by the United Telephone Company, and that the case may be expected shortly to come before the Court.

Alternate Cable Route to South Africa.—The Telegraph Construction and Maintenance Company's s.s. "Scotia," with the cable on board for the southern sections of the alternate cable *vid* the West Coast of Africa to the Cape of Good Hope, arrived some days ago at Cape Town.

Societe Internationale des Electriciens—The annual meeting of this society will take place on Wednesday next, when the Comité d'Administration for this year will be elected. The proposed president is Colonel H. Sebert, the vice-presidents being MM. Cornu, Hippolyte Fontaine and Raymond.

Conference on International Patent Law.—A committee appointed by Lord Salisbury is sitting at the House of Commons to consider the action of the British Delegates at the forthcoming Conference at Madrid, which is to settle a new International Convention with regard to patents. Mr. Shipton was the chief witness examined.

Instruments for the Measurement of Radiant Heat.—Mr. Vernon Boys is now delivering an interesting course of Cantor Lectures before the Society of Arts on this subject. The lecture on Monday next will be of special interest to electricians, as it will treat of thermo-piles, d'Arsonval's thermo-galvanometer, and other electrical instruments.

Royal Meteorological Society's Exhibition.—The annual exhibition of this society was held at the rooms of the Institution of Civil Engineers last week. The exhibition was chiefly devoted to actinometers and solar radiation apparatus, but it also included an interesting collection of photographs of lightning. There did not, however, appear to be any special features disclosed in these particular photographs that had not already been observed.

Portraits of Cable Celebrities.—Messrs. W. H. Beynon, fine art publishers, of St. Alban's Lodge, Cheltenham, have just issued (for private circulation) two remarkably good portraits of Viscount Monk, chairman of the Anglo-American Telegraph Company, and of Mr. Thomas Fuller, managing director of the Brazilian Submarine Telegraph Company. These are companion pictures to those of Sir John Pender and Sir James Anderson, issued by the same firm.

Galway.—The Galway Harbour Commissioners have decided, by a majority of ten to five, to adopt the electric light for harbour purposes. The tender of the Galway Electric Company, to supply 1,000 candle-power arcs at £20 per annum, and incandescents, ranging from 16 candle-power to 100 candle-power, at prices ranging from £1. 19s. 6d. to £5. 10s., has

Digitized by Google

been accepted. The works of the Galway Electric Company are in close proximity to the docks, and the dynamos will be driven by water-power.

Printing by Electricity.—On Saturday evening last the *Star of the East* was printed at the office of the *East Anglian Times* entirely by electricity, current being obtained from storage cells at Messrs. Laurence, Paris and Scott's electrical work in Carr-street, and the dynamo usually employed in lighting the building being run as a motor. The experiment, we believe, is the first of the kind in the kingdom, and was entirely successful. The credit of the performance belongs to Messrs. Laurence, Paris and Scott, and to their Ipswich manager, Mr. Sisling.

St. Olave's District Board.—At a meeting of this Board last week, the question of electric lighting of the district was considered. The Clerk said he had made certain objections to the proposals of the London Electric Supply Corporation, and the company now suggested that the Board should give their assent subject to the Board of Trade considering the matter. The Board resolved to accord their sanction to the scheme of the London Electric Supply Corporation, subject to the forms of order issued by the Board of Trade after that authority had heard the objections.

Nottingham.—The special committee appointed by the Nottingham Town Council is now considering the application of the Nottingham Electric Light and Power Company for the concession of an electric lighting area. At present no report has been agreed to, but an intimation has been given to several electric lighting companies that the application in question has been made to the Council, and these companies have been asked whether they are disposed to make any offer, if so, on what terms; and, further, whether they will insist upon the forty-two years of the purchase clause contained in the Electric Lighting Act of last Session.

Taunton.—It is evident from the following extract from a local paper that the people of Taunton are more than satisfied with the lighting of their town:—"Far from being a failure in Taunton, up to the present time the electric light has been a brilliant success, and the ratepayers, we feel sure, would be very reluctant to part with it. The light has been steady, strong and reliable. The demand for it is extending, and the prevailing desire now is that the company may find themselves able to apply it to domestic purposes." Taunton has recently been visited by deputations from the Bedford and Chelmsford Town Councils for the purpose of inspecting the electric lighting arrangements.

The Society of Arts Motor Trials.—At the Society of Arts last Wednesday week Prof. Kennedy, F.R.S., read a Paper relating to the recent motor trials instituted by the Society, explaining their object and the methods adopted, in language suited to a non-technical audience. The thoroughness and trustworthiness of the trials were afterwards testified to by Sir F. Abel, C.B., and Mr. W. Anderson, M.I.C.E.; the Chairman, the Duke of Abercorn, then presenting the Society's gold medals to the following competing firms:—The British Gas Engine and Engineering Company for a 6 horse-power Atkinson "Cycle" gas engine; Messrs. Crossley Bros. (Limited), for a 9 horse-power "Otto" gas engine; Messrs. Dick, Kerr and Co., for an 8 horse-power "Griffin" gas engine; Messrs. Davey, Paxman and Co., for an 8 horse-power compound portable steam engine.

Chelmsford.—As reported in our last issue, the Chelmsford Town Council recently held a special meeting to consider the question of the public lighting of Chelmsford, and it was decided, amongst other things, to call a public meeting, and invite the opinion of the burgesses upon the matter. This meeting took place in the Corn Exchange on Tuesday evening last, and there was a large attendance. Mr. Councillor Whitmore moved "That this meeting is of opinion that the recommendation of the Lighting Committee be carried out, namely, that the Council be requested to accept the tender of Messrs. Crompton and Co. for the public lighting of the borough." Mr. Alderman Duffield, chairman of the Gas Company, said the Gas Company had sent in an amended tender, offering to light all the present lamps for the sum of £604, which was something like £100 in excess below the tender of Messrs. Crompton and Co., and asserted that the electric light for public purposes had proved almost an entire failure. Mr. Councillor Whitmore's proposition was then put and carried by a very large majority.

Proposed Spanish-Cuban Telegraph.—Barcelona advices report the existence of a movement in that city for the establishment of a cable between Spain and the Spanish Antilles. The commercial association in Barcelona known as the *Fomento de la Produccion Española* has petitioned the Colonial Minister in favour of the scheme, and it is stated that, provided the sanction of the Government can be obtained, local capitalists are prepared to form a company to carry the proposal into effect. It is pointed out that a direct cable not touching at any foreign port would be advantageous to the State, and its feasibility is urged upon the grounds that there is already a cable from Cadiz to the Canary Islands, a distance of 720 miles, and from Cienfuegos to Santiago in Cuba. It would only, therefore, be necessary to lay a cable from the Canary Isles to Porto Rico, a distance of 2,700 miles, and from Porto Rico to Santiago de Cuba, a distance of 100 miles.

Reading.—For some weeks past preparations have been made by Messrs. Laing, Wharton and Down, with the consent of the Corporation, for the installation of their electric lighting system in Reading for a month's trial, and a preliminary trial of the lights was recently made with considerable success. The central station is situate on what is known as the Island, in Duke-street. The engine-room plant is in duplicate throughout, and comprises two engines of 10 horse-power nominal, running at 380 revolutions per minute, with steam at 110lbs. Each engine drives direct a Thomson-Houston H type dynamo, running at 950 revolutions per minute, and capable of supplying eighteen 1,200 candle-power arc lamps on a five-mile circuit. The boiler is a Babcock and Wilcox 25 horse-power water tube boiler. Messrs. Laing, Wharton and Down are ready to supply thirty 1,200 candle-power arcs for street lighting at £22 per lamp per annum.

Telegraphic Charges to Austria.—According to the Vienna correspondent of the *Standard*, while the telegraphic charges between Germany and England are to be reduced after 1st of April, the rates between England and Austria are to be maintained at their old level. The reason assigned is that Germany refuses to allow Austro-English correspondence to profit by the new tariff. Ten words to England from Vienna cost at present two florins thirty kreutzers, while the charge to Germany is seventy kreutzers, and from Germany to England ninety kreutzers. Consequently a saving of seventy kreutzers, or thirty per cent. can be effected by telegraphing to Germany and thence to England, instead of direct. The fact is so injurious to trade between Austria and England, that the English Postmaster-General would do well to bring some pressure to bear upon the German Postal Administration, in which step he would be readily supported from the Austrian side.

Entertainment at the Edison and Swan Company's Factory, Ponder's End.—The second annual concert was held at the company's works, Ponder's End, on Wednesday evening, 27th inst. Nearly the whole of the *employés* availed themselves of the kind invitation of Major Flood Page (Secretary) and Mr. Gimingham (Resident Superintendent). A few tickets for friends had been issued, and the number present would probably be about 500. Before the concert commenced Major Flood Page addressed a few words of welcome couched in very appropriate terms. Regarding it from any standpoint, the entertainment was a complete success. A good programme was provided, the songs, &c., of the ladies and gentlemen who volunteered their services being much appreciated. Mrs. Gimingham and Miss Goater accompanied the singers. A sketch entitled "A Curious Dilemma" was very ably rendered by a few of the *employés*. The programmes were tastefully got up for the occasion, a striking and pleasing feature being a series of unique designs by Mr. Watson, bringing into prominence the company's manufactures, such as incandescent lamps, fittings and miners' safety lamps. The large room in which the company assembled was decorated with flags and lighted throughout with coloured electric lamps. A drop scene painted by Mr. Watson was very much admired. The whole of the arrangements were under the direction of Mr. Robson.

Telegraphic Communication with Johannesberg. — The following is extracted from the *Natal Mercury* of February 27th last:—"The need of activity is undoubtedly pressing in the case of the telegraphic service, which has again and again broken down of late under the weight of abnormal correspondence. No one could possibly foresee that Johannesburg would become the telegraphic focus of South Africa. Thither flock the messages of the speculating world. The Rand is for the moment the Mecca of the London Stock Exchange. It is not less the goal of every South African 'operator.' Facilities of communication with Johannesburg just now mean gain or loss—fortune or failure—to thousands and tens of thousands of persons. Priority of knowledge is a matter of transcendent concern to people who have thousands dependent upon the chances of a rise or fall in the share market. The deliberate cutting down of hundreds of yards of wire between Coldstream and Heidelberg shows to what lengths roguery will go. When we write, telegraphic communication with the Rand has been suspended for four days. Before this issue appears it may have been resumed, but no one can say what gains or what losses may not have occurred through this suspension. That the gains have been fraudulent in so far as they have accrued to those who planned and executed the breakage of the wire goes without saying; but many operators perfectly innocent of complicity in that crime will have benefited or suffered by the fact. It is so easy to bring about a stoppage of this sort that specially remedial measures are unavoidable."

Barnet.—At a recent meeting of the Barnet Local Board the subject of the position of the contractor for the electric lighting of the town, in view of the circular issued by the Board of Trade early last month, was under consideration. A report was read from the Lighting Committee, stating that they had discussed the terms of the Board of Trade circular, and had come to the conclusion that, in the face of this communication, the Board could not allow the streets to be interfered with by the electric light contractor until the statutory powers referred to therein had been obtained. At a meeting held on the 18th inst. the contractor attended before the committee and urged the importance to him of the transfer of his liability under the existing contract to the proposed company. The Committee, however, pointed out that after the receipt of the communication from the Board of Trade they could not recommend such a course to the Local Board until proper powers had been obtained by the contractor, as stipulated for in the contract. The report was adopted. At a subsequent stage of the proceedings letters were received from Mr. Joel's solicitors asking that the Board would join with the contractor in a memorial to the Board of Trade, praying them to waive the month's notice required for the special meeting of the Local Board to give their consent to an application to the Board of Trade. After some discussion it was resolved "That a reply embodying the facts of the case as now before the Local Board be sent to the Board of Trade, and that in the letter it should be shown that the Local Board are desirous of complying with its duties under the contract, and particularly with the rules of the Board of Trade," the Chairman remarking that in this way the Board could assist the contractor without committing themselves in any way.

The Tangiers Cable.—The following extracts from the *Times of Morocco*, of the 16th inst., will give some idea of the state of affairs at the Ports of Morocco:—"Some idea of the ridiculous scare which at present prevails in Morocco, raised by the refusal of the Customs Administrators at Tangiers to pass a length of wire required by the Eastern Telegraph Company to repair their line at this end may be gathered from the following extracts from letters received:—A Mogador correspondent states that 'A scare was raised on 1st March among the native population by the summoning in hot haste of the troops, both *gaïsh* and *âskar*, and their being told off to man the forts of the town and the two islands, other parties being dispatched to occupy the village of Decâbat, and patrol the beach on either side of the town, with orders, if they saw anything approaching from the sea, to fire without mercy.' All that could at first be gathered of the cause of this unwonted activity was that Shereefian orders had been received by the authorities to be 'on the look out.' Needless to say the wildest rumours were current among the more ignorant native, not a few rushing to the conclusion that there was to be an immediate war with the Christians, nation not specified. Others in mysterious whispers hoped the Sultan was in good health. Meanwhile the martial preparations went briskly on. Gunpowder was served out to the troops, and many were the rusty old guns unearthed and placed in the hands of boys who had never discharged a musket in their lives. An informal sort of parade was held by the *Kâ'id*, before whom these gallant, involuntary recruits were required, one after the other, to fire off their weapons. Those who bungled very badly 'ate stick.' All night long bullet-moulds were at work. On the 2nd inst. it leaked out that these measures were taken with the view of preventing a telegraphic cable being laid by some foreign company, and the arrival of the ss. 'Les Vosges,' with news from Tangier, confirmed this view of the matter." Another Mogador correspondent writes:—"The rumour spread that the Spaniards were coming; of course the Mellah was in a fearful state by Sunday; yesterday the story was that they were watching for someone coming to lay a cable. One of the soldiers' description of his orders are immensely amusing. When asked what he was doing on the battery wall he said, 'The Governor told me I was to look up and out to sea, and if I saw a great ball coming down from the skies towards the shore dragging after it a long wire, I was to fire at it.' It is evidently a telegraph scare, and probably only got up on account of that 30 miles of wire lying at Tangier now."

Electric Lighting in London.—The Board of Trade has addressed the following letter to the Earl of Rosebery as Chairman of the London County Council:—

"Board of Trade (Railway Department),
"London, S.W., 13th March, 1889.

"My Lord: I am desired by the President of the Board of Trade to inform your lordship that the question of Electric Lighting in the Metropolis is at present receiving the serious consideration of this Department. Thirteen applications for Provisional Orders, under the provisions of the Electric Lighting Acts, 1882 and 1888, in respect of areas within the metropolis, are now before the Board.

"In dealing with these applications the Board of Trade are at once confronted with two important questions of principle:—

"(1) What should be the extent and nature of the area to be granted?

"(2) Should, or should not, concurrent powers be granted to two or more companies within the same area?

"As regards the former, many considerations must be taken into account—*e.g.*, what is the financial position of the undertakers applying for statutory powers in any given area; how far any one company would be in a position satisfactorily to supply such an area, and in connection with this much would depend on what distance electrical energy for electric lighting purposes can be safely and conveniently furnished from a central station.

"As regards the latter question, on the one hand it appears to the Board of Trade to be highly desirable to avoid the grave inconvenience to which the public were subjected when there were competing gas companies supplying the same areas in the metropolis; and, further, in the case of electric lighting, that uncertainty exists whether mains can be satisfactorily laid in close proximity to each other. On the other hand, some of the Local Authorities in the Metropolis appear to be desirous to encourage competition, and are anxious to avoid the creation of a monopoly or quasi-monopoly for electric lighting by giving any company exclusive powers for any one area.

"Before deciding on the action to be taken on the applications at present before the Board of Trade, they propose to adopt their usual procedure, and to hold a local inquiry, of which full notice will be given, and at which all those interested can be heard; but they are anxious to take no definite step which may have important bearing on the future policy to be pursued with regard to Electric Lighting in the Metropolis without communicating in the fullest manner with the County Council of London.

"In this determination they are greatly influenced by the consideration that before long the jurisdiction which the Board of Trade now exercise in regard to electric lighting matters in the metropolis may be transferred to the County Council, and they would therefore be most unwilling to take any action which might hamper that body in dealing with the question in the future.

"With this view they propose, as soon as the report of the inquiry has been received, to forward it to your lordship for the information of the County Council, and I am, at the same time, to express a hope that this Board may then be favoured with any observations which the County Council might wish to offer upon this large and very important question.—I have, sir,

"The Earl of Rosebery." (Signed) "HENRY G. CALCRAFT.

NOTE ON THE BURSTING OF LEYDEN JARS.

BY DR. OLIVER LODGE.

The circumstances attending the electrical fracture of Leyden jars are of some interest. So far as my experience goes, they do not often burst by being merely overcharged to too high a potential—whether they ever do so I am not sure—but they burst at the instant of discharge by the recoil and oscillations set up in the discharging circuit. When this discharging circuit is a long one I should have expected their fracture to be more probable, were it not that they then readily overflow. A spark of an inch or less will easily make a jar spark over its edge if it be joined up to a suitable wire circuit, and this ease of overflow may perhaps save them from breaking.

With a short discharge circuit it may be possible to take sparks several inches long without their overflowing, and the question is whether they are then more liable to burst or not. In other words, are bursting and overflowing the same thing? Fortunately my jars, though they frequently overflow, scarcely ever burst, and accordingly my experience is too limited to be any use.

When I take very long sparks from jars I use two in series; their liability to overflow is then greatly diminished. This is no doubt the empirical reason of the pair of jars used in all forms of inductive machine.

Apropos of the bursting of jars I have permission from the writers of the two following letters to communicate them, and I also quote a statement by Franklin on the same subject:—

Answer by Dr. Franklin to a question put by Dr. Ingerhouse about 1777.

"By the circumstances that have appeared to me, in all the jars that I have seen perforated at the time of their explosion, I have imagined that the charge did not pass by those perforations. Several single jars that have broken while I was charging them have shown, besides the perforation in the body, a trace on both sides of the neck where the polish of the glass was taken off the breadth of a straw, which proved that great part at least of the charge, probably all, had passed over that trace. I was once present at the discharge of a battery containing thirty jars, of which eight were perforated and spoilt at the time of the discharge; yet the effect of the charge on the bodies upon which it was intended to operate did not appear to be diminished. Another time I was present when twelve out of twenty jars were broken at the time of the discharge, yet the effect of the charge which passed in the regular circuit was the same as it would have been if they had remained whole.

"Were those perforations an effect of the charge within the jar forcing itself through the glass to get at the outside, other difficulties would arise and demand explanation. 1. How it happens that in eight bottles, and in twelve, the strength to bear a strong charge should be so equal that no one of them would break before the rest, and thereby save his fellows, but all should burst at the same instant. 2. How it happens that they bear the force of the great charge till the instant that an easier means of discharge is offered them, which they make use of, and yet the fluid breaks through at the same time."—(Franklin's Works, Ed. Sparks, Vol. V., p. 462.)

The following two letters from Mr. Boys and from Mr. Bottomley tell their own tale:—

"It may interest you to hear how some of the large Polytechnic jars were broken here when we tried the 7ft. Wimshurst machine on them.

"On connecting up 1, 2, 3, or 4 'for quantity,' or in pairs 'for intensity,' with the machine, and charging until the brush discharge from the conductors was such as to make further increase of potential unattainable, and then causing the knobs to approach one another, there used to be a deafening explosion when they were from 12 to 16 inches apart, and almost every time one (or more?) jars were found shattered in one or more places. At each place of rupture the centre portions of the glass were white, being completely pulverised. This part would be a $\frac{1}{4}$ inch or so in diameter. Outside this radiating but irregular cracks spread in all directions over a space of two inches or so, and these cracks were joined by other cracks, more especially near the central powder.

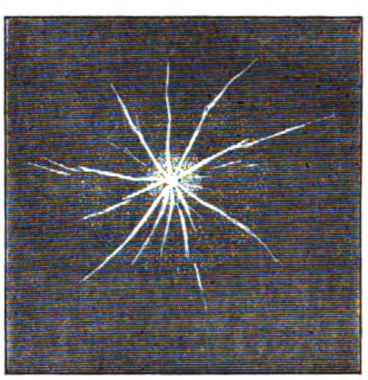
"This never happened during the charge, but only when the discharge was made at the knobs, and no doubt was largely due to electric oscillations breaking down the glass, which, while it could stand the steady pull one way, could not resist the see-saw. This may, for anything I know, have synchronised with the natural period of vibration of a bar of glass as long as the jar was thick where it broke.

"Finding that the proceedings seemed destructive of jars we left off.—Yours, &c., "C. V. Boys."

"13, University-gardens, Glasgow, March 22, 1889.

"The experiments, of which I wrote to you very hurriedly on February 6th, were made with a very large influence machine which my friend Sir Archibald Campbell, of Blythswood, has been building. I will tell you something more about the machine a little later; but meantime, in a very imperfect state—indeed almost at first trial—we got $\frac{1}{8}$ of a milliampere from it, as measured by decomposition of water. I have no doubt we can get a great deal more when we know the conditions necessary for keeping the potential of the parts which act as inductors from falling away as we draw off current.

"While the machine was giving a spark of $5\frac{1}{2}$ or 6 inches we sparked through two very large jars, 12in. high by 7in. in diameter, the glass about $\frac{1}{8}$ to $\frac{3}{16}$ thick, tinfoil 9in. up. On examining them it turned out in each case that the jar had been perforated in many places. In one jar there are six or seven holes, in the other I can count thirteen. The tinfoil was blown outward *on both sides* in each jar in six or seven places. It stood up from the glass in little protuberances bigger than a split pea, and in many cases, at any rate, the summit of the protuberance is pierced. On removing the tinfoil the glass showed unmistakable signs of many holes arranged in a line (in the case of the jar with the largest number of holes in two lines, one branching off from the other). The holes are about half an inch apart; the distances tolerably regular. There is in one of the jars one very heavily pulverised place and two in the other;—round spots about a quarter of an inch in diameter,



where the glass is a mass of white powder, in each case at one end of the line of holes and seemingly a starting place; and in the very centre of the most thoroughly pulverised spot there is a small clean round hole, through which I can put a wire one-hundredth of an inch in diameter right through, quite loosely and without rubbing on the sides of the hole. (I have not tried the largest wire possible as I do not want to disturb the glass powder just yet.) The remaining holes are small perforations, a crack joining them all, and round about each there is a small spot covered with metal driven off the tinfoil on to the glass.

"One of the sets of perforations is just round the upper edge of the tinfoil coatings. The other is round the bottom of the jar.

"I shall be greatly interested to see what you say about the matter, and when we break any more—which I doubt not will be soon—you shall hear of it.—Yours, &c., "J. T. Bottomley."

Note added by Mr. Boys.

The first of Mr. Bottomley's letter reminds me that the position of the holes in the glass was indicated by large blisters in the tinfoil and that in the centre of the white powder there was, as he describes, a clean hole. The glass in these jars was not, as far as I can remember, as much as $\frac{1}{8}$ inch in thickness at the places where they broke. C. V. B.

ELECTRIC LIGHTING AT THE ERECTION OF THE FORTH BRIDGE.

BY ALFRED E. MAYOR.

As the Forth Bridge is now approaching completion, a description of the lighting arrangements, which have in some measure facilitated its rapid progress, may be of some interest at this time. From the beginning operations have been carried

Digitized by Google

on continuously day and night, and among the earliest of the preliminaries was the arrangement of electric lighting installations. Messrs. Siemens Bros. secured the contracts for lighting the offices, machine shops, yards, and jetties on the south side of the river, while Messrs. Crompton and Company secured the smaller contracts on Inch Garvie and North Queensferry. During the foundation work electric lighting was extensively used, not only on the stagings and jetties but in the working chambers of the caissons, where they proved invaluable aids to the men, who were working under the most trying conditions in an atmosphere of from 30 to 45lbs per square inch pressure. Arc lamps of the ordinary Siemens differential type were used: they had triple carbons, and of course these were consumed with great rapidity, and had to be frequently renewed. The divers working on the exterior of the caissons used incandescent lamps with strong protecting glasses, and these within a limited radius proved of great service. On the completion of the foundations and commencement of the superstructure a complete re-arrangement of all the lighting plant became necessary to meet the widely different requirements.

The installations as remodelled and extended may be briefly described as follows:—On the south side of the river, for the lighting of the engineering shops and yards, which cover an area of 50 acres, there are three Siemens SD^9 dynamos, each supplying 120 amperes at 110 volts, one Crompton and one Siemens machine, each supplying 50 amperes at same E.M.F., and five Siemens SD^8 machines for series arc lighting, each with a current of 15 amperes and 300 volts; there is also a Crompton machine for the same purpose wound for 15 amperes at 1,200 volts. Horizontal high-pressure coupled engines, indicating 120 horse-power, by Messrs. Davy, Paxman and Co., of Colchester, drive seven of the above dynamos, and two smaller engines, indicating respectively 30 and 10 horse-power, drive separate incandescent lighting dynamos. At the Central Pier, on Inch Garvie, there are two Crompton-Burgin dynamos, each for six arcs in series, and two 60-light incandescent machines of same type. These are driven by a pair of Shanks Caledonian engines, and there is a separate arc lighting plant, with a dynamo by Crompton, wound for 15 amperes at 1,200 volts, and driven by coupled Gwynne engines. On the north side of the river there are two Crompton machines, each for 80 incandescent lamps, and two Burgin machines, each running 12 arcs in series. These are driven by a 60 horse-power horizontal engine, and there is a separate plant for 24 arcs, similar to that on Inch Garvie. Underground conductors had been extensively used in the South Installation: they consisted of cables insulated with gutta percha and jute, with a sheathing of steel wires and an external serving of jute and compound; after three years' use they had all become more or less defective; they were, therefore, raised and removed to the erection, where their metallic covering is of great service, and when the demands of insulation are not so high, owing to the possibility of running them almost continuously on timber stagings. The machine shops are lit by Siemens differential lamps, principally arranged in parallel circuits of two lamps in each. Distributed among the cantilevers are 100 Crompton D D lamps. These have worked very satisfactorily under the most trying conditions.

The plan adopted for wiring the erection is as follows:—Overhead wires are run from the dynamo stations to distributing boxes at the different piers, and flexible cables tied to ropes are led from these to the lofty stagings on the structure. The lamps are suspended from light poles lashed to the girders, or are swung direct between guide wires from the arc bracings. Groups of lamps in series with other groups provided with automatic cut-outs and equivalent resistances to isolate the effects of accidents to the conductors. All the arrangements are necessarily extremely portable, as the stagings are constantly being shifted and re-arranged with the progress of the work. Although arc lighting has been extensively used at these works, and the advantages of its portability and cleanliness fully appreciated, its numerous disadvantages have also been amply demonstrated. In the engineering shops, in which the steel is prepared by numerous planing, drilling, and bending machines, the arcs have required the aid of myriads of hand lamps to render nightwork possible, and this notwithstanding the utmost attention which has been bestowed on the distribution of the light. In the erection of the steel the drawbacks of arc lighting have been even more conspicuous. Light temporary stagings, where even in daylight men must move about with much care, are in many cases lit up by an arc at some little distance off, but if even a small object is interposed between them and the minute source of light the men in their perilous positions are instantly thrown into extreme darkness by the sharp intense shadow. The works have therefore been a fitting place for the trial of rival means of illumination, and these have been forthcoming in considerable abundance, the most prominent among them being the Lucigen, which had one of its earliest and most extensive applications at the Forth Bridge. This light is probably familiar to most of the readers of *The Electrician*; it is obtained by forcing creosote oil or other heavy hydro-carbons, in the form of a spray, through a small nozzle by means of air pressure. The flame is about 3ft. long, and emits a light of great intensity and diffusive power. To maintain air pressure for each light of 2,500 candle-power only ·25 horse-power is necessary. When first introduced the oil—a bye-product in the manufacture of ammonia gas—was extremely cheap, and it seemed as if the new light was going to carry everything before it, but, although for many purposes it is unquestionably superior to the arc, it has not been completely successful, and more mature experience tends to considerably restrict its sphere. Its only unqualified advantage is its extreme diffusive power, and against this must be placed numerous defects which greatly modify its utility and convenience. Its alleged economy as compared with all other means of artificial illumination is quite fallacious. Creosote oil costs just now about 3d. per gallon undelivered, and, of course, the cost of transport is considerable; to maintain a light of 2,500 candle-power the lamp consumes from 2¼ to 3 gallons of oil per hour, according to the quality of the oil; considerable allowance must also be made for waste. A fair estimate of the cost per lamp of 2,500 candle-power is 9½d. to 10d. per hour. A small quantity of water in the oil instantly extinguishes the lamp, and one source of trouble with the system is the almost unavoidable presence of water in the oil; this water must be filtered away and carefully conducted to the sewers, as it is a product of intense annoyance. The light requires considerable attention, and is very unsatisfactory in a wind, as it is liable to go out, when the unconsumed oil is blown over the timber stagings, greatly increasing the risks of fire. Thus, notwithstanding the superior diffusive power of the Lucigen, the arc has maintained its position on all the elevated stagings, the Lucigen being extensively used, however, for the illumination of the yards and lower portions of the structure. It is, of course, misleading to estimate the power of such lights as the Lucigen by the ordinary photometric standard, as 1,000 candle-power from such incandescent lamps as those of the Sunbeam Company is much more effective than 2,500 candle-power from the Lucigen; this is doubtless owing to the perfect steadiness of the rays from the former. Sunbeam lamps are extensively used here, and are much preferred to either the arc or Lucigen; the additional cost is in many instances amply compensated by overwhelming advantages. There is, of course, a wide field for all classes of lights in a work of such magnitude, and the special adaptability of each has been as far as possible utilised. The spectacle presented on dark nights when the bridge is illuminated is a very striking one. The coronas of brilliant lights, from their lofty positions on the great structure, cast beautiful reflections into the water, and the massive overhanging columns and girders look most imposing when they are seen out of the darkness. It is expected that the last rivet will be closed in the autumn of this year, and already the electrical installations are being dismantled and prepared for the market. The dynamos have worked most satisfactorily throughout, and when it is remembered that these machines are of an early pattern, and have passed through rather a trying ordeal, the fact that they are now practically as good as new reflects the highest credit on their makers, Messrs. Siemens and Crompton.

Office Lighting.—The electric light is being put into the offices of Messrs. Rothschild in New-court, London, E.C.

MR. WEBSTER'S ELECTROLYTIC METHOD OF SEWAGE PURIFICATION.

The problem involved in the disposal of the sewage of our large towns is one not only of the utmost importance, but also of increasing magnitude and complexity; and, moreover, the conditions under which it must be dealt with vary greatly in different localities. So long ago as the year 1762 proposals were made for the artificial purification of sewage before discharging into running water, and since that time innumerable inventors have attempted the solution of the problem; but though more than one chemical process is to be found in operation, it is an admitted fact that hitherto no very substantial success has been attained.

The electrolytic process was first suggested by Mr. W. Webster some two years ago, and it is only fair to state that at that time he already possessed an adequate knowledge of the chemical methods hitherto proposed, and, moreover, he had had exceptional opportunities for observing the actual operation of these processes. In the autumn of last year Mr. Webster read a Paper upon the subject before the Society of Municipal and Sanitary Engineers, which appeared in *The Electrician* of September 7th, 1888, p. 558. Many of our readers will, therefore, be already acquainted with the main features of the electrolytic process. The actual operation is simplicity itself, although the electrolytic and chemical reactions are undoubtedly somewhat complicated; in fact, although only one operation is performed, there are really two results, one mechanical and the other chemical, as we shall presently explain. On Wednesday last, when the representatives of the technical journals visited the Outfall Works of the Metropolitan Sewerage System at Crossness, where Mr. Webster has now had an experimental plant in operation for the last nine months, we first witnessed some laboratory experiments upon a small scale designed to show the principle of the method. The colour, density, and constitution of the London sewage varies from hour to hour in a most extraordinary manner, but the first sample to be dealt with was of a light yellow colour, looking something like weak tea with a little milk in it; but so far as could be seen it contained very little solid matter in mechanical suspension. This having been poured into a test jar, a current was passed through it between a pair of iron electrodes, with about 6 volts E.M.F. An extremely rapid effect was produced. In less than two minutes the jar was seen to be filled with a flocculent precipitate which was gradually carried upwards by the bubbles of liberated hydrogen. After about three minutes the electrodes were withdrawn, and the precipitate left to collect at the top. In actual practice, after the effluent has passed into the settling tank the precipitate in the course of about two hours loses the whole of the entangled hydrogen; it then sinks to the bottom of the tank. The sludge thus formed is similar to that produced by the chemical processes now in vogue, except that the electrical method possesses the obvious advantage that the total quantity of material has not been increased by the addition of chemicals.

This removal of the precipitated solids, although it is the only effect visible to the eye, does not constitute the whole of the operation, nor even its most important part. There is also a chemical action upon the organic matters in solution, the exact nature of which is not wholly understood. It has long been known, however, that many of the ferrous salts, and the green ferrous oxide in particular, possess the property of acting upon or combining with organic matter in solution, although the chemical formula cannot at present be written down. Mr. Webster is inclined to think that in this instance the first step in the process consists in the formation of a hypochlorite of iron. All sewage, particularly in the absence of rainfall, is rich in chlorides, and this fact, it may be remarked in passing, is of advantage in increasing the electrical conductivity of the fluid. In any case, it is a fact that a certain quantity of free chlorine is liberated at one pole (which, of course, itself acts as a deodoriser and disinfectant), and the iron is ultimately converted into the form of the green (ferrous) oxide.

After the first experiment several samples of sewage, one of which was almost black in colour, were treated in the same way, and the flocculent precipitate was in every case produced with great rapidity. It may be added that the process must not be carried too far, otherwise the alkalinity of the effluent is increased to such an extent as to lead to secondary decomposition and the possible formation of sludge in the bed of the river. The consumption of iron has been found to be about two grains per gallon, but this is a quantity which depends upon the extent to which the purification is desired to be carried.

The following notes, describing the actual details of the process as now being carried out at Crossness, have been kindly furnished us by Mr. Webster.

"Since writing my former notes on the above question I have carried out a long and exhaustive series of experiments at my experimental works at Crossness, which have proved beyond doubt that I can produce on a commercial scale results at least equal to those obtained in the laboratory, and probably better. The mode of treatment adopted is the same, with the exception that for the slight

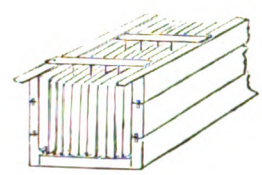

FIG. 1.—Detail of Shoot with Iron Electrodes.

motion of the electrodes, which was found necessary to bring the sewage into intimate contact with the plates, a movement of the liquid to be treated is substituted, the sewage being acted upon as it passes through the electrolytic channels leading from the sewer to the reservoirs or settling tanks.

"Starting with the engine shed, the engines, of an old type, made some 25 years ago, are each 20 horse-power nominal. By the arrangement of gear, one engine only is used at any one time, both for pumping and for driving the dynamo. The dynamo is an Edison-Hopkinson, capable of developing an energy of 43 horse-power. From the dynamo the leads run through resistance frames, by means of which the amount of current can be regulated without varying the speed of the engine. These are then connected with the iron electrodes in both the precipitating tanks and the shoot. The precipitating tanks are used for taking experimental measurements, so as to discover the best mode of arranging the electrodes, hereinafter called plates, made of cast iron, run direct from blast furnaces. Owing to want of space, I found it desirable to fit the shoot (*see* Fig. 1) with wrought-iron plates, which, of course, are

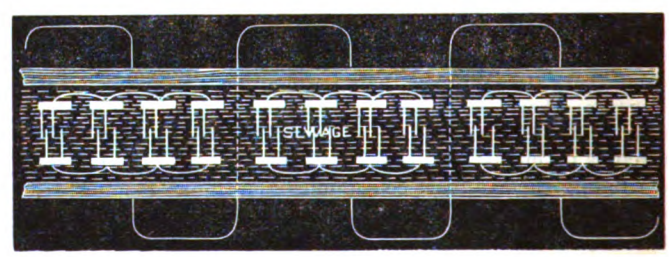

FIG. 2.

more convenient for experimental work, as they are thinner and weigh less than if made of cast iron. The shoot is of wood; but in any permanent work it would be built of bricks, concrete, or iron, and the bottom would be lined with asphalte or other suitable material.

"The sewage is discharged into the shoot from the pump connected with the main sewer. In travelling along the shoot every particle of the sewage comes in contact with the plates, and finally the whole is received into one or other of the settling tanks. All the plates in each section are connected in parallel, and the sections can be connected either in parallel or in series (*see* Fig. 2), as may be most convenient. I find it best in this instance to run them arranged as six sections in series, as, owing to the low tension of the dynamo, it is inconvenient to split them up into a greater number of sections. My experiments prove that with 27 horse-power it is possible to treat one million gallons of sewage in 24 hours. With this statement I must couple the remark that the figures relate to average London sewage.

"As to the cost of the engine power, I need hardly state that the newest type of engines suitable for driving dynamos may be taken to consume two pounds of coal per horse-power hour, and accord-

Digitized by Google

ing to the price of the coal will be the working cost. The experiments carried out with reference to the amount of iron consumed by this process tend to prove that the consumption in continuous working should not be more than two grains per gallon. Here again the cost entirely depends upon the position of the works, or more properly speaking, the district in which the works are situated. The prices in the pig iron market are so well known that I need not enlarge on this point. The plates are one inch thick, and if used in sufficient numbers would last for many years when once fixed. For instance, I will take a town with a flow of ten million gallons of sewage per day, corresponding to a population of 330,000, at 30 gallons per head. To treat this amount of sewage, the consumption of iron should not exceed 364 tons per annum, and the steam plant required represents about 8 horse-power per 10,000 inhabitants.

"It will be seen that the above plant is practically in lieu of the mixing tanks, machinery, and chemicals employed in chemical processes for the treatment of sewage, and if such electrical plant is designed to meet the peculiar requirements of any particular district, it must, in my opinion, cost less and have a greater efficiency than any other process known, for not only does this electrical method precipitate the matters in suspension, but it also removes organic matter in solution, and forms a precipitating and disinfecting process in one operation.

"The appended analyses of sewage and effluents show the reduction of both suspended and soluble matters by means of one treatment and also at the smallest possible cost."

ANALYSES OF EXPERIMENTS, 1888-9.

Parts per 100,000.

—	Appearance.	Odour.	Nitrogen as		Chlorine as Chlorides.	Oxygen required to oxydise organic matter.	Suspended matters.
			Free Ammonia.	Albumenoid matter.			
Average of 20 Analyses	Raw Sewage, very turbid & opalescent	Slight	4·34	0·5	21·64	1·24	33·35
	Effluent, clear	None	3·22	0·2	18·62	0·52	1·56

Time of settlement one hour in open reservoirs.

We may add, in conclusion, that the Edison-Hopkinson dynamo is a fine machine, built for the purpose by Mather and Platt, and capable of yielding about 1,600 amperes and 25 volts at 350 revolutions. The current density employed in the shoot is about 1 ampere per 11 square feet of surface, the total current being about 500 amperes. The sewage occupies about 10 minutes in traversing the full length of the shoot, which is about 400 feet in length. The total quantity of electricity employed is at the rate of ·25 ampere-hours per gallon of sewage, the E.M.F. across the plates being 2·5 volts. The details of the electrical arrangements have been carried out with considerable skill by Mr. O. March.

THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 23rd inst., a note was read by Prof. J. V. JONES on

"The Use of Lessajou's Figures for Determining Speed of Rotation; and on the Direct Determination of the Vibration Period of a Reed or Tuning Fork by Means of a Morse Receiver."

In the measurement of electrical resistance in absolute measure by the British Association method, or by that of Lorenz, it is necessary to be able to determine with great accuracy the speed of rotation of the revolving coil or disc at the moment that the galvanometer readings are taken. It was in connection with a measurement of resistance in absolute measure by Lorenz's method that the author devised the method described in the present communication. The method consists in obtaining, by means of Lissajou's figures, an equality between the period of rotation and the oscillation period of a reed electrically maintained in vibration. In one end of the axle of the revolving apparatus is placed somewhat excentrically a pin which fits accurately into a hole in a rod having one end free, while the other end is constrained to move only in the direction of the length of the rod.

Fig. 1 shows the application of the method to determine the speed of rotation of a Lorenz disc. M M M is the axle about which the disc rotates. The dotted circle B represents the excentric pin, which fits into a hole in the rod S S, which is free at the end C, and is constrained to move only longitudinally at A.

To the free end of the rod a mirror, T, is attached. The vibrating end consists of a steel bar 100 centimetres in length, and of rectangular section (1·51 centimetres by ·60 centimetres), clamped in a massive iron frame in such a manner that the length of the vibrating segment can be varied at will. A rider is used for the final adjustment of the period of vibration. The reed with the electrical arrangement for maintaining it in vibration is shown in

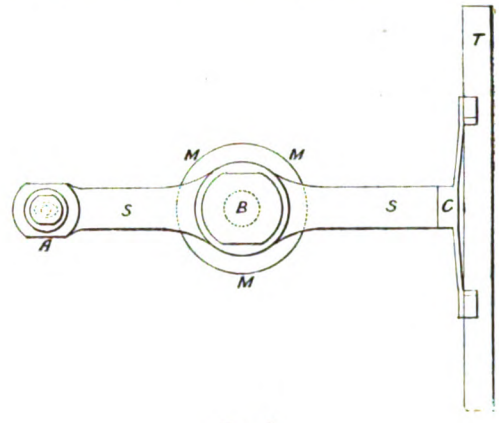

FIG. 1.

Fig. 2. A A A is the vibrating reed, C C the massive iron support to which it is clamped by the bolts and nuts D D. This support is itself clamped to a wooden block resting on a concrete floor. F F F is a wooden bar carrying the electromagnet M, and attached to the iron support at N N. On the side of the reed opposite to the electromagnet is a pair of springs S_1. One of these remains in contact with the bar, while the other makes and breaks contact with the first at each vibration. The two springs are connected through the electromagnet with the poles of a battery. A mirror, T, is attached to the free end of the reed. The apparatus is arranged so that the planes of motion of the rod attached to the revolving disc and of the vibrating reed are at right angles, and, therefore when synchronism is attained a spot of light reflected in both mirrors successively will be spread out into an ellipse, and the permanency of the ellipse will afford a test of the continuance of equality between the periods of rotation of the disc and the period of vibration of the reed.

In order to determine the vibration period of the reed a second pair of springs, S_2, exactly similar to the first pair, is placed opposite to them on the other side of the reed. These two springs are connected through a Morse receiver with a battery, so that a series of dashes will be recorded on the tape, the space occupied by a dash

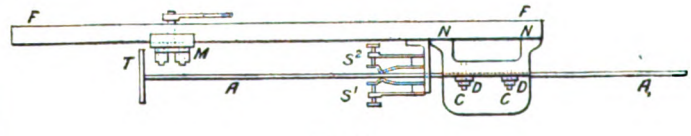

FIG. 2.

and the corresponding blank giving the period of vibration. To ascertain this, time signals are simultaneously recorded on the tape by means of a standard clock in the ordinary manner. By taking a sufficient interval of time the comparison may be made with any desired degree of accuracy.

The principal defect of the method is the impossibility as at present arranged of maintaining the rate of vibration of the reed constant, the variation exceeding one part in 1,000, while for the purpose required it should certainly not exceed one part in 10,000.

Prof. AYRTON observed that, in order to maintain the vibration period constant, the impulse should be given at the neutral point instead of at the extremity of each oscillation. Prof. Perry and himself had shown in a Paper communicated to the Society that it was possible to obtain a large number of notes of the harmonic scale from a single electrically maintained Koenig's tuning fork by simply altering the position on the fork, of the screw which made electrical contact.

Mr. BLAKESLEY stated that any disturbance, such as might be caused by persons moving about the room, or by the opening or

Digitized by Google

shutting of a door, would disturb the uniformity of the vibration. He also stated that it was possible to maintain the period of vibration constant to within 1 part in 10,000 if the vibration were maintained by constant wind pressure instead of electrically.

Prof. S. P. THOMPSON said that when he saw the author's diagram on the black board he thought he was going to give them a method of giving the impulses at the neutral point. He thought this might be effected by means of a pair of springs making and breaking contact on opposite sides of the reed, and connected through an electromagnet with a battery. He stated that Langdon Davies, who is engaged in researches not yet published on harmonic telegraphy, has succeeded in constructing electric vibrators of constant period which give much better results than have been obtained with tuning forks. He thought that the author's apparatus would work better with a tuning fork in place of a reed, as it would not so readily communicate vibrations to the stand.

Prof. G. CAREY FOSTER suggested that a very simple method of determining when a vibrator, such as a reed or tuning fork, was in synchronism with a revolving disc, would be to attach a vibration microscope to the vibrator, and view through it a point on the revolving disc, which would, of course, have to be placed with its plane perpendicular to the axis of the microscope. When in synchronism a point at a suitable distance from the centre of the disc would appear to move with simple harmonic motion in a straight line.

Dr. HOFFERT then read a Paper by R. Threlfall and A. Pollock, of the University of Sydney, on

"The Clark Cell as a Source of Standard Currents, and on its Application to the Calibration of Sensitive Long Range Galvanometers."

The authors quite agreed that of the two possible methods of measuring small currents in absolute measure that adopted by Sir William Thomson in his ampere balances was preferable where the main consideration was the attainment of the greatest possible accuracy. In these instruments the action of the earth's magnetic force was entirely eliminated, and the only corrections which had to be applied were for the variation of gravitation at different places on the earth's surface. They were, however, subject to the inconvenience that it was necessary to maintain the force balanced in order to obtain a reading, and for many purposes a slight amount of accuracy might advantageously be sacrificed in order to obtain continuous and automatic readings. The authors have recently been endeavouring to construct for this purpose a galvanometer capable of giving very accurate measurements, and it occurred to them to examine the applicability of the Clark cell to obtain a standard current for calibrating the galvanometer from time to time, in order to correct for small secular changes in the magnetism of the controlling magnets or in the strength of the earth's magnetic field.

They found that a constant current could be obtained from the Clark cell provided the current taken from it did not exceed a certain value depending on the size of the cell. The Paper, which is a lengthy one, contains the results of a large number of experiments on Clark cells considerably larger than the ordinary type. These experiments have led the authors to the following conclusions :—

1. When a current is taken from a Clark cell, the terminal E.M.F. drops practically instantaneously to within an almost inappreciable amount of its final value.
2. At all events, to the first degree of approximation this value is constant, and shows that the electromotive force of Clark cells giving small currents is constant, and the same as when they are at rest.
3. There is no appreciable secular change.
4. The statement contained in 2 is true at all ordinary temperatures since the cell resistance is always small and there is no polarisation.
5. When the current is stopped the terminal E.M.F. rises instantaneously to within a few thousandths of a volt of the original value, showing again that the polarisation is practically *nil*.
6. The cell completely recovers in time.
7. The above statements are only true when the current does not exceed a certain value depending on the cell. For a cell in which the zinc and mercury surfaces have each an area of about five square inches or upwards a current of ·001 ampere will not be too great. For the ordinary small test-tube cell the current should not much exceed the hundredth of this.
8. When too large a current is taken from any cell the E.M.F. goes on dropping for some time, after which it rises slightly and seems to tend towards a fixed value.

The galvanometer described in this Paper, and shown in the accompanying illustration (Fig. 1), was intended for use in one of the hospitals of the Colony, and an accuracy within about 5 per cent. was all that was required, but the instrument was constructed to give results accurate within about one per cent.

The principal features of the instrument are—

1. The arrangements made for the support of the controlling magnet and for its adjustment without disturbing the suspension.
2. The damping of the needle by means of a thin copper cylinder suspended by a fine wire in clove oil.
3. Mechanical arrangements allowing of easy suspension of the mirror and adjustment of the damper.
4. The arrangement for testing with a Clark cell.
5. The curving of the scale in such a manner as to obtain direct tangent readings.

The instrument was provided with a single coil of rectangular section, having both its axial and radial dimensions 1·3 centimetre

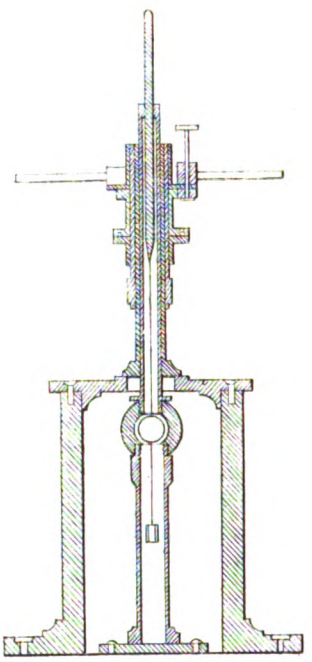

FIG. 1.

and 3·7 centimetre as radius of the inner layer. The coil consisted of 200 turns of copper wire ·0711 centimetres in diameter, and having a resistance of 2·02 ohms at 16° C, and was arranged to slide backwards and forwards with respect to the suspended portions while remaining parallel to itself.

Three positions of the coil were marked with respect to the suspended needles, and Mr. Adair, of Sydney University, calculated, by Maxwell's method of expansion in spherical harmonics, the law of deflection up to deflections of about 15° for each of these positions, and found that the deviation from the tangent law would never cause an error of more than 0·5 per cent.

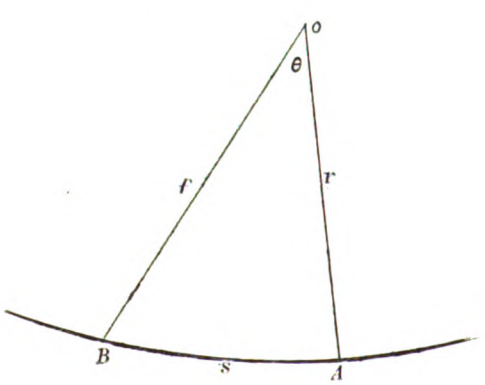

FIG. 2.

Mr. Adair also determined the form of the curve into which the scale of equal parts had to be bent in order to give direct readings, and a wooden block was cut to this form, and the scale attached to it.

This problem does not appear to have been worked out before, and the solution is of sufficient value to be placed on record.

Let A B (Fig. 2) be a portion of the curve required. Let O A = r be the apsidal distance, θ the polar angle subtended by the arc A B = s, O B = f, the distance of the spot of light from the mirror. A O is the line of incidence of the light.

Digitized by Google

Assuming that the deflections obey the tangent law, the curve is given by the equation

$$S = 2\int \tan \frac{\theta}{2}$$

or,
$$\frac{ds}{d\theta} = \int \sec^2 \frac{\theta}{2}$$

whence
$$\left(\frac{df}{d\theta}\right)^2 + f^2 = \int^2 \sec^4 \frac{\theta}{2}.$$

This cannot be solved in general terms, but an approximate solution can be obtained if the range of θ is small.

Let $f = r + \lambda$, then developing in powers of θ, and retaining powers up to θ^4, the differential equation becomes

$$\frac{1}{r^2}\left(\frac{d\lambda}{d\theta}\right)^2 = 2\left(\frac{\theta}{2}\right)^2 + \frac{7}{3}\left(\frac{\theta}{2}\right)^4 - 2\frac{\lambda}{r},$$

writing λ^1 for $\frac{\lambda}{f}$ thus becomes

$$\frac{d\lambda^1}{d\theta} + \left(\frac{\sqrt{2}}{\theta} - \frac{7\sqrt{2}}{48}\theta\right)\lambda^1 = \frac{1}{\sqrt{2}}\left(\theta + \frac{7}{48}\theta^3\right)$$

whence

$$\lambda^1 = \theta^{-\sqrt{2}} e^{\frac{7\sqrt{2}}{96}\theta^2}\left\{c + \int \theta^{\sqrt{2}} e^{\left(1 - \frac{7\sqrt{2}}{96}\theta^2\right)} \frac{1}{\sqrt{2}}\left(\theta + \frac{7}{48}\theta^3\right) d\theta\right\}$$

Now $\lambda^1 = o$ when $\theta = o$, so that $c = o$, and to the order of θ retained

$$\lambda^1 = \frac{\sqrt{2} - 1}{2}\theta^2 + \frac{4 - \sqrt{2}}{96}\theta^4 = \cdot 207\,\theta^2 + \cdot 0269\,\theta^4.$$

The Clark cell used to standardise the instrument had a mercury surface of about 12 square inches, the zinc surface being slightly less. The cell was coupled up in series with a platinoid resistance of 1,417 legal ohms, which gave a current of ·001007 amperes, which was near enough for the purpose.

To set up the galvanometer the coil was pushed up towards the suspended magnet as far as it would go, and this was called the position O. The controlling magnets were then raised so as to give a mean sensitiveness, the known current put on, and the double deflection observed and indicated by a fiducial mark on the scale.

If any subsequent change in sensitiveness took place it would merely be necessary to bring the coil up to the O position, and then raise or lower the controlling magnets until, with the standard cell and the same resistance in circuit, the deflection reached the fiducial mark.

With the coil in a certain definite position, A, ·001 ampere corresponded to 10 scale divisions, and in a second marked position, B, the same current gave a deflection of one scale division. These positions were determined by the aid of a large storage cell, the E.M.F. of which was tested during the progress of the calibration. The galvanometer was tested in this way from ·001 ampere up to ·4 ampere, and found to give satisfactory results.

A METHOD OF EXAMINING RATE OF CHEMICAL CHANGE IN AQUEOUS SOLUTIONS.*

BY G. GORE, LL.D., F.R.S.

This research supplies an outline of a method of examining chemical change based upon the application of the "voltaic balance" to measuring the relative amounts of voltaic energy of electrolytes (*see* Roy. Soc. *Proc.*, Vol. XLIV., pp. 151, 294; *ibid*, Vol. XLV., p. 268), and the rate of chemical change is indicated by alterations in amount of such energy.

The author gives an example of two liquids, viz., a solution of equivalent proportions of potassic iodide and chlorine, and one of chloride of potassium and iodine, which, although having the same ultimate chemical composition, are greatly different, viz., as 31·76 to 1·0, in amount of voltaic energy.

The results of the experiments show that the solution of potassic iodide and chlorine was very unstable, highly sensitive to rise of temperature, had a great tendency to lose its voltaic energy, to change its chemical composition, and approach that of the other mixture. That the solution of the latter was very much more stable and much less sensitive to heat, but had a feeble tendency to absorb energy, to change its chemical composition, and approach that of the solution of potassic iodide and chlorine. The effect, therefore, of heating both liquids was to produce two portions possessing similar chemical composition and properties, consisting of about ·23 part of potassic iodide, 74·49 of potassic chloride, 126·8 of iodine, and ·0497 of chlorine. They also show that the solution of potassic iodide and chlorine decomposes spontaneously at 12° C. into potassic chloride and free iodine; that more than six days are necessary to effect the complete chemical change at that temperature; and that the rate of chemical change is much greater at the commencement of the action than towards its termination.

The collective results show that the "voltaic balance" method may be used to detect chemical changes of aqueous solutions, and to measure their rate. Its great advantage over the colorimetric method is that it is equally applicable to colourless liquids; it is much more sensitive and exact usually than either the colorimetric or the thermo-chemical method; and it is quick and easy of performance. It is being used to detect and measure chemical changes produced by light in aqueous solutions. The degree of freedom of an aqueous solution of chlorine from hydrochloric acid, and of iodine from hydriodic acid, was ascertained much more readily by this method than by ordinary chemical analysis.

* Abstract of a Paper read before the Royal Society, March 14, 1889.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"The Electrician" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and now makes over 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

THE ANGLO-CONTINENTAL CABLES.

On Monday last the proprietors of the cables which have connected this country with France for a period of forty years, and with Belgium for thirty-six years, resolved to give up possession, and on Monday next these cables will be in the hands of the several Governments. The terms of purchase have not even yet been definitely agreed upon; but the directors of the Submarine Company obtained the authority of their shareholders to make the best bargain they can with the Treasury, and to place no obstacle in the way of the working transfer on the 1st of April. As to the price now offered for the cables we shall have something to say presently; but whatever comes of it, the event is of singular importance, not merely for the commercial interests now involved in the change of ownership, but because of the historic memories associated with a group of telegraph cables which will ever be regarded as the first parents of submarine telegraphy. Encouraged by certain experiments in crossing rivers and short stretches of water by means of insulated telegraph wire, Mr. Jacob Brett and others associated with him conceived the idea—a bold one at that time—of spanning the Straits of Dover, and thus connecting the two friendly nations on either side by an unbroken system of electric communication. In 1849 a concession for ten years—afterwards extended to forty—was obtained from the French Government, subject to a practical demonstration of the feasibility of the project within twelve months. This period of grace was by no means too long, for there existed really no data to go upon, and, both in respect to the character of the cable and

Digitized by Google

the appliances for laying it, the promoters were almost in entire darkness. By a piece of good fortune they saved the concession; but they lost their cable, and had to begin the work over again. The facts are worth recalling. Dover and Cape Grisnez were respectively the points chosen for landing, and a copper wire, No. 14 gauge, covered with gutta-percha to the thickness of about half an inch, was to be the connecting link. This was the first submarine cable; and the machinery for paying it out was of an equally primitive type. Between the Admiralty Pier at Dover and the water's edge the gutta-percha was protected by a lead covering, but otherwise the cable was bare, and it had to be heavily weighted at intervals to induce it to sink to the bottom. In due course the boat which was paying out the cable arrived off Grisnez, where a lead covered cable had been provided on the shore, and to which the sea length was successfully attached. This was on the 24th August, 1850, and on that day—we believe from a bathing machine on the sands—intelligible signals were exchanged with the country from which the cable had been shipped. For the purposes of the concession, the experiment was a proved success; and it mattered little that a French fisherman next day accidentally hooked up the cable and cut it adrift with his pocket knife. He probably only anticipated by a few hours the catastrophe to which such a cable was certainly doomed.

By the following year a far stronger cable, approaching more nearly to the modern type, had been constructed, money being forthcoming to meet the additional cost now that the practicability of submarine telegraphy had been demonstrated. Four conductors of No. 16 copper wire, covered with gutta percha, served with tarred Russian hemp, and finally protected by ten thick galvanised iron wires, constituted the new cable, which was 24 miles long, and connected Dover with Calais. Though historically the second among submarine cables, the Dover-Calais cable was practically the first, and was certainly one of the best ever laid. The Grisnez line was perhaps never seriously regarded as permanent, and, at all events, was entirely abandoned. Only another year elapsed before a fresh cable was required to meet the traffic between England and France, and in the year following, 1853, a third cable was submerged, this time to connect us with Belgium. Anglo-Dutch and Anglo-German cables followed in due course, and in less than ten years from the commencement of its operations the Submarine Telegraph Company were working at least half-a-dozen excellent cables, ranging from 25 to 117 miles in length, connecting England with the Continent. That the business was highly profitable there is no doubt whatever, and, knowing what we do about cable laying, the risk was inconsiderable. But it appeared to be far greater in those days, and we cannot withhold our testimony to the courage and energy of the directors of this great company, who certainly paved and led the way for the greater enterprises which have resulted in submarine telegraphy throughout the whole world.

We have no exact knowledge as to the cost of the Anglo-Continental cables, the purchase of which is now under discussion, and any calculation is perhaps vitiated by the circumstance that the owners would naturally take into account the expense of repairs and maintenance, whereas the purchasers equally naturally consider this outlay as so much detracted from the intrinsic value of the articles. What the Government propose to do is to pay for the four French and the two Belgium cables about a quarter of what it would cost to lay entirely new cables of modern type. This, at least, is the estimate of the Chairman of the Company, and of course he is far from satisfied with the proposition, the expectation being that the shareholders would receive not less than twice as much. According to the only figures at our disposal, the aggregate length of the cables is about 370 statute miles, and reckoned at the price the Government propose to pay for them, namely, £22,330, their value per mile is set down at £60, or thereabouts. This is a ridiculously low figure, and we are not surprised that some of the shareholders described it as representing little short of spoliation. The cables, it is true, are the oldest in existence, but they appear to have suffered far less from age than from the accidental injuries inflicted by the anchors of fishing boats, which swarm in this very busy channel—injuries to which perfectly new cables would be as liable as the old. From the point of view of the Company, their submarine property is in good working condition; and when we are reminded that the cables have earned a net revenue in the last six months equal to the price now offered for them, it is impossible to deny the substantial accuracy of the description. Possibly one or two new cables may have to be laid in order to meet the higher requirements of the Government administration, but that would be a purely voluntary expenditure, for which the French and English nations will be amply recompensed, and affords no justification for appropriating the existing cables at little more than the price of old stores.

No doubt the chief difficulty in adjusting this bargain equitably now rests with the French Government, who, being hindered by the British Government from renewing the company's concession, have turned round and declined to be led in the matter of the purchase. The British Government, therefore, were responsible for the cancellation of the concession, and for the provisional agreement of July, 1878, which afforded the Company reasonable ground for supposing that their application ten years later would not be opposed. Certainly there was no reason to anticipate that their business would be compulsorily extinguished, and their property partially confiscated. This being the case it seems to us that the clear duty of the CHANCELLOR of the EXCHEQUER is to exert himself to the utmost in bringing the French Government to a more reasonable view as regards the value of these cables. The actual amount in dispute is a mere bagatelle, and divided between two of the richest nations in Europe is really not worth arguing about. From the company's standpoint, however, and also from that of all the companies possessing submarine cables connected with these shores, the principle involved in the transaction is a very important one; and we trust that it may not result in establishing a precedent which would be disastrous if applied to corporations which do not possess the peculiar advantages so long enjoyed by the SUBMARINE TELEGRAPH COMPANY.

REVIEWS.

Treatise on Submarine Telegraphy. By M. E. WÜNSCHENDORFF Director of Military Telegraphy, France. (Paris: Baudry and Co. 1888.)

(FIRST NOTICE.)

This very large and comprehensive treatise on submarine telegraphy of 565 quarto pages supplies a long and much-felt want. It exhibits from beginning to end an amount of careful research, skilful and systematic compilation, as well as a thorough knowledge of the subject. It is certainly most remarkable that it should have been left to a French officer to write the first and only complete treatise upon this important and interesting topic when we consider the fact that more than 90 per cent of all the submarine cables in the world have been projected, designed, made, laid, and are maintained by British capitalists, electricians, manufacturers, and telegraph companies. British submarine cable manufacturers and electricians have naturally been very conservative in regard to their special knowledge and experiences. They were the practical and successful pioneers of submarine telegraphy, and having spent a

Digitized by Google

great deal of thought, time, and money in acquiring their knowledge, they could scarcely be expected to publish all they knew about it. No doubt a large amount of the information found in M. Wünschendorff's book has been compiled from English publications (he acknowledges some of these sources), yet there is a very great deal that has never before appeared in any English journal or book, more especially in regard to the manufacture and laying of cables, which will be read with interest even by those most intimately acquainted with these operations. M. Wünschendorff has had exceptional opportunities of becoming intimately acquainted with all the various details connected with submarine telegraphy, for he has taken a leading part in the laying and repairing of most of the French Government cables. He was sent over to the India Rubber and Gutta Percha Company's Works, Silvertown, to test and inspect on behalf of his Government certain cables made by that firm, and he was also on board the Eastern Telegraph Company's cable ships s.s. "John Pender" and s.s. "Chiltern" when they were engaged in laying and repairing French Government cables in the Mediterranean.

We shall first give a general idea of the scope of this treatise, and then refer more particularly to some of the details. It is divided into five parts :—

I. The History of Submarine Telegraphy from the original idea, and experiments by Sœmmering carried out at St. Petersburg in 1807 until the immersion of the 1886-87 Atlantic cables.

II. The Composition and Manufacture of Submarine Cables.

III. The Laying and Repairing of Submarine Cables.

IV. The Testing of Cables during Manufacture and Laying, as well as for localising the position of faults.

V. The Apparatus and Systems Employed in Telegraphing by Long Submarine Cables.

Part. II. is divided into five chapters—(1) Conductors ; (2) Insulating Coverings ; (3) Outer Sheathings and Servings ; (4) Different Kinds of Cables, and their resistance to breaking ; (5) Jointing and Splicing Cables, with extract table of specifications of different cables from Rankine's Rules and Tables (Sixth Edition).

Part III. is divided into five chapters—(6) The Machinery and General Arrangements of Cable Ships ; (7) Grappling and Buoy Ropes, Chains, Mushrooms, Grapnels and Buoys ; (8) Sounding and Surveying Apparatus and Preliminary Surveys ; (9) Laying of Submarine Cables ; (10) Repairing of Submarine Cables.

Part IV. is divided into four chapters—(11) Testing Instruments, such as Galvanometers, Electrometers, Wheatstone Bridge, &c., and Batteries ; (12) Testing of Batteries and Galvanometers ; (13) Measuring the Conductor Resistance, Insulation Resistance, and Capacity of Cables, Testing Joints, Tests during Submersion of Cables, Examples of Test Forms ; (14) Localising Faults by Different Methods.

Part V. is divided into two chapters (15) Theory of the Transmission of Signals, Employment of Condensers, and Speed of Signalling ; (16) Sending and Receiving Apparatus, such as Relays, &c., Sir William Thomson's Mirror and Siphon Recorder, Duplex and Quadruplex Telegraphy.

The historical part is very interesting, and tells a tale that has been often told before. It is, however, put in an agreeable and readable style ; it brings forcibly before the reader the difficulties which beset and were surmounted by the pioneers of submarine telegraphy, and on the whole awards just credit to those who most prominently took a lead in the same. The early designs of Wheatstone for making and laying cables, as published by Sabine in 1877 in the *Journal* of the Society of Telegraph-Engineers, have been neatly reproduced and explained. The work done by Brett, Read, Willoughby Smith, F. C. Webb, and others is duly taken notice of. Very clear and well done illustrations of some of Newall and Co.'s early cables, of the 1857 and 1866 Atlantic cables, of the paying out gears of the "Agamemnon" and the "Dix-Décembre" (still at work on the Channel cables and now called the Ampère), together with charts of the routes taken by the North Atlantic cables near their landing places in Europe and America, and a large general map of the present chief cable routes, prepared from official documents supplied by the International Bureau of Telegraph Administration, are to be found in this part of the book. The commercial and administrative aspects of this interesting period in the history of submarine telegraphy have naturally been omitted in a book dealing almost exclusively with electrical and mechanical details : consequently, the names of those who most prominently sustained and maintained these undertakings by their courage and pecuniary support have not been mentioned.

In Part II. an exhaustive analysis of the mechanical and electrical qualities of copper, and the reasons assigned for its use as the conductor of submarine cables, is given, together with illustrations of the apparatus used for stranding the conductor wires.

The cultivation of gutta-percha and India-rubber trees, the physical and chemical properties, the purifying and methods of covering the conductor with these dielectrics, are very fully explained and illustrated. The improved gutta-percha by Willoughby Smith, with tables of tests after one minute's electrification, is also noted. Other insulating substances, such as Hooper's core, Wray's composition, ozokerite, nigrite, kérite, Bruce Warren's India-rubber, the cables of Berthoud-Borel and Brooks, are here referred to. We would, however, have expected to find more information and illustrations of these newer kinds of insulating material than has been given by M. Wünschendorff.

Chapter 3 deals with the preparation, the mechanical resistance and machines for covering cores with hemp. It then treats of the iron sheathing and the various machines employed by manufacturers in covering the core with the iron armour and outer coverings, of Clark and Bright's bituminous composition, as well as Messrs. Johnson and Phillips' tape. We are astonished, however, to find no mention of the method of applying Clifford's brass or Muntz's metal tape, which is so largely used by the Telegraph Construction and Maintenance Company to cover the gutta-percha cores of the Eastern Telegraph Company's cables, so as to prevent them being pierced and damaged by teredoes and other marine borers (*see* "Munroe and Jamieson," Sixth Edition, page 279).

Chapter 4 deals with multiple conductor cables, and illustrates the cable made by M. Menier for the mouth of the Seine, as well as the machine for serving the multiple cores with jute yarn. Next we have an illustration of an old-fashioned tripod apparatus for testing the breaking stress of cables, with a few remarks on the depth to which cables of different strengths may be prudently submerged without breaking during laying. The light cables proposed by Baudoin and Allan, Siemens, Duncan, Rowett ; floating cables, Blondot and Bourdin, and finally those of Captain Trott and Mr. Hamilton (the latter being beautifully illustrated), are severally mentioned and their peculiarities reviewed. M. Wünschendorff concludes this chapter by alluding to the great inequalities frequently met with by cable engineers in different parts of the world, especially noticing a case of sudden inequalities in the Levant, found by the reviewer, and draws the conclusion that light cables would fare very badly under such circumstances. We fancy that Messrs. Trott and Hamilton would take another view of the case, and affirm that their light cables would so beautifully fit the sinuosities of the bottom of the ocean that they would seldom, if ever, require repair. Chapter 5 is very complete in regard to the scarfing and soldering of the conductor, the making of gutta-percha joints, as well as the splicing of the sheathing and lapping with outer serving, but incomplete and not illustrated in regard to India-rubber or Hooper's core. We fancy that M. Wünschendorff has had no practical experience with these kinds of core, and in a second edition he should make good this omission.

Chapter 6 begins with a reference to cable ships. The s.s. "Faraday" is instanced as a model ship for laying long cables, while the s.s. "Pouyer-Quertier" is considered as the type of repairing ship. No plans of any modern cable ship are given, and we consider this an omission which M. Wünschendorff should remedy in the next edition. The separate details of the cable machinery, however, receive considerable attention and illustration, such as cable tanks and their fittings, coiling of cables in tanks, changing of tanks during paying out, and the formulæ for ascertaining the length of cable that can be coiled in a tank. A curious omission is made here in not taking into account

Digitized by Google

the percentage loss of length due to wooden feather edge. Mere reliance on the formulæ will not give accurate results, as it supposes perfect coiling without the necessary intervening slips of wood. Excellent illustrations are given of a paying-out drum, with double Appold brakes and dash pots, as well as picking-up gear, but no mention is made of the makers or the ship to which these were applied. We may here point out a general fault throughout the whole book, viz., that no descriptive names of the different illustrations are given under any of the figures, simply the number, which necessitates turning over the text to find out their meaning and object. This defect should also be rectified in a second edition. The only illustration given of a dynamometer is the old one of the Great Eastern. These useful instruments have been considerably improved upon. M. Lacoine's mathematical investigation (which appeared in *Engineering* in 1885) of how to calculate the dynamometer readings is reproduced in full, but no reasons are given for the statement "that the cable stresses are not accurately indicated by the dynamometer when the cable or grapnel rope is in motion." The bow-baulks gear of the s.s. "Faraday" is illustrated and described, but the method employed by the Eastern Telegraph Company of building in the bow-gear along with, or making it a part of, the ship, and thus constructing a comfortable, easy platform to work upon, as well as of rendering the whole thoroughly firm and secure, is preferable for small repairing vessels to the one-sheave swivel arrangement on board the "Faraday."

Chapter 7, as we have already mentioned, deals with grapnel and buoy ropes, shackles, chains, mushroom anchors and grapnels. The *old* form of Jamieson's self-relieving grapnel is given at p. 216. Lambert's grapnel for hooking a cable at great depths, and then cutting and relieving one side, but holding on to the other, is fully described, but we find no mention of the more successful Messrs. Johnson and Phillips' patent grapnel, which aims at effecting the same purpose. Kingsford's tell-tale grapnel, with central insulated conductor from the fillets of the grapnel toes to the ship, with battery cell on board for automatically announcing to those in charge when the cable has been hooked, is neatly illustrated and described, but it is condemned for great depths. Now, this modification of the ordinary grapnel is more especially useful at great depths, first, on account of the great difficulty of knowing when the cable has been hooked with a long drag-rope and heavy normal stress on the dynamometer; and, secondly, from the long time occupied in making sure that it has been fairly hooked by having to heave up the slack before the peculiar springy feeling of "cable hooked" is experienced. We understand that Captain Trott has successfully used this grapnel in depths of 2,000 fathoms and upwards in repairing Atlantic cables.

M. Wünschendorff is mistaken in stating that grapnel ropes exclusively of Manilla have been used for great depths to minimise the normal stress, the practice being to have, say, two or three hundred fathoms of ordinary grapnel rope next the grapnel chain, then Manilla, and sometimes a length of ordinary grapnel rope next the ship, so that the wear and tear which must naturally take place at each end is withstood by the ordinary compound rope, whilst the long intermediate length of Manilla rope greatly lessens the normal working stress. One of the best-illustrated and described portions of the book is that which deals with buoys, but a table of the depths for which each kind and size of buoy is most suitable, as well as the composition, sizes and weights of buoy and grapnel ropes, would have still further improved it. A most vivid full-page picture is given of the "Great Eastern" lying off a big Atlantic buoy prior to picking it up, the ship's dingy boat being kept close up to the latter until the agile cable-hand, who is struggling manfully in his perilous position, unships the buoy moorings. In the next illustration the buoy is represented as being heaved on board the great ship.

Chapter 8 is devoted to sounding and sounding machines, Sir William Thomson's well-known deep-sea sounding machine receiving full attention, as well as the many devices for slipping the sounding weight when it reaches the bottom in deep water, Mr. Chas. H. Phillips's method being attributed to a M. Benest (*see* Figs. 215, 216). Flying soundings are merely referred to, and we think that M. Wünschendorff might have introduced a figure of Sir William Thomson's latest form for this purpose, which is now a recognised necessity on board not only every cable and surveying ship, but also every passenger ship of importance. This chapter concludes with a *résumé* of some of the more important marine surveys. Too much stress cannot be laid upon the importance of thoroughly surveying and selecting the most suitable route and bottom for a cable *prior* to its immersion. *a. γ.*

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

Section III.—Magnetic Fields of Coils and Solenoids.

(*Continued from page 540.*)

148. *Direction of Field Due to a Solenoid.*—A solenoid, mounted as in Fig. 143, is very suitable for observing the direction of field set up. One layer of stout wire, say, No. 12, is first wound round a cylindrical surface such as a battery jar, to give it the proper shape which it will be found soft enough to retain itself after slipping off. It is better to leave a little clear space between each turn, so that afterwards when experimenting you can look down into the middle of the coil. If this is done there is no need to have the wire insulated. Let the two ends be passed through the wooden base block B carrying the two terminals, and solder the wires underneath this block to the extremities of the terminals. Clamp the coil down by a flat piece of wood screwed down to the base block, as shown This keeps the solenoid firmly in position, and affords a little table whereon to put your compass needle when examining

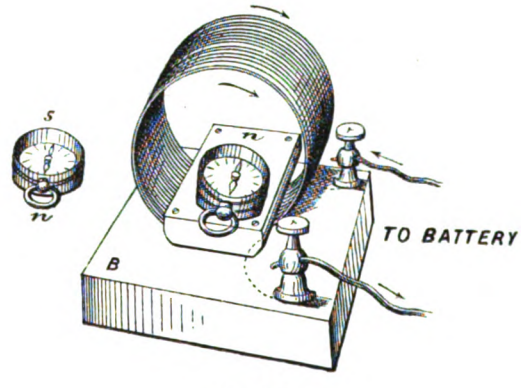

Fig. 143.

the field in the interior. A convenient size of solenoid is about from four to six inches in diameter, and, say, one foot long. Before passing the current through let the solenoid be placed so that the direction of its length is at right angles to the magnetic meridian, and then put a compass needle inside, or, better still, place the compass inside first and then turn the whole apparatus bodily round till the needle points at right angles to the direction of length of the solenoid. If another compass needle be placed *outside* the solenoid in the position shown in the Figure, both needles will point the same way, north and south, before the current is passed into the coil; but immediately the current is switched on the needles will turn sharply in opposite directions, and when at rest will lie very nearly in the direction of length of the solenoid. Notice should be taken of the direction of the current and the direction of movement of the needles. In the Figure the needles are shown as they are deflected when the current passes through the solenoid in the direction of the arrows. We now see the direction of the field by the direction towards which the north poles of the needles point, and we find by exploring all round the solenoid that the lines seem to flow along the interior space of the coil and then to separate into two streams passing *backwards* along the exterior sides of the

Digitized by Google

coil, and then turning in again to the centre. This can be best observed by cutting out a piece of card as in Fig. 144 bending it upwards at the dotted line, and slipping it over the coil in the manner shown in Fig. 145, the centre portion, A, being then bent downwards again so as to lie along the interior of the coil. By passing the current through the coil again, and letting fine iron filings fall on the card, the character of the entire field is delineated. Supposing the current in

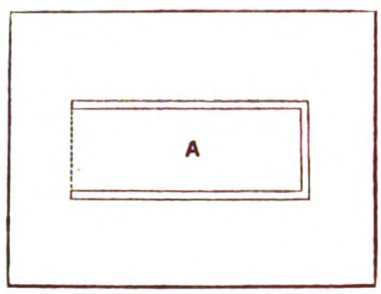

Fig. 144.

the coil to be in the same direction as in Fig. 143, we shall find that wherever we place small compass needles the direction in which their north poles turn will be along the arrows marked on the card, and the direction of field in any plane surface cutting the coil is exactly similar to that found on the plane of

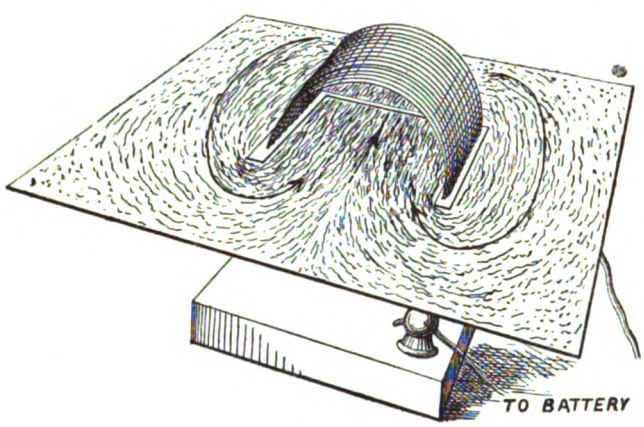

Fig 145.

the card; hence, when we think of the field of a coil or solenoid we must carry in our minds the conception that the field entirely envelopes the coil. In other words, the lines of force fully occupy the interior space of the coil, and after passing

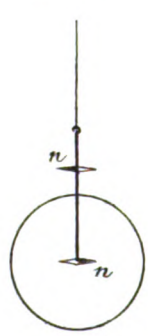

Fig. 146.

through this space divide evenly and flow *backwards* round the outside; and with this conception it will be easily understood that if we attach two magnetic needles rigidly together, as in Fig. 146, with their north poles pointing opposite ways, and freely suspend them by a silk thread, so that one is inside the coil and the other outside, as shown, both needles will turn in the same direction when a current is sent through the coil. The two needles together, or, as the combination is technically called, the "system of needles," is hardly at all affected by the earth's horizontal force, because what force it exerts on one needle is counteracted very nearly by the force on the other; in fact, if the two needles were of exactly the same magnetic moment, the "system," when allowed to swing freely in the earth's field, would not come to rest in any definite position, and hence the "system" is called an "astatic" system. It will be seen that as the earth's field has very little controlling effect on it (only just enough to keep it at zero) the astatic system is very sensitive. It is usual to have two separate coils, one above the other, and each containing and acting upon one of the needles, but when the idea was first developed one coil only was used. Faraday mentions in his renowned "Experimental Researches" the use he made of an astatic system with one coil (Fig. 146) in carrying out some induction experiments. And the writer has introduced it here believing it to be of interest in connection with the direction of field in and around one coil *alone*; and, indeed, in an earlier part of this series (para. 57) reference was made to the same subject, the explanation of which now will make the case there given better understood.

Lastly, if a compass needle placed inside the coil be moved outwards along the axis either way, it will be found that its deflection keeps pretty nearly in line with the axis until it emerges from the coil, when the deflection rapidly falls off; and ultimately, by removing the needle further and further away, we find the field of the coil exerts practically no more force on it, and it rests in the meridian once more. It is precisely this variation of field along the axis that we wish to determine for any kind of solenoid; and further than this, to determine in C.-G.-S. units the exact intensity of field at any point.

(To be continued.)

ARC LAMPS AND THEIR MECHANISM.*

BY PROF. SILVANUS P. THOMPSON, D.SC., M.I.E.E.

(Continued from page 572.)

In the Thomson-Houston lamps so widely used in the United States, a peculiar clutch is employed, consisting of a pair of levers jointed together, one of them being perforated with an eyelet through which the carbon rod passes. The mechanism of this lamp, shown in Fig. 14, consists of a see-saw lever, L L, pivotted at O, and provided with a long tail, T, the motion of which is moderated by an air dash-pot. Below is an electro-magnet, M, in the main circuit, and above is a second, S, which is connected as a shunt. The pole-pieces of both are of conoidal shape, protruding through apertures in the armatures, *a a*, and *b b*, to give longer range of pull. The lower and upper arms of the clutch, marked R and *k*, close together when the tail, T, rises, gripping the carbon rod, C, and raising it. From this diagram, which also shows the electric connections, it appears that the current entering the lamp through an insulated terminal at +P, flows first round M, and then goes to the frame of the lamp. Thence it divides, the main current finding its way to the upper carbon holder, and so through the arc to the lower carbon, whence it returns (by a route not shown) to the insulated negative terminal, −P. A smaller portion of the current flows up round the shunt electro-magnet to −P. The arc is struck by the preponderating main-circuit current in M attracting the lever end of the see-saw lever, and raising the clutch. The feeding is accomplished by the preponderating pull of the shunt magnet as the arc increases in length. The resistance wire across from +P to *c* constitutes a cut-out circuit, which is brought into operation by the augmented current in S on any failure of the main current. The small coil connected across from +P to the lamp frame is a mere adjustment to regulate once for all the power of the series coil, *m*, relatively to that of the shunt coil, S.

It will be noted that in the operation of all these clutch actions there are really four periods. In striking the arc there is a first stage of affairs, where the clutch rises sufficiently to grip the carbon rod, immediately followed by a second stage, during which it rises still further, and lifts the carbon rod, so striking the arc. During the third stage or period the clutch still retains its grip, but as the arc burns away the clutch is gradually lowered. This is due, in constant potential lamps, to the weakening of the main current; in constant-current lamps, to the increasing opposing action of the shunt. The fourth stage is reached when the arc has burned away so far that the clutch has been lowered to the point where it begins

* Paper read before the Society of Arts on March 6, 1889.

Digitized by Google

to relax its grip, and now feeding commences, the rod slipping a little, but the clutch simultaneously rises a little, and grips again, again to descend. In a well-adjusted clutch lamp the clutch is indeed incessantly rising and falling through minute distances about the critical position. A bad clutch, or one that is deranged by dirt, will overfeed, and then rise too far, feeding spasmodically. Theoretically, all these clutches possess the retractile property so useful in keeping a steady arc when the carbons are of indifferent quality. But it is obvious that their perfection of action is impaired by dirt, dust, and inequalities in the surface of the carbon rod due to wear and tear.

Clutches of the class termed "forward-feeding" belong to a different category, as they have, for the most part, no retractile power. In Newton's form (1623[83]) a piece of steel curry-comb, bent so as to form a sort of lobster-trap, encircles the carbon rod, and forces it gradually forward when mechanical vibrations are imparted to it by a lever, working with a vibration on the plan of the well-known electric-bell vibrator, from the armature of a shunt-magnet. The latest variety of this species of forward feed is that of Holmes (769[86]), shown in Fig. 15. Here, a shunt electro-magnet, S, attracts to the periphery of a wheel first grips the wheel, then turns it a little. In weaving machinery the "feed" acts in the direction in which the clutch propels the wheel, but in its application to the arc lamp the action is reversed, for the weight of the carbon rod propels the wheel in a direction opposed to the grip of the clutch, and the feeding takes place at those instants when the clutch releases its grip. The matter is best studied by reference to actual cases. Fig. 16 depicts the clutch-wheel of Common and Joel. The descending rack R drives the wheel D by means of the pinion P. Pivoted loosely around the same arbor is a heavy lever, which is prevented by a stop, S, from descending too far. Pivoted to this lever at L is a second lever, with an enlarged end to grip against the surface of the wheel. The tail of this nipping lever is attached by a pin to the iron core of the solenoid, M. (The latter is wound with a main-circuit coil only if wanted for use in parallel, or with a main coil and an opposing shunt coil if for use in series.) When the current in the solenoid draws up the core, the nipping lever first turns around L and grips the wheel; any further rise of the core will cause the two levers and the wheel to turn bodily together round the arbor, and this second action causes the arc to be struck.

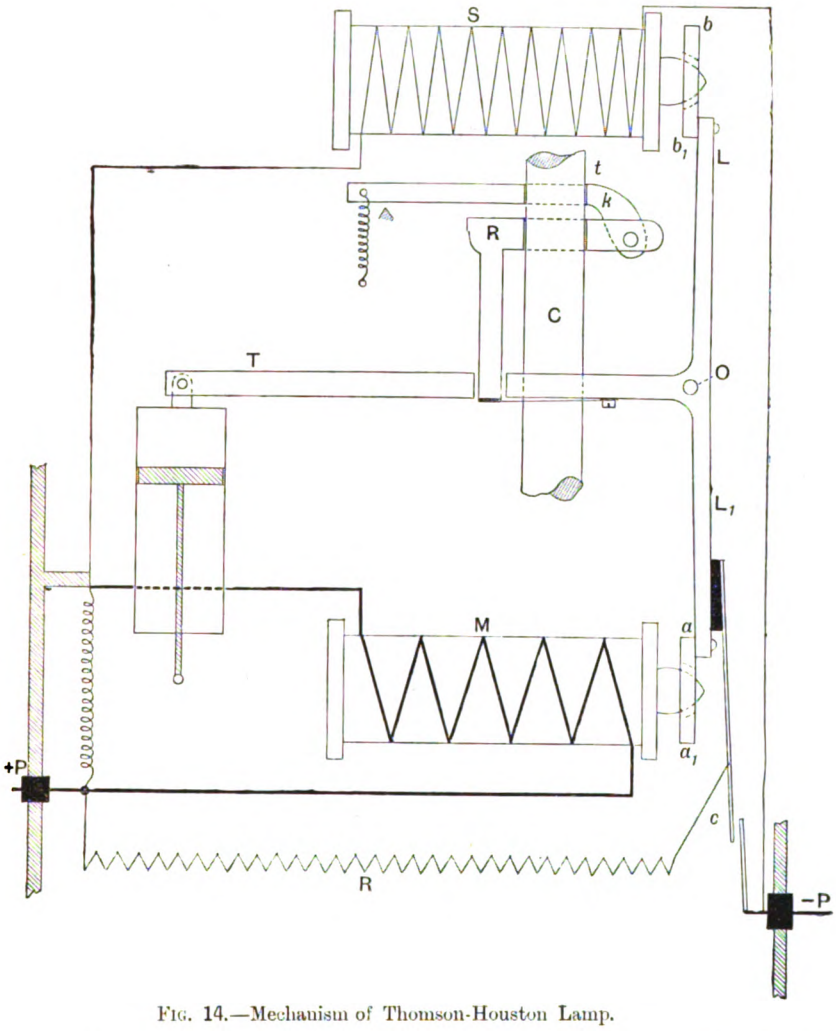

Fig. 14.—Mechanism of Thomson-Houston Lamp.

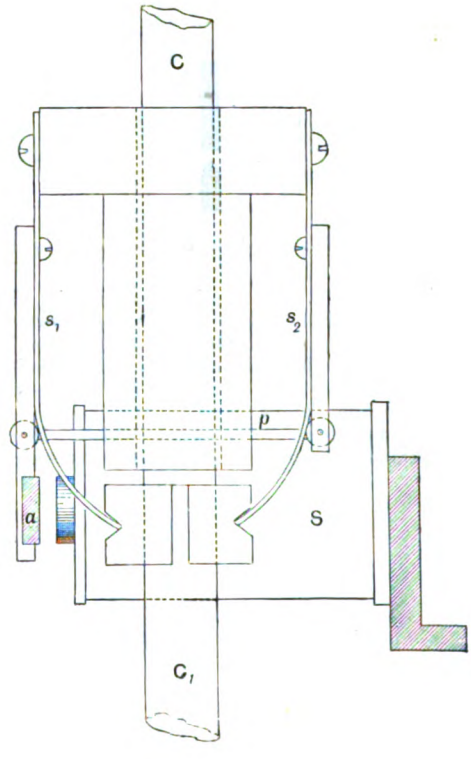

Fig. 15.—Holmes's Feed.

an armature, a; the latter being mounted upon a vertical lever. The carbon rod $C C_1$ is gripped between two blocks, which are pressed against its sides by two curved springs, s_1 and s_2. The armature lever is attached to s_1, and is connected across by a small rod, p, to the spring s_2. When the armature a is alternately vibrated backward and forward by the magnet, the gripping blocks propel the carbon downwards. The make-and-break device which turns the current off and on in the magnet coils is not shown in the cut. It consists of an ingenious modification of Holmes's snap-switch.

Passing to the *clutch wheel* or *brake wheel* type of lamps, we may remark that although so far back as 1861 Gramme attempted to construct on this plan a lamp (the existence of which was only published to the world in 1888 by M. Fontaine), this species of mechanism appears to be essentially British. The device of applying a clutch to a wheel in order to feed that wheel forward by degrees, the reciprocating motion of the clutch lever being converted into a motion of rotation of the wheel, is already familiar to engineers in the so-called "silent feed" movements used in spinning and weaving machinery. A clutch applied

Then begins the third period of action, during which the levers slowly descend until the weight-lever touches S. Then the fourth period begins; any further descent of the core causing the nipping lever to release its grip, and allowing feeding to take place, followed by a slight rise in the core and renewal of grip.

A form of clutch-wheel lamp which has become deservedly popular of late is that known as the Brockie-Pell (4419[82] and 12681[85]). The see-saw belonging to this lamp was shown in Fig. 6. The descending carbon rod drives a wheel having a strong projecting rim, at the inner surface of which a brake is applied. This consists of a small leather pad, m, fastened to a short arm which projects downwards from the nipping lever, L, pivoted at Q to a sector-shaped lever behind, which carries two weights, W W, to increase its downward-bearing power. This weight-lever is loosely pivoted on the arbor, P, and turns solidly with the wheel when the brake is applied. There is a stop, S, to limit the descent, but it is in this case applied to the tail of the nipping lever. A connecting link, E, joins the nipping lever, L, to the see-saw. The internal position of the brake appears to have two advantages, namely, longer leverage around the fixed pin, making the feed more sensitive, and

Digitized by Google

greater protection from dust and dirt. One peculiarity of the Brockie-Pell lamp is seen by reference to Fig. 6, namely, the device by which the core, B, of the shunt coil is allowed a certain travel upwards before it pulls at the see-saw lever, its thinner part passing freely through a swivelled washer, *w*, on the see-saw. But the washer is of iron, and the core has an enlarged head, *h*. These adhere by magnetic attraction when the shunt coil comes into operation.

Another very successful form of lamp is the Crompton-Crabb "double differential" (2539[83]), shown as a whole in Fig. 18, and in

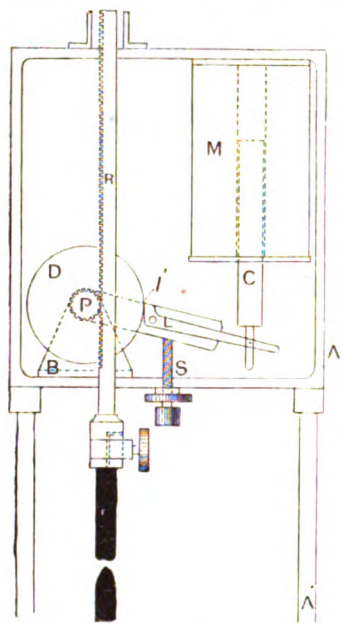

Fig. 16.—Common and Joel's Clutch-wheel.

detail in Fig. 19. In the lamp shown in Fig. 18 there are two carbon rods, M and N, of which N comes first into operation, afterwards changing over. On each carbon rod is cut a rack which drives a brake-wheel, or, rather, a pair of brake-wheels, one behind the other on the same pinion. The arbor bearing is not, as in the two preceding lamps, fixed in the frame of the lamp, but passes through a short sleeve or jockey, which, when the wheel is free to turn, can slide up or down on the carbon rod, but is prevented

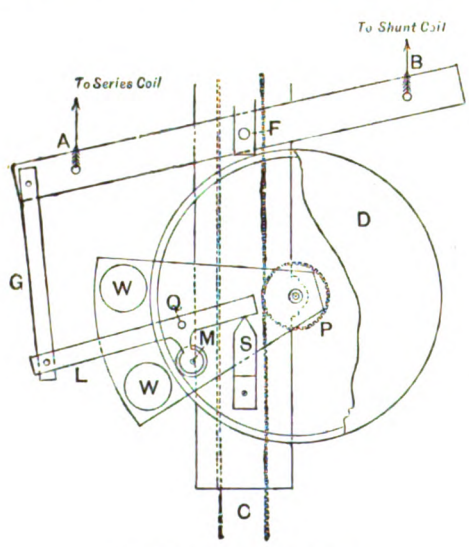

Fig. 17.—Brockie Pell Lamp.

from turning sideways by a guide-pin, *g*, above. Below the brake-wheels stands a lever, L, pivoted at *o*, and attached by a link, H, to the core of the solenoid overhead. This lever carries a small table, *t*, and a brake-piece, *b*, faced with phosphor-bronze. When the lamp is out of action, the free end of the lever is down, and the weight of the wheels and the carbon holder bears down upon the table *t* through a pin, *p*, which projects down from the jockey-sleeve. In this position the wheels do not touch the brake-piece, *b*, and are free. When the current is turned on, the main coil of the solenoid attracts its core, first drawing up the lever, which, turning on its pivot as it rises, brings the brake-piece against

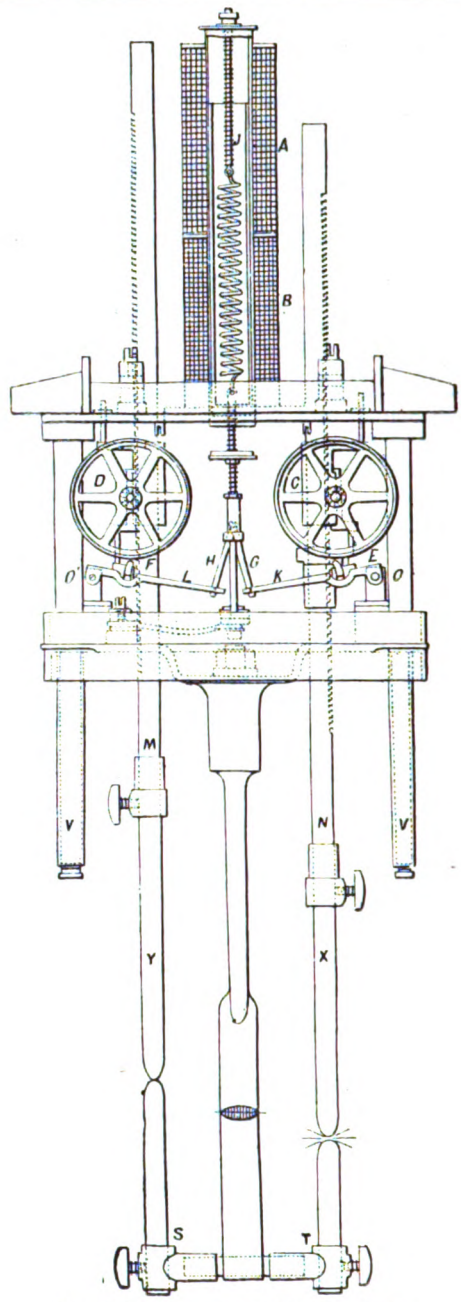

Fig. 18.—Crompton-Crabb D D Lamp.

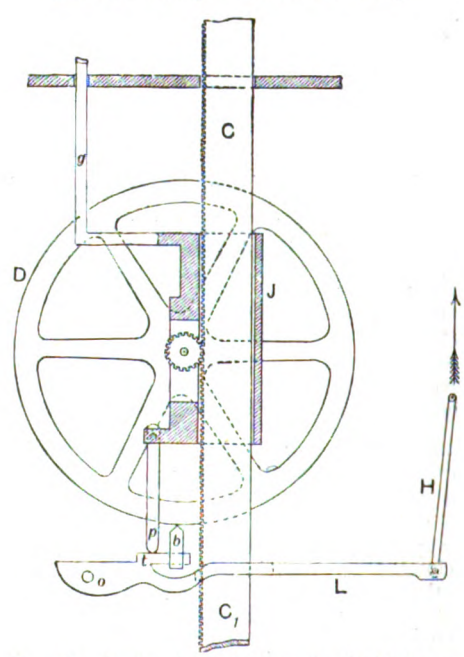

Fig. 19.—Brake-wheel of Crompton-Crabb Lamp.

Digitized by Google

the rim of the brake-wheels and clamps it. Secondly, the wheels being thus prevented from turning, any further rise of the lever lifts the brake-wheel, jockey, and carbon-holder bodily (the weight of them all resting on the break-piece), thus striking the arc. Thirdly, as the arc burns away the lever again descends, until, fourthly, when the tail-piece rests on the table and takes the weight off the break, the feeding begins. There are many other points of interest about this lamp which cannot here be discussed.

Other forms of brake-wheel have been used with success, notably an elastic band-brake, resembling Appold's well-known device, applied outside a smooth wheel, in Statter's lamp (2985[85]).

The most recent form of clutch-wheel is that devised by Alexander Siemens, 6987[87], illustrated in Fig. 20. The lamp to which this device is applied is a holophote lamp for search-lights, with a screw feed, the screw being turned by this clutch wheel. It is about one inch in external diameter, and has a projecting rim, R, within which lies an internal metal ring, B, slightly sprung outwards, and cut obliquely, somewhat in the manner of the elastic metal packing-rings used in engine pistons. The two ends of this internal split ring are joined by two pins to a small lever, L, which projects outwards. When a reciprocating motion, of either large or small range, is imparted to the forked end of this lever, this internal clutch alternately bites against the rim and pushes it forward, and then releases its grip and draws back. This device, which appears to be a really new mechanism, constitutes a true positive feed.

The same device reappears in a recent lamp by Fein (1888) which has a main circuit-magnet striking the arc by drawing down the lower carbon, and a shunt-magnet for feeding, which vibrates an armature by make-and-break arrangement. The upper carbon holder is smooth, of rectangular section, with a smooth feeding roller firmly pressed by a spring against it. This feeding roller is attached to a clutch wheel like Fig. 20. The lamp will work even upside down. Unlike the clutch-wheel devices previously described, Fein's feed is non-retractile. The latest patterns of clutch-wheel feeds are those of Mackie (7184[87]) and Mathis (10740[87].)

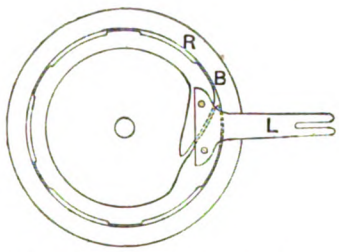

Fig. 20.—Siemen's Clutch-wheel.

The advantages of the clutch-wheel mechanisms over the clutches that act directly on the rods may be summed up by the remark that they render the operation of the lamp independent of dust and dirt.

Of lamps with *screw-feed* motions the most recent are the projector lamp of Siemens (6987[87]) mentioned above, and a motor lamp by Maquaire, which is now being used at the Kensington-court lighting station. In the latter an ingenious and simple method of reversing the motion of the motor armature is adopted, so that both striking and feeding are accomplished by the same screw. This lamp is further described below.

The class of lamps in which cord and pulley mechanism is employed in conjunction with a long-range open solenoid goes back to the early examples of Archerau and Jaspar. In the more complex Pilsen lamp (Krizik and Piette, 1397[80]) two solenoids are used, each with its own coned core, the plungers being connected by cord and pulley, and each bearing one carbon pencil. The arrangement of the circuits of the recent form of lamp is shown in Fig. 21, the core A being drawn into the main-circuit solenoid C to strike the arc, whilst the differentially-wound solenoid P varies its pull on the core B according as the carbons are required to approach, to stand still, or to recede, the former action occurring when the shunt current prevails. The special cut-out mechanism E F will be alluded to later.

A much simpler pattern of lamp has been several times described with various modifications in detail by Jasper, 1878; Romanze (3901[84]), Andrews (3393[82]), and lastly by Menges, 1887, whose form is shown in Fig. 22. Here the long core S N is drawn up into the solenoid, wound differentially with a coarse wire, A, and a fine wire winding, B. A heavy piston of metal on the top of the upper carbon holder *d* serves both to counterpoise the weight of the core and to check, as it slides in the surrounding tubes, any too sudden movements. It is often claimed for solenoid lamps that the absence from them of all mechanism renders them superior to all other species of lamps. Yet they are not free from defects; they do not always burn steadily; some of them have the evil habit of "pumping;" and so simple a matter as the elongation of the cord which connects the plungers may put their regulating properties to confusion. In a recent modification by Doubrava the iron cores are fixed, and the solenoid coils slide up and down over them, giving motion to the carbons.

The *screw-feed* lamps have been already touched on. Of these the most successful in practice is the Cance lamp (3976[81]), which operates by the weight of the upper carbon. The screw is prevented from turning by a nut gripped until feeding is necessary. In Siemens' holophote lamp (6987[87]), and in Maquaire's new lamp, 1889, the mechanical turning of the screw forces the carbons forward.

Amongst *magnetic-clutch* lamps the Gülcher lamp, as improved by the Gülcher Company (Whiteman, 1915[82]), still holds its own. In this lamp the single counterpoised horseshoe electro-magnet—with unequal limbs—sticks itself on by one pole to the iron carbon rod, and by the other pole attracts itself upward to strike the arc. For constant potential work it is a very steady lamp. More recently,

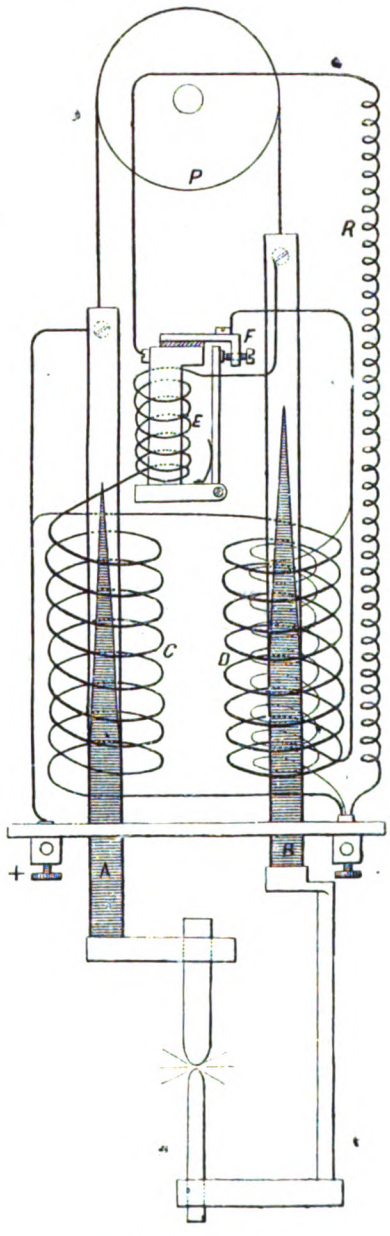

Fig. 21.—Pilsen Lamp.

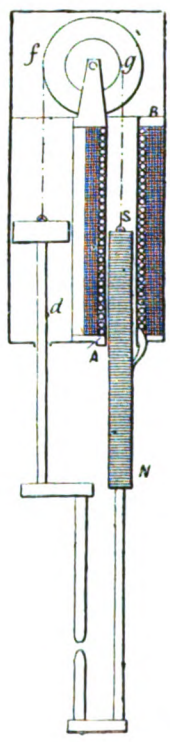

Fig. 22.—Menges Lamp.

magnetic clutch-wheels have been used by Dittmar (1886), and by Trott and Fenton (6910[84]).

Motor lamps have been devised from time to time, those of Tchikoleff, Schuckert, and Gray being perhaps the best until recently. The latest lamp of this type is that of Maquaire (1889). In this lamp there is a Pacinotti ring upon a vertical pivot, on which a worm is cut. This gears into a large wheel, the pinion of which drives the upper carbon holder by a rack. The motor ring stands between the polo-pieces of a powerful electro-magnet. By rotating it in one direction it strikes the arc; by rotating it in the reverse direction it feeds the arc. The direction of its rotation

Digitized by Google

is reversed by reversing the direction of the current in it. This is accomplished in the following ingenious way. The coils of the electromagnet are in the main circuit; and from a point midway along these coils a branch wire goes to one of the brushes of the armature. The other brush is connected to the tongue of a sort of relay, and stands between two contacts, one of which goes to one end, the other to the other end of the coils on the electromagnet. By raising or lowering the tongue the armature is thus connected as a shunt, either to one-half of the magnet coils or to the other, the current in it being in opposite directions in the two cases. The tongue of the relay is controlled by a separate shunt coil, which attracts the tongue in order to feed the arc. The feed action of this lamp is extremely delicate.

(To be continued.)

SPECIFIC INDUCTIVE CAPACITY OF LIQUIDS.

Some interesting researches on the specific inductive capacity of liquids are described in a recent number of Wiedemann's *Annalen*.

Messrs. E. Cohn and L. Arons had previously carried out a series of researches on liquids whose conductivity did not exceed $4{\cdot}5 \times 10^{-13}$ in terms of mercury, and the specific inductive capacity was in every case found to be less than 5, so that the values obtained were of much the same magnitude as in the case of good insulators. The method used by them was founded on the result which they had obtained—that the dielectric polarisation and conduction are mutually independent, and involved observations of the rate of leakage of an electrostatic charge. The present research is concerned with liquids of a much higher conductivity, and a new method had to be devised, as the former one would have involved observations of time-intervals less than a millionth of a second. They therefore used a modification of Silow's method, founded on the principle that when a system of conductors immersed in a homogenous medium is maintained at a constant potential, the work done against electrical forces in producing a definite change in configuration is proportional to the specific inductive capacity of the medium. One terminal of an induction coil was joined to the needle and one pair of quadrants of an electrometer and the second terminal to the other pair. Readings were then taken alternately with air only, and with the given liquid in the electrometer, and in this manner it was found possible to extend the measurements to liquids as high as 16×10^{-10}, or some 3,400 times the highest conductivity to which the former method could be applied. Where K is the specific inductive capacity, and k the conductivity, the author found that for distilled water, for which k varied between $3{\cdot}4 \times 10^{-10}$ and 16×10^{-10}, K retained the constant value of 76. In the case of ethylic alcohol, containing 2 per cent. of water, the value of K was 26·5, which was not sensibly changed by the addition of traces of ammonic chloride, which increased the conductivity by $2{\cdot}3 \times 10^{-10}$ to 12×10^{-10}. When ethylic alcohol was added gradually to pure xylene K and k were both found to increase, but a change of k from 10^{-4} to 0·03 was only accompanied by a change of K from 2·36 to 3·08. These results show that for these substances Maxwell's law expressing the relations between the specific inductive capacity and the index of refraction is not even approximately true, the deviation being much greater than for glass and the fatty oils.

The author points out that it would be of great interest if it were possible to find some law connecting the specific inductive capacity of a substance with its chemical constitution. He suggests that this might possibly be attained by determining the specific inductive capacities of as many well-defined chemical compounds as possible, and of aqueous and alcoholic salts to as high a degree of concentration as possible.

Curiously enough, a Paper is contributed to the same number of the *Annalen* by F. Thomaszewski, in which he endeavours to obtain a solution of the question suggested by Cohn and Arons. The author considers the effect on the specific inductive capacity (1) of the number of atoms in a molecule requiring determinations of the specific inductive capacity of isomeric, homologous, and metameric compounds; (2) of introducing a fresh element into the molecule requiring determination of the specific inductive capacity of non-homologous compounds. These experiments were also carried out by a slight modification of Silow's method.

The values of the specific inductive capacity K, and of the index of refraction for an infinite wave-length μ, were determined for a series of isomeric compounds having the formula $C_{10}H_{16}$, and consisting of oil of citron and of oil of turpentine, obtained from different species of pines; and for a series of homologous compounds, consisting of the aromatic hydrocarbons, benzene, tolnol, paraxylene, and cumene. It was found that K was not constant for the different isomeric compounds, and in the case of the homologous compounds it was found to increase with the number of atoms in the molecule. Maxwell's relation $d = \sqrt{K}$, where d is the density, was found to be only approximately true.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 16th*, 1889.

In my letter last week I made brief reference to the decision which has been rendered in Canada against Mr. Edison by the Commissioner of Agriculture, who also happens to be the Commissioner of Patents of the Dominion. The patent which has just been declared null and void is numbered 10,654, and was granted to Mr. Edison on November 17, 1879, for his incandescent lamp. On November 16, 1881, an extension of three months time within which to manufacture was given to the patentee, on his explanation to the effect that, having been engaged in introducing his invention in other countries, he had failed to manufacture in Canada within the two years prescribed by the law, owing to the large amount of capital that was required to establish the new industry. A petition to break this patent was brought by the Westinghouse, United States, and other interests about a year ago, and in the interval a large amount of evidence has been taken. It appears that on November 14, 1881, the Edison Electric Light Company did start a small factory in Montreal, worked by two men with an outfit worth about £400, and began the manufacture of lamps from the materials imported from the United States. The contention, however, was that the materials used were not raw materials in the rightful sense of the phrase, but were manufactured details of the complete lamp, and were simply assembled in Canada. With regard to this point, some of the witnesses for the defence stated that the carbon filament and the glass bulbs are exceedingly difficult to manufacture, and required great skill and judgment; that they could not be made in Canada; and that in point of fact there was only one factory in the United States itself where those lamps were made satisfactorily. This statement seems to have conflicted with the plea that these various particulars constituted raw material, and such a view of the case seems to have impressed itself upon the Commissioner, who calls the two statements irreconcilable. He says:—"The allegation of inability to manufacture in Canada is no plea in defence of the Canadian patent, and it would be a singular misconception of the spirit of the law if a patentee, probably holding a patent for his invention in the United States or other foreign country, should suppose he could hold to his Canadian patent, declare his inability to manufacture it in Canada, ignore the fact that he was thereby preventing anyone else from engaging in the industry, and defeating the very object and intention of the Patent Act, enacted to encourage and protect home labour and manufacture." The Commissioner further says:—"I find that every essential feature, element, and component part of the invention was, and still continues to be, imported into Canada by the respondents in a manufactured state, for the especial purpose of assembling or putting them together, so as to make them an incandescent electric lamp." On these grounds the Commissioner, therefore, declares the patent void, and he takes the trouble to say, with regard to the other point raised in the case—that of the refusal to sell the lamps except in conjunction with the other details of the Edison system—that even if he had pronounced on that point alone, it is more than probable that he would entertain a view adverse to that contended for by the respondents. It will be seen that this is an important decision with regard to incandescent interests in Canada, and it also appears open to inference that it may have important effects in this country, although this has been denied by the Edison Company. The recent decision of the United States Supreme Court in the Bate refrigerating case appeared to indicate that if a foreign patent should actually expire abroad, its expiration would limit the United States patent. The lifetime of such a United States patent is dependent on the expiration of the foreign patent rather than on the term for which the foreign patent was granted upon its face. Hence the point of the inquiry is shifted to the significance of the word "expiration," and as to whether this would mean a natural dissolution or a violent ending at the hands of the Court. It looks as though the Supreme Court would have to interpret its views a

Digitized by Google

little more fully for the benefit of patent lawyers and an anxious public.

You will remember that I made the remark that although we were well through the first quarter of the year, nothing had yet been done with regard to carrying out the law inflicting sentence of execution by electricity in capital cases. This omission appears to have attracted attention, however, and during the present week we have had another series of experiments carried on by the indefatigable Mr. Harold P. Brown as to the effect of electricity on animals. In this instance the experiments of Mr. Brown, which were again made at the Edison Laboratory, were witnessed by some of the State officials. The animals experimented upon were dogs, calves, and horses. Nothing but the alternating current was used, and with it the dogs gave up the ghost at 500 volts, the calves at 800, and the horse at 1,000, after 25 seconds exposure. The law provides for the setting up of electrical apparatus for execution purposes in each of the three State prisons in New York State. As there are on the average not more than eight executions a year in the whole State, it is thought by some that this is rather an extravagant allowance, and it is urged that the apparatus should be kept in one place only, in some central location, not necessarily a prison. It is also urged that the apparatus, which it seems now pretty well settled, will be of the alternating character, should be placed in charge of a thoroughly competent electrician, for after all there is a very widespread feeling that this method must be applied with the utmost nicety and care. It is not yet known who is likely to secure the post, but in some circles it is expected that Mr. Harold P. Brown himself will be named as Lord High Executioner.

It is rather a striking commentary upon the legislation proposed in various States against the telephone companies that the law which was passed two or three years ago in Indiana, cutting down telephone rates has just been repealed. At the time of the passage of the Indiana law there was a very strong and bitter feeling in various parts of the State against the telephone companies. Their wires were ruthlessly cut in many places, their poles were chopped down, and they were ordered either to do business at a loss or to get out. They adopted the latter alternative, and the State was practically without a telephone service. The inconvenience soon began to be felt, for, after the telephone has been installed any length of time, its use becomes second nature, and its advantages are accepted almost as a matter of course. An interruption of the service, however, emphasises in a peculiar way its many advantages, and thus it happens that no sooner had the Hoosiers decided to do without the telephone than they began to want it back again. It is very much to be doubted whether the anti-telephone movement was strictly a popular one. It seems rather to have been worked up at first as a method of blackmailing the telephone companies, and having failed in that purpose, to have been used as a weapon of revenge. However, as might be expected, the good sense and intelligence of the people at last governed the situation, and there is every prospect that the telephone will soon resume its position in Indiana as one of the necessary comforts of life. It is to be feared, however, that this object lesson will be lost on many of our legislators, for in Illinois agitators have just succeeded in legislating for lower rates, and in New York the movement is still on foot, although the Hamilton Telephone Bill has been amended so as to fix the charge for New York City at $100 a-year. The rest of the State, however, is not affected by this amendment, but there is a saving clause to the effect that the telephone companies may make contracts for special work and for special service.

Boston has just been the scene of a very interesting discussion on the safety, economy, &c., of overhead wire systems for electric railways. This discussion was held before the Railway Committee of the Massachusetts Legislature, and arose out of a hearing relative to a measure granting permission to the West End Railway Company of Boston to run overhead electric railway conductors through the streets of Boston and elsewhere. It is understood that should the company obtain the consent it seeks, Boston will soon have over 200 miles of overhead electric railway system. It was natural that those interested in storage batteries and conduit systems would not be willing to allow so big a prize as Boston to slip through their fingers, and hence several of them appeared before the committee and made objections to the disadvantages of the overhead system as compared with the storage battery and the conduit. Mr. William Bracken, president of the Julien Company of this city, whose storage cars are running in New York, called attention to the work which is being done here, and insisted on the preferability of the storage car. He was supported by Mr. Ries, Dr. Vander Weyde and others, as well as by counsel representing remonstrant property owners, and was opposed by Prof. Elihu Thomson, Mr. C. J. H. Woodbury, Capt. Griffin, U.S.A., and others, who testified as to the general success of the overhead system, and as to the fact that the potential of 500 volts used so universally on that class of work is not at all one dangerous to life. There is said to be a likelihood that the West End Railway Company, which has been fighting for its case with a great deal of ability and energy, will get the permission it seeks; but it seems certain that no such comprehensive scheme of overhead electric railway conductors will be tolerated in New York, where the conduit system and the storage battery will have it all their own way unless they are forestalled by the cumbrous cable system. This remark does not, of course, include the elevated railroads, for we still have hopes of capturing these, and Mr. Daft is hanging on to the Ninth Avenue-road with a dogged tenacity worthy his British blood.

"The Efficiency of Methods of Artificial Illumination" was the title of a most able and interesting Paper read by Prof. F. L. Nichols, of Cornell University, before the American Institute of Electrical Engineers at its last meeting. In this Paper Prof. Nichols has taken up the subject of the light-giving value of different methods of illumination, and especially the incandescent lamp, with the object of determining the ratio of the light given to the total energy developed. In determining the relation between the luminous radiation and the total radiation of the incandescent lamp, Prof. Nichols cited the experiments of Merritt, who has determined these quantities in two different ways—in the one case by means of a glass calorimeter, in which the increase in the temperature of flowing water measured the heat developed, and in the other case by means of a thermopile which measured the heat radiated directly. The conclusions arrived at by Prof. Nichols would seem to indicate that the disparity heretofore supposed to exist between light-giving value and total energy between the arc lamp and the incandescent is not so great as was supposed when we consider the mean spherical intensity of illumination, although, when measured in certain positions this ratio may be as high as 6 to 1 in favour of the arc lamp; yet, considering the total illumination in all directions, that ratio hardly exceeds 2 to 1.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *March 26th*, 1889.

The erection of the Vienna-Prag telephone trunk line, and the decision to erect a telephone trunk line from Vienna to Budapest, has stirred up other towns to try and get the Government to erect similar lines to their towns. A deputation, consisting of the burgomaster and some delegates of the Chamber of Commerce of Pilsen, waited on the Ministry of Commerce, and asked that a trunk line be run from Vienna to Pilsen, at least from Pilsen to Prag. They were informed that the Government could not do this this year, but would take the matter into their serious consideration next year. The Chambers of Commerce in Trieste and Fiume have also petitioned that a trunk line be run from Trieste, the only Austrian large commercial port, to Fiume, the Hungarian port. Both the petitions from Pilsen and Trieste were supported by the Telephone Company of Austria, who have exchanges in these towns. The Government also propose running a short experimental line over one of the worst parts of the Karst, a bare mountain region between Laibach and Trieste. This line is to be built of silicium bronze wire, and specially constructed to resist the snow and ice, which in that part have hitherto devastated the telegraph lines every year. Should this line stand the winter there, the idea of connecting Trieste with Graz and Vienna will probably be realised.

The Austrian telegraph service enjoys a special reputation for building good overland lines, and they are doing their utmost to so

Digitized by Google

construct the new line to Prag that no defects should crop up. Much thought and care has been bestowed on the joints, and the joint adopted is really the most perfect I have seen. The poles have been carefully selected, and the way the wires are to be crossed is as simple as it is ingenious. I hope at some future date to to able to send you a description of these crossings.

CORRESPONDENCE.

THE FRITSCHE DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your "Notes from Germany," *Electrician*, March 8, 1889, you mention a new dynamo made by Fritsche and Pischon, of Berlin. Please allow me to say that this machine is a direct infringement of our patents. In *The Electrician* of June 10, 1887, a full description of our Faraday disc machine was given, and in which the vital principles were described, viz.:—

"It will be seen from this construction that every coil has the same area, and each and every coil is so divided that one-half is in the inside of its neighbouring turn while its other half is on the outside of this neighbouring turn; also, that one-half of every turn is on one side of the armature while its other half is on the other side. It must be understood that this construction is not a simple overlapping of coils, which would cause an oblique or sloping position, but is a mode by which each half of the coil lies in a different yet parallel plane.

As is known, we make our coils out of metallic strips or bars, as is shown in *The Electrician*, June 10, 1887, Figs. 2, 3, 5, 7. It can easily be seen that it makes no difference if instead of taking a strip or bar, as we do, and dividing it into two parts, as shown in the above-mentioned figures, we take two parts and solder them together to make the same piece, which could have been made direct. We have seen the German patent of Fritsche, No. 45,808, and it contains only one meagre claim for a winding, which in reality is nothing but a zigzag winding, and which zigzag winding we also use in our machines, and which is also shown in *The Electrician* of June 10, 1887, Fig. 10.

You will remember that we sent you about a year or so ago a monograph of our iron Faraday, in which the armature is entirely made of iron. Such a monograph was also sent last year to Siemens, of Berlin.

We therefore invite Messrs. Fritsche and Pischon to show where the new idea of their machines comes in, and where there is not a direct infringement of our rights.—Yours, &c.,

JEHL AND RUPP.

Am Kiosk 7, Brünn, March 21, 1889.

THE CENTRAL LIGHTING STATIONS OF FRANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have read in the issue of 15th inst. of your esteemed journal a list of Central Lighting Stations of France, compiled from a Paper read by Mr. Aimé Witz and enlarged and revised by your Paris correspondent; but to our great surprise we find that both Mr. Witz and your correspondent have neglected to complete that list by mentioning the central lighting stations made by our licensees in France with Zipernowsky-Deri-Blathy alternating current-transformers, and we therefore take the liberty of giving you the following specification relating to the said plants:—

Towns.	Output in lamps.	Distribution.
Reims	300	Overhead.
St. Tropez	200	,,
Rives	300	,,
Valréas and Dieulefit	600	,,
Dijon	900	,,
Grenoble	900	,,

The central station for the lighting of the two towns of Valréas and Dieulefit is erected at Become,—Yours, &c.,

Budapest, March 19, 1889. GANZ ÉS TÁRSA.

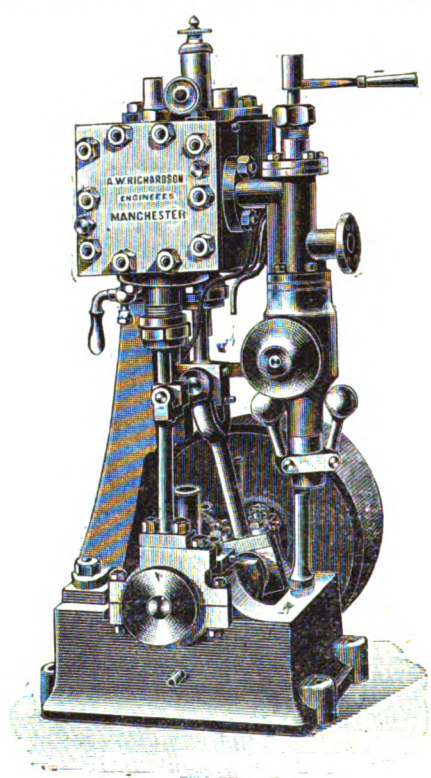
THE RICHARDSON HIGH-SPEED ENGINE.

This engine, as illustrated, has been specially designed for dynamo driving direct, or by belt or ropes. It is also adopted for driving centrifugal pumps, fans for forced draught, and for any purpose where great power and high speed are required in a small space. It has been constructed with great care to run at high speeds with safety and economy, and without excessive wear. The crank is made of mild steel, carefully balanced. The cylinder and upright are cast in one piece. The cylinder is steam-jacketted, and is fitted with a liner, which with the valve face can be at any time removed.



The piston rings and valve are of phosphor bronze. All bearings are extra long, and are made of phosphor bronze or best gun-metal. The crank shaft bearings are fitted in square, with wrought-iron caps. The glands are specially constructed for tightening whilst running without the risk of jamming on the rods. The governor is of the high-speed class, and is very sensitive, and can be adjusted whilst running. All forged parts, bolts, studs, and nuts, are made of mild steel. All parts are made to template, and are interchangeable. The lubricating arrangement is well adapted for long and continuous running. The most practical way of driving dynamos on steamships and other confined spaces is by small high-speed engines coupled direct. These engines take up little room, as they can be fixed on the same bedplate as the dynamo. They are made inverted and horizontal, double and compound, in sizes from 4½ to 60 indicated horse-power. Engines of this class can be fitted with automatic expansion arrangement if required. The maker is Mr A. W. Richardson, of Stretford-road, Manchester.

COMPANIES' MEETINGS & REPORTS.

Direct Spanish Telegraph Company (Limited).

The thirty-first ordinary general meeting of the Company was held at Winchester House, Old Broad-street, on the 25th inst., under the presidency of Sir James Anderson.

The MANAGER (Mr. Charles Gerhardi) read the notice convening the meeting, and the minutes of the last meeting having been read, were signed by the Chairman as correctly entered. The report of the Directors was taken as read.

The CHAIRMAN: I have very little to say on this occasion. Curiously enough, as I sat in the adjoining committee room three minutes ago, I looked over what I said at our last half-yearly meeting, and to my no little surprise I found that I had used almost the very same words that I was going to say to this meeting. I said at that meeting:—"We have carried 2,000 more messages in the last three months than in the corresponding three months of 1887; but we had not earned so much money." I was going to say to you now that we have carried 2,000 more messages in the half-year under review but 27,000 fewer words than in the corresponding half year of 1887. The average length of the telegrams has fallen about three-quarters of a word. We are face to face with a natural desire of all merchants to economise all the money they can, and to make their telegrams as short as possible. I do not know what they are going to come to, but it is quite obvious that if they go on reducing the length of the messages to, say, only one text word, it will be impossible to pay anything. I find on investigation that there are an enormous number of telegrams sent to the East consisting of three or four words only, and a three-word message does not pay at all. Whether anything will be done to alter that at the conferences I cannot say, but it is remarkable that whenever I come before you I have to say the same thing—that the messages are getting shorter and shorter, and that while we are carrying more of them we are getting no more money. There is a decrease of

Digitized by Google

£305 in the traffic receipts compared with those for the corresponding period of the previous year. That, however, is not owing to a falling off in trade generally, but through the failure of the fruit trade. This year the fruit was as bad as it could be, and it nearly all went rotten at sea. Formerly this would have been a more serious matter with us, because a few years ago the telegrams were all about fruit and shipping, but now, since the Commercial Treaty was framed, we have a more miscellaneous class of messages. You see by the report that we have had a break in our Bilbao cable since the date to which the report refers. Fortunately for this Company, the Eastern Telegraph Company had a ship at Lisbon, and she was able to get on the ground in three days from the time the break occurred, and, although the weather was very bad, she effected the repairs in sixteen days, curiously enough the time it took to repair the former break. I have on the table a piece of the broken cable. It was down 1,£00 fathoms, and you will see that it was literally torn asunder by a landslip. Evidently a mountain of mud fell down and wrenched the cable in two. I do not know how we are to avoid these sort of breaks. We have had them again and again in various parts of the world, and we cannot find any way of getting over them except by repairing them. The cost of these late repairs was £2,966, and we deal with that by carrying forward £723 out of revenue this time, and you will pay the balance partly out of revenue and partly out of reserve next year unless we have another break next time, though I have no reason to apprehend anything of the kind. I am glad to be able to tell you that in spite of the sixteen days' interruption—in consequence of which we lost some of the traffic, though not all, because we have a joint-purse arrangement with the Eastern Telegraph Company—we have earned £250 more this quarter than we earned in the corresponding period of 1888. I have nothing more to say unless you ask questions to which I can reply. We are going on successfully, and Mr. Gerhardi and all our officers are doing their best to foster and increase the traffic by visiting the stations and the provinces, and at the present moment we are doing as well as we can very well expect. With these remarks I beg to move—

"*That the report and accounts now presented be and the same are hereby received and adopted.*"

Mr. EDMUND ETLINGER seconded the motion, which was carried unanimously.

The CHAIRMAN: I now propose—

"*That the dividend at the rate of 10 per cent. per annum less income tax on the Preference Shares, and a dividend at the rate of 4 per cent. per annum free of income tax on the Ordinary Shares, both for the half-year ended December 31st, 1888, be and are hereby declared.*"

Mr. ETLINGER seconded the motion, which was carried unanimously.

Continuing, Mr. ETLINGER said: The next resolution refers to the re-election of retiring Directors, and I have very great pleasure in proposing the re-appointment of Sir James Anderson. That is a motion which hardly requires any further remarks from me.

Mr. JOHN DENISON PENDER seconded the motion, which was carried unanimously.

The CHAIRMAN: I am obliged to you for your confidence. I am very glad that we are in the saddle, because it is a great matter for us to be able to use the ships of the Eastern Telegraph Company and of all the other companies with which we are connected. That saves us a good deal of money. I have now the pleasure of proposing the re-election of Mr. Denison Pender.

Mr. ETLINGER seconded the resolution, which was carried unanimously.

Mr. PENDER having acknowledged his re-election,

Mr. JOHN GLOVER proposed, and Mr. W. B. COCHRAN seconded, the re-election of the auditor, Mr. Herbert R. Duke, which was unanimously carried.

Mr. COCHRAN: Are you quite satisfied with the character of the Bilbao cable?

The CHAIRMAN: Yes; nothing stronger could be made in the world.

On the motion of Mr. COCHRAN, seconded by Mr. JOHN NEWTON, a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN: Though we have not much to say at these meetings, we give a great deal of anxious thought to your affairs and in devising what we can do to economise and to increase the traffic. I think it most fortunate that Mr. Gerhardi and I came together five or six years ago and resolved on a joint-purse agreement, which has made it better for us all round.

The meeting then separated.

The Submarine Telegraph Company (Limited).

An extraordinary general meeting of this Company was held on Monday at the offices of the Company, 2, Throgmorton-avenue, London-wall, for the purpose of considering the offer of the French and English Governments to purchase the Company's cables between England and the Continent. Sir Julian Goldsmid, Bart., M.P., presided.

The SECRETARY (Mr. S. M. Clare) having read the notice calling the meeting,

The CHAIRMAN said: Ladies and gentlemen, I am afraid that I shall have to trouble you at considerable length in order to give you a full account of the state of affairs with which we have at present to deal, and as I am suffering from great hoarseness I am sure you will give to me your indulgence. I must take you back to the 16th of July, 1878, the date at which we made an agreement with Lord John Manners, who was then Postmaster-General. That agreement, besides providing for giving the proportions to the Post Office of the receipts which came in from the telegraphic communication with the Continent, also contained a very important clause, which has been mentioned to you before, but on the present occasion I consider it necessary that you should have the whole case before you, in order that you may arrive at a satisfactory conclusion, and therefore I will read the clause now. It is Clause 8 of the agreement, and is as follows:—"This agreement shall take effect from the 1st of January, 1879, or so soon after that date as the French and Belgian Governments shall have granted a renewal of the concession to be applied for, and shall remain in force until the 31st December, 1898; but no alteration of the existing tariff shall take place unless and until this agreement shall come into operation." Well, that was signed and sealed on the 16th of July, 1878.

A SHAREHOLDER: At what date does it expire?

The CHAIRMAN: If it had come into force it would have gone up to 1898, but as it has never come into force the only part that is material is the date at which it was made. My predecessor, the late Sir James Carmichael, forthwith made application to the French Government, which was always considered the leading Government with regard to the arrangement between the Post Office and the Submarine Telegraph Company, to give them a renewal or extension of the concession which, as you know, expired early this year. The French Government upon that occasion and in three subsequent years absolutely refused to do so, because, they said, the application was premature. They said that the time which had still to elapse before the end of the concession was too long, and they therefore declined to consider the question. So matters went on until three years ago, when I thought I would make a determined effort to obtain a renewal of this concession in order to put this agreement which I have read to you—which was practically a draft agreement—into force. Without going through all the events of those three years, I may say that we negotiated with four successive Ministries, and that practically three of them nearly came to a conclusion. The last Ministry of all with which we negotiated was the Ministry of which M. Rouvier was the head, and he was particularly capable of considering this question, because he had attached to his own department of Finance the Telegraph and Post Office Department, which had been previously a separate one, with a separate and independent Minister. The result of the efforts made by many of the Directors was this: M. Rouvier informed us in writing that he was prepared to grant a renewal of the concession for 10 years, and then occurred what has also been mentioned to you—a diplomatic Note on the part of Her Majesty's Government, in which they requested the French Government not to grant a renewal of that concession. Well, we maintain that under the agreement with Lord John Manners they had no right to do so, but their argument was that as a reasonable time had elapsed since the signing of that agreement, and no renewal of the concession had been obtained under this Section 8 to which I have referred you, they were no longer bound by an agreement which had not been put in force. The policy of the Government had changed, and they had, therefore, determined to make arrangements with Foreign Governments by which all the telegraphic communication between England and France, England and Belgium, England and Holland, and England and Germany, should be in the hands of the respective Governments. We thought that, considering that agreement very hard upon the proprietors of the Submarine Telegraph Company, who had been led to believe, as we had been led to believe, that we should in all probability obtain a renewal of the concession, and I have pointed out to you as clearly as I can the reason why we considered we had a right to expect a renewal of the concessions if the French Government and the Belgian Government were willing so to renew them. But the position at this date eighteen months ago was practically this:—We had obtained this promise of renewal, and that promise was about to be carried into effect when the English Government prevented its being carried into effect. Then they made arrangements with the French Government by which they should jointly acquire the cables between France and England, and Belgium and England, and they also made arrangements with the German Government by which one cable which belonged to England should remain in the hands of England, so that there again the communication between Germany and England should be divided between the two countries. That leads me to a point with regard to the German Union Telegraph Company. That company had a concession which was not an exclusive concession, and there were still, I think, about eleven or twelve years of it to run. That concession not having been exclusive, it would have been possible for the German Government to lay down other lines, or to make arrangements in some other way with the German Union Telegraph Company. As they decided that it was desirable to take the telegraphic communication into their own hands, they gave notice to the German Union Telegraph Company, and the result of that was that they came to an agreement with the Directors of that company by which they refunded the capital of the Company, with a bonus of 25 per cent. upon it. In some of the communications that we have had with the Government we have pointed to that as an example that might be fairly followed in the case of this Company; but they did not appear to see the argument exactly in the same light in which we saw it. Then came the question what was to be done at the end of our present concession. We had frequent interviews with Her Majesty's Government, who were authorised and requested by the French Government to carry on negotiations with us on behalf of the Governments concerned, and the sum and substance of the proposals made by the Chancellor of the Exchequer and Mr. Jackson, Secretary of the Treasury, on behalf of the Government, was this originally, it was that we should sell to them the French and Belgian cables at a valuation price, the valuers being appointed one by the Governments, one by us, and an arbitrator in the usual manner. That was a proposal which is well known to everybody connected with English law, and which is in itself so fair, was one which recommended itself to us for which we were prepared to accept, and that was perhaps the very first point on which we easily came to an agreement, and which we understood to be settled and done with. Then you can imagine our surprise when only about three months ago we were informed that the French Government had decided that they would have nothing to do with this

Digitized by Google

method of valuation, and that they must have some other system adopted, which other system we fear will be less satisfactory to the shareholders of this Company, and less fair from our point of view. After negotiations, which were again of a protracted and troublesome character, it was finally decided that the Governments were to appoint officers to test the cables to ascertain exactly their electrical condition, and that they should make an offer based upon the results at which they had arrived in consequence of that test. Well, they set officers to work, and the French officers applied to the cables tests which, I think I may fairly say, were not such as should have been applied, and such as are only applied in the case of cables in the course of manufacture in the laboratory, and not to cables which have already been working for some period of time at the bottom of the ocean. Our contention has always been that the value of a cable as a commercial investment is its practical efficiency. On that point I think I ought to say a word or two, because allegations have been made with regard to the condition of the cables which very seriously affect the question. You must be aware that the cable which is at the bottom of the Channel is not in the same position absolutely or relatively as a cable that is at the bottom of the Atlantic, or any other deep ocean, because it is liable to fracture and danger by the anchors of fishing boats and in many other ways, to which cables at the bottom of a deep sea are not liable. The fact is notorious. For example, on one occasion a fishing boat in stormy weather brought up with its anchor one of our cables, and being in a hurry to get away the skipper did not take the trouble to unfasten the coil round his anchor but chopped it in two. Then, of course, the two ends sank to the bottom of the sea. The result of that was to proceed to mend the cut ends. It is not always easy to find the authors of such a proceeding. That, therefore, shows the point to which I wish to come, which is that a cable, however good, must be repaired frequently when it is at the bottom of the Channel, whereas if it is at the bottom of the ocean it may be quite undisturbed, and the result of that is that no cable is entirely free from constant repair. During the last decade—or rather during the last five years—the cables have not been repaired so frequently as they had to be during the previous period of ten years, but taking the same relative proportions during the last five years, the cables appear to have been more free from accident than they did at the two previous periods of the five years. It is a curious circumstance, and shows that age has nothing to do with it, but that accident has much to account for. The result of the testing of the cables was this, that allegations were made that these were patched cables, which of course I have explained must of necessity be the case, and that, in addition, the officers did not consider that those cables were in an electrically perfect condition. We have pointed out that as far as the cables are concerned they practically do the work very well without any impediment to traffic, and consequently they are in a perfect condition from a business point of view. Anyhow, the result of that proceeding has been that we have had two letters, which I shall now call upon the Secretary to read, and then I shall proceed with my statement, and give you the rest of the information upon which you will have to give your opinion.

The SECRETARY here read the letters addressed to the Company by the authorities of the Post Office with respect to the conclusions which the Governments of France and England had arrived at as to the value of the Company's cables.

The CHAIRMAN, commenting upon the various letters, said: Those letters were immediately brought before the Board, and we considered the matter of such importance to the shareholders of this Company that we decided to immediately call a meeting of the chartered Company and a meeting of the shareholders of the French Company, in order that we might lay the whole of the business before them, and I forthwith informed the Chancellor of the Exchequer that that was the case, and that we had fixed on the earliest date to hold such meetings, and that until those meetings we could not give a definite reply, and that therefore we must ask the Governments to be good enough to extend the time for settling matters in order to lay them before the proprietors. You will expect from me some information with regard to the value of cables calculated to do the business which has to be done and has been done by the cables in question. There are four cables belonging to this Company which are now at work between England and France. If you had to lay down four new cables over the same areas Mr. Clare's estimate is that they would cost the sum of £59,385, and the cost of two new cables to Belgium over the same lines would be £33,678, so that those six cables would cost £93,073. Now, the Government offered for the four French cables, first, £11,300 and 10 per cent. added, making £12,430, and for the two Belgian cables £9,000, with £900 added, making £9,900, and the total of these sums would be therefore £22,330, or, as you will see, 25 per cent. of the actual cost of new cables. With regard to the six cables belonging to this Company with which we have to deal, there is therefore an offer of £22,300 on behalf of the Governments. I have to say that, as the result of an interview that several of us had with the Chancellor of the Exchequer, he has authorised me to say that any sum that was finally agreed upon to be paid would be handed over by the English Government direct, and that they would afterwards arrange with the French Government. Then I wish to point out to you that the cost of new cables is four times as much as the price that is offered to us for these old cables. We have always calculated that under the worst terms of a valuation by arbitration, to which reference was made by me in an early part of my speech, and which was originally agreed to by the Government, would have given us at least 50 per cent. of the cost of new cables; and some of us thought that the sum given us would reach 75 per cent. Consequently you will see that from that point of view we are offered a very small proportion of the value of new cables. Well, now, I ought also to put before you another aspect of the question, which is not, of course, quite so important, but which, I think, ought to be communicated to you. The French cables really earned in the past half-year about £28,900, and the Belgian cables earned about £11,930, making altogether £40,830, and if we take off £17,000, roughly, for working expenses, we are left with a net income of £23,830. You will therefore see that in six months the net income of the cables is a little more than the price offered to us for the means of earning it. Therefore, from that point of view the Government would certainly be making a very good bargain. The question then arises—Ought we to accept this offer or ought we to reject it? If we accept it what will happen? If we reject it what will happen? Upon this point I ought to say that if there has ever been a difference of opinion between myself and any of my colleagues I believe it has been more as to the advice that we should give to you on this matter than on anything else, and I think you will understand that we have found ourselves in a most difficult and more embarrassing position. I have had much business to transact in the course of twenty-five years during which I have been connected with companies, but I have never had so much trouble or anything which has given me so much anxiety as the negotiations with regard to these matters, which have been attended to by myself and every one of my colleagues, I will venture to say, as if they personally concerned ourselves rather than if they concerned a body of shareholders. I may say that on behalf of my colleagues as well as on my own we have done everything that we could in any way to promote the interests of the shareholders. If we have to lay this unsatisfactory state of affairs before you I assure you it is not owing to any lapses on our part, but owing to the inherent circumstances of the case over which we have no control. We are asked to take for those cables a sum which we certainly consider to be considerably below their value. Then there are left to us two other cables which are part of our property, namely, the cable which is leased by the Paris and New York Telegraph Company, and which, under the agreement, we have every reason to believe that they will purchase at a sum of about £11,000; and then we have another cable leased by the Anglo-American Company; but I do not wish to say anything further with regard to these two cables. What I am referring to is the offer of the Government for the cables with which we have now to deal—the four to France and the two to Belgium. If we decline the offer made to us, I must put before you what, in my opinion, is the position of affairs. We are told that the French Government are anxious to lay down altogether new cables, and that in their opinion they think it would be better to begin business by doing so and not by purchasing our cables. Of course, in that case, at the lowest valuation—and our estimates are low and reasonable—the French authorities would have to spend their share of some £60,000, instead of paying only the very small sum which is offered to us; but they would have new cables instead of our cables, which we believe to be perfect instruments for many years to come. I have pointed out to you that new cables may be broken as well as old ones. Now, then, there is this chance, that if you refuse this offer that the two Governments may say that they won't have our cables at all. In that case of course the cables would be worth only their picking-up value, whatever that might be. That is a very serious consideration, which the shareholders must carefully weigh. You may fairly ask us at this point, have we done our best and our last in order to induce the Government to consider whether they cannot make us an offer more adequate, more suitable to the occasion, because we have pointed out to them that they are obtaining an instrument by which they will earn an income for the country which is known in no other Government investment, and which ought, therefore, to allow them to deal, I will not say liberally, but justly, with the shareholders of this Company? We have done our very best in this direction, and some of us flatter ourselves that we have produced some slight impression upon the heart of the Chancellor of the Exchequer, which may be stony, but which I cannot help hoping in this case may not be so. My colleagues and I have urged upon him to really examine these points, which I have ventured to put before you in as clear a manner as lies in my power, in order that he may see that we are not getting a reasonable price for our property. Though I have no right to say so, I have still some hope that there may be an improvement in the offer made; and, consequently, if you ask me what you had better do under all the difficulties of the situation I should advise you to pass something of this kind, which I have carefully considered, and which I believe meets the best view of the circumstances of the case. It is this:—"That the Directors be requested to inform the Government that, in the opinion of the shareholders, their offer of £22,330 for the purchase of the Company's cables between England and France, England and Belgium, and Jersey and France, is far below their value; that the Directors be authorised to allow the Government to work the cables on and after the 1st of April next, to continue their negotiations, and to conclude the sale of the cables to the Government at the best price they can obtain, and that the Directors inform the proprietors by circular, as soon as possible, of the result of their further negotiations." Why I ask you to give us this authority is, as I said just now, that I hope that the Chancellor of the Exchequer will be persuaded to point out to the French Government that they ought to give us something more than the amount referred to. But, in my opinion, and in that of the majority of my colleagues, it is desirable that you should authorise us to conclude this matter in order to avoid greater risks and greater dangers which might fall upon you. The latter part of the motion has reference to allowing the Government to work the cables on and after the 1st of April next. One of the conditions that the Government proposed was this, that they should have the right to come into these premises, take over our staff and the work, and they offered and agreed to give us 4 per cent. upon the amount which they may have to pay us up to the date at which they pay us. I may say that the Government of England are taking over a great deal of property which does not concern the Government of France in any way. They are going to take this house, all our stores, our steamboat, our country places—I mean our stations where we have the landings of our cables—in fact, they are going to take over everything used for the working of the business, and, what is the most important thing of all, they are going to take our staff with very few exceptions. With regard to the staff, which is a matter which greatly concerns the

Digitized by Google

shareholders—and, I think I may say with some pride, that the best relations have always existed between the staff and the Directors who have represented the shareholders—I think the staff have been of opinion that the Directors have endeavoured to look after their interests as well as those of the shareholders; and I believe that a good state of feeling between the staff and the Directors representing the shareholders is the very best and only condition which ought to exist in a company like this—in looking after the interests of the staff we have been very anxious that no man, if possible, should lose his berth. We thought that the shareholders would be of that opinion, and the result of our negotiations has been that with some exceptions the whole of the staff will be taken over by the Government. Then we naturally asked, What will you do with those of the staff that will not be taken over? Mr. Clare is one of these, and a few others. After some discussion they agreed to give two years' salary as a bonus to each of the officers who did not pass over to the service of the Government provided that the amount so paid did not exceed £5,000. We made a representation to the Government the other day that the officers who have to retire would require a sum of something like £5,800 in order to receive their two years' salary, to which they would under this arrangement be entitled, and we asked the Government to extend their proposal to that amount. They have extended it to £5,500, but they said no further, and consequently I shall have to ask you to give us the other £300, or to authorise us to pay it out of the funds of the Company, and I am quite sure the shareholders will say that this allowance should be made to the officers who will not be taken over by the Government. That is the exact position of affairs. I have now to give you a little information with regard to the Calais cables which belongs to the French Company. That was the original cable which did business between England and France, and according to the tests of the French officials that was the best cable of all, thereby contradicting that allegation that it is age which incapacitates a cable from doing its work, and confirming very largely the statements which I have made on several occasions, that the value of a cable between England and France does not depend upon its age so much as upon the absence of interruptions to which it may be subjected by ill-treatment. It is like everything else—a question of treatment. Therefore, the Government say that they are willing to give more in proportion for that cable than for any of the others. That matter will have to be considered by the French Company on Saturday next, but the course you will adopt to-day will mainly guide the French Company in what they should do, and consequently your decision is of great value and importance from that point of view. I will sum up the position in this way. You are offered the sum of £22,330, to take or to leave it, unless we can induce the Government somewhat to improve that offer, as we have still hopes of doing: and I suggest to you that you should give us authority to conclude the matter even for that miserable sum, if it is absolutely necessary, and I put it on the ground of fairness and justice, and of the value of the property as an income-earning machine, to the Government that they ought to give us more. That is the exact position of affairs, and I shall either move this resolution myself if you think it is desirable that I shall do so, or I shall ask some shareholder to move it in order that it may be before you for your acceptance or refusal. If the shareholders reject it it will devolve upon them to decide what course we shall follow under the very difficult circumstances of the case.

A SHAREHOLDER seconded the resolution.

Mr. ROBINSON said that he was very much surprised when he received the notice of the meeting that the Board did not inform the proprietors of the amount which the Government offered. He was sure that all the shareholders were very much astonished at the ridiculously low sum which was offered to the Company. He would also like to ask what position they would be in if they refused to carry the Government messages. Could they not put the screw upon them and put them to very great inconvenience by refusing to carry their messages after the 1st of April? After the way in which the Company had met the wishes of the Government in times past they ought to have met the Company in a more liberal spirit.

Mr. RAINES asked what would be the picking-up value of the cables, supposing the Company refused the offer of the Government, and also whether the Company's other property was to be valued on the same scale as the offer for the cables.

The Hon. H. R. BRAND, in reply, said that the answer to the first questioner must be obvious, that the Company had a duty to the public as well as to the Government, and that it would be most fatal to their interests to place themselves in a position so invidious as that suggested applause. The Chairman had already told them that it would cost about £93,000 to lay new cables, and that they were offered £22,330, while they would have considered that the price offered to them would not have been unreasonable if they had obtained for their cables 50 per cent. of the value of new ones: therefore the sum in question was somewhere about £25,000. He did not think that it would pay the cost to pick up the cables.

Mr. LEWIS suggested that it might be *ultra vires* to enter into any bargain such as that proposed without first consulting Parliament.

Mr. SODEN, while admitting the difficulty of the situation, thought that the Board had shown some weakness in their negotiations. His own opinion about the action of the Government was that it was an act of spoliation. £22,300 was not 1s. 4d. in the pound of their capital of £338,000. He would like to known what was the bargain that the Government were making with the French authorities. He was inclined to think that it was an improvident one. He twitted the Chancellor of the Exchequer for following a course in this transaction diametrically opposed to the course he advocated under similar conditions in the year 1868. He thought that the whole question ought to be submitted to the arbitrament of Parliament and the nation before they accepted the miserable proposal of the Government. He concluded by proposing as an amendment,

"*That the meeting be adjourned until Thursday, to give the proprietors an opportunity of further considering the matter.*"

Mr. LEWIS seconded the amendment.

Mr. KING denounced the action of the Government as a piece of abominable shabbiness, considering what the Company had done as the pioneers of submarine telegraphic enterprise. They had a right to expect at least he would not say generous treatment but decent liberality.

The CHAIRMAN said that their rights expired on the 12th of January of this year, and if they had no landing rights for their cables they could not carry on telegraphic communication. By arrangement they had secured one thing for the shareholders—they had secured an extension of the concession up to the 31st of the present month. But the Government had informed him that they did not mean to extend it any longer. The Government had undertaken to purchase their premises, to take over their steamships, stores, &c., at an arbitration price, and if they refused the offer for the cables they must see that they would be imperilling the rest of the arrangement. In his opinion that arrangement with regard to the rest of the property was a fair and reasonable one. They had had for several years a rate of interest which had been very high, and it had recouped them for their big outlay, which was the answer that the Government had given him. If he were, in his private capacity as a Member of Parliament, to bring this question before the House of Commons, the answer would be that he was looking after not the interests of the country but the pockets of the shareholders, and he did not think it desirable to identify his position as a member of that assembly with that of the Chairmanship of the Company. Why they did not put in the circular calling the meeting the amount which the Government offered them was simply because he had hopes that there might be an improvement on the present offer to announce to the meeting, in which unfortunately up to that hour he had been disappointed. He concluded by repeating his belief in the urgency of accepting the resolution he proposed.

The amendment was then put to the meeting, and declared lost.

The original resolution was afterwards put and declared carried by a large majority.

A series of resolutions were afterwards passed, authorising the dissolution and voluntary winding-up of the Company, and appointing as liquidator Sir Julian Goldsmid, the Hon. Mr. Brand, and Mr. Clare (the Secretary).

A vote of thanks to the Chairman terminated the proceedings.

The Telephone Company of Ireland (Limited).

Report of Directors, to be presented at the tenth ordinary general meeting of the proprietors, to be held at the offices of the Company, Commercial-buildings, Dame-street, Dublin, on Saturday, the 6th April, at twelve o'clock.

The total number of wires (exchange and private, under rental upon 31st December, 1888, was 970. The Municipality of Cork having given permission to erect the requisite poles in the public thoroughfares, a telephone centre has been established in that city. As the exchange was only opened on January 1 last, the subscribers to the Cork centre are not included in the number of the Company's subscribers stated in the previous paragraph as being under rental on December 31, 1888. It will be satisfactory to the shareholders to be informed that the subscribers who had signed contracts before December 31, 1888, for connection with the Company's exchange, exceeded in number those to the local Post Office Exchange, notwithstanding that the latter has been open for more than three years. A large accession to the number of the Company's subscribers in Cork is confidently anticipated during the current year. A trunk line, giving communication between Cork and Queenstown, has also been erected, and will shortly be opened. Other trunk lines to the outlying districts of the city of Cork are in contemplation, some are in course of erection, and it is expected that the Cork system will shortly become one of considerable importance.

Encouraged by the success of the establishment of the exchange in Cork, the Directors are now taking the requisite steps to extend the Company's operations to Limerick. Permission for the erection of the poles in the thoroughfares has been given, and this work is now in hand. It is also proposed to extend the Company's system in other directions so soon as the necessary permission and way-leaves can be obtained.

Owing to the additional labour cast upon the Board by the extension of the Company's operations, it is proposed to fix the Directors' fees from 1st January, 1889, at £300 per annum, and the fixed salary of the managing director at £250 per annum.

The amount standing to the credit of the net revenue account, including the balance of £366. 1s. 5d. brought from last account, amounts to £4,643. 17s. 8d., against £4,314. 3s. 6d. for the year 1887. Out of this sum there has been paid an interim dividend upon the preference shares for the half-year ended June 30, 1888 (£942. 15s. 9d. paid in July last), also the interim dividend upon the ordinary shares (£875 paid in August), leaving an available balance of £2,826. 1s. 11d., as shown in the balance-sheet, since reduced by payment (on January 14) of the dividend upon the Preference shares for the second half of the year to £1,837. 5s. 9d., which the Directors propose to allocate as follows:—For the payment of a dividend on the Ordinary shares for the second half of the year at the rate of 1¼ per cent. per annum (absorbing £1,093. 15s.), equivalent to £1. 2s. 6d. per cent. for the entire year, against 1 per cent. for the year 1887, and ¾ per cent. for the year 1886, and to place to the credit of the reserve fund £417. 13s. 2d. (being 10 per cent. upon the net profits of the year), carrying forward the balance of £325. 17s. 7d. to the credit of the current year, as against £366. 1s. 5d. brought on from 1886.

In conformity with the Articles of Association, Mr. Arthur Dudgeon and Mr. Robert Worthington retire at this meeting, but are eligible for re-election. The auditor, Mr. John M. Kean, also retires at this meeting, but is eligible for re-election.

NEW COMPANIES REGISTERED.

LAING, WHARTON AND DOWN CONSTRUCTION SYNDICATE (LIMITED). This syndicate was registered on the 18th inst., with a capital of £40,000, in £100 shares, to acquire certain apparatus and articles, undertaking, and installations, belonging to the business of Messrs. Laing, Wharton and Down, of 82A, New Bond-street, in connection with the Thomson-Houston International Electric Company's system of electric arc and series lighting. The subscribers are:—P. G. B. Hechnacott, C.E., Newcastle-on-Tyne; J. T. Merz, Newcastle-on-Tyne, chemical manufacturer; Lieut.-Colonel B. H. Martindale, C.B., Bickley, Kent; J. Tennant, Gateshead, chemical manufacturer; W. Crewdson, 60, Courtfield-gardens; E. Waterhouse, 44, Gresham-street, chartered accountant; H. G. H. Norman, 5, Southwell-gardens, barrister. The vendors are appointed managers, and will be entitled to £500 per annum for office rent and salary, and also to 10 per cent. of the annual net profits, but not exceeding £2,000 in any one year.

THE BATH ELECTRIC LIGHT COMPANY (LIMITED).—Registered by Shaw and Blake, Doctors'-commons, with a capital of £25,000, in £10 shares. Object, to adopt and carry into effect an agreement dated March 8th, 1889, made between C. J. Wharton, F. J. Down and A. F. Davies, of the one part, and J. Chivers on behalf of the company of the other part, being an agreement for a license to use and work the Thomson-Houston system of electric lighting in the city of Bath, and within a radius of five miles. The first subscribers are:—Major-General J. Burn, 17, Lansdown-crescent, Bath; Major-General C. A. Benson, Ormond House, Bath; H. G. Massingham, Claremont, Oldfield-road, Bath; J. Chivers, 2, New Bond-street-buildings, Bath; A. Taylor, 8, New Bond-street, Bath; J. Ricketts, 26, Grosvenor, Bath; W. Jeffery, 2, Northumberland-building, Bath. The number of Directors shall be nine, or such smaller number, but not less than three. The first are Major-General J. Burn, Major-General C. A. Benson, J. Chivers, H. G. Massingham, and A. Taylor. Qualification, not less than 100th part of the subscribed share capital. Remuneration, £50 on every £5,000 or fractional part of £5,000 of share capital or debenture of the company, provided a 5 per cent. dividend is first earned on the paid-up share capital.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 22nd, 1889, amounted to £5,670.

THE EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The accounts of this company to the 31st December last show, subject to audit, a balance of profit of £134,851 after payment of three interim dividends. The directors propose to distribute on the 15th April proximo the usual dividend of 2s. 6d. per share, making a total dividend of 5 per cent. for the year 1888. It is also proposed to pay a bonus of 3s. per share, or 1½ per cent., making a total distribution of 6½ per cent. for the past year. The balance of £66,101 has been carried to the reserve fund, which now stands at £690,455. The share register of the company will be closed from the 6th to the 13th April, both days inclusive.

GLOBE TELEGRAPH AND TRUST COMPANY.—The directors of this company have declared an interim dividend of 3s. per share for the current quarter, payable on the 18th prox.

REUTER'S TELEGRAM COMPANY (LIMITED).—The twenty-fifth ordinary general meeting of this company will be held on April 17th, for the reception of a report and balance-sheet and the declaration of a dividend, &c.

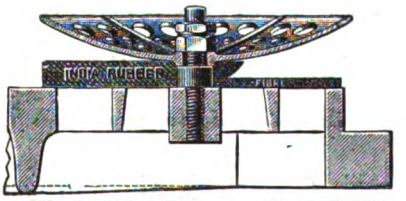
WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 22nd, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,130.

Mr. A. B. Blackburn, Assoc.Mem.Inst.C.E., has resigned the position which he has held for some years as resident engineer to the Edison and Swan Company, and has joined the staff of Messrs. Mather and Platt's electrical department, as assistant manager.

Messrs. Mather and Platt, of Salford Iron Works, Manchester, have opened a London office at No. 16, Victoria-street, Westminster, which will be under the charge of Mr. Hardman A. Earle, who has been for some years the assistant manager of their electrical department.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1888.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

JABLOCHKOFF'S

DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
Hammond & Co.
J. G. Statter & Co., Limited.

MANVILLE & MADGEN, *Managing Directors.*

3, Prince's Mansions, Victoria Street, Westminster.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 568.—Vol. XXII. FRIDAY, APRIL 5, 1889. Price Fourpence.

NOTES.

The Board of Trade Inquiry into the Metropolitan Electric Lighting scheme (which is being held at the Westminster Town Hall, and not at Richmond-terrace, as at first announced), commenced punctually at half-past ten on Wednesday morning; when it is likely to terminate is a question beyond mortal ken. No less than forty-nine Corporate bodies of one sort and another have secured a *locus standi*; and as they are every one of them entitled not only to bring witnesses of their own, but also, if they see fit, to cross-examine every witness brought by the remaining forty-eight, it is obvious that the proceedings may easily last to least as long as the Parnell Commission. We venture, however, to hope and believe that the fullest rights of cross-examination will not in every case be exercised—in that case we may get through in a few weeks or months.

The proceedings commenced with a brief statement from Major Marindin, R.E. (who is assisted on technical points by Captain Sankey, R.E.), to the effect that the form of the inquiry would approximate as closely as possible to that observed in the case of Private Bills coming before a Parliamentary Committee. The promoters of the various Provisional Orders would, therefore, be entitled to open the proceedings in each case; then the various Local Authorities and others would be heard in opposition; and, finally, the promoters would have the right of reply. It was, moreover, intimated that the Provisional Orders (of which there are thirteen under consideration) would be taken *seriatim*, an arrangement which caused visible grief to the representatives of the Vestries, who naturally wanted the Inspector to deal with each area in turn in respect of all the Orders relating to it.

Mr. Pember, Q.C., then spoke for two hours on behalf of the London Electric Supply Corporation's Order. His company wanted no monopoly. They only asked that the Board should recognise the principle that more than one company might be admitted to the same area. If, however, the Board decided otherwise he would respectfully submit that the area mentioned in his Provisional Order (comprising the entire central district of the metropolis) be granted to his clients. He hoped Major Marindin would visit the works at Deptford before the termination of the inquiry; he might say that they were "large and compact." To supply a district containing only 200,000 inhabitants with the electric light from a station in the centre of the area would necessitate a daily to and fro procession of 204 coal carts. The learned counsel then proceeded to deal *seriatim* with the leading objections which had been raised by the Vestries to various clauses of the Order. All this may be studied in detail on another page.

At the termination of Mr. Pember's address the City Remembrancer (Mr. Goldney) craved leave to state that the City of London, in virtue of its ancient privileges, and charters held itself to be exempt from the operation of the Electric Lighting Act. The question of the lighting of the City would be dealt with in its own way, and, with due respect, without reference to the Board of Trade. He should be glad, however, if the Inspector would give him a convenient opportunity to discuss the matter at greater length. Major Marindin was, however, unable to depart from the position already laid down, that each area would be dealt with in respect of each Order applying to it. The attitude of the City promises to become interesting.

The examination and cross-examination of Lord Crawford occupied the whole of Wednesday afternoon, and was not concluded until half-past two on Thursday. The ground traversed had nearly all been covered in the opening speech of counsel, so that the proceedings became slightly monotonous. The examination of Mr. Ferranti occupied the remainder of yesterday afternoon. Mr. Ferranti described the technical details of the Deptford scheme, with which, however, our readers are already familiar (see especially *Electrician*, October 26, 1888). It is interesting to learn that the experiments on high E.M.F. have now been pushed up to 1,000,000 volts; and that this difference of potential has failed to break down the insulation of the three-quarter inch of brown paper and ozokerite which separates the concentric conductors in the Ferranti main.

We would call special attention to the fact that a Paper on Underground Conduits and Electrical Conductors will be read by Mr. J. B. Verity at the meeting of the Electrical Engineers on Thursday next. In view of the great importance of the subject, we look for a useful and animated discussion. We believe that Mr. Verity will first deal with the necessity of employing some form of duct or conduit for the cables, instancing what has been done in the States, and giving diagrams of three or four of the principal conduits in use there. One of the main points he will raise is that of the necessity or otherwise of lead sheathing. The question as to what is the best form of insulation, both as regards material and the form of the conductors, will also be dealt with.

At the recent meeting of the Electrical Section of the Chamber of Commerce some informal conversation took place upon a suggestion of the Chairman as to the appointment of an official to assist in the transaction of the business of the Section. Provided only that the right man be found for the post—which need not present much difficulty—not only do we think that such a step would be beneficial, but we shall presently try to show that if the purposes of the organisation are to be at all adequately fulfilled it is imperatively necessary. We recently mentioned that the Electrical Section and its various committees have been holding meetings with not less than ten times the average frequency of the remaining Sections of the Chamber. The amount of additional labour which must have been entailed upon the able and courteous Secretary of the Chamber probably no one but himself can fully appreciate. And although not the slightest expression of any such feeling has been drawn from Mr. Murray, yet as new-comers the members of the Section can scarcely avoid a slightly uneasy feeling at having taken such full advantage of Mr. Murray's readiness to place his services ungrudgingly at their disposal. There is, however, another side of the question which, from a business point of view, is of even greater urgency. It is becoming more and more evident that the interests of the Section can only be properly looked after by some one who has a thorough technical knowledge of the industry, and who possesses the confidence of the members, so as to be able when occasion requires to act upon his own responsibility (in summoning meetings of committee and so on), and someone, moreover, who will be prepared to devote a good deal of time to the business not only in the Chamber itself but also out of doors. In fact, the duties which such an officer might be usefully called upon to perform would be largely supplementary to those at present undertaken by the Secretary, and quite distinct in character.

The need for such an appointment is well illustrated by two incidents which have recently happened, in both of which by no fault of anyone in particular—the very object with which the Section was founded has been entirely frustrated. On the 4th February a committee was appointed to take action on the question of overhead wires. The question was, and indeed is, one of considerable urgency, inasmuch as the Board of Trade were already in consultation with the Local Authorities with a view to framing regulations, and—as announced the week previously in *The Electrician*—they had, moreover, requested the Council of the Institution of Electrical Engineers to appoint a committee to advise with them upon the subject. It was felt, and rightly felt, by the Section that, while the technical aspect of the question was perfectly safe in the hands of the Electrical Engineers, yet it was most desirable that the commercial element should also be represented. It was, therefore, determined that a letter should be addressed to the Board of Trade, requesting that the views of the Section be heard before a final decision was arrived at. This was two months ago, but since that step was taken no meeting of the Special Committee has been held, and absolutely nothing has been done in the affair. Last week, however, it transpired that the Board of Trade had contented themselves with a formal acknowledgment of the letter, though their reply was never brought before the Committee. We do not desire to lay any stress whatever upon the fact of the miscarriage of this reply—a mischance which may easily be accounted for. What we do desire to emphasise is the fact that, in the absence of a responsible and duly qualified official, a matter like this, of the very first importance, may be relegated to a committee which never holds a single meeting! What is equally the business of every individual member of the Committee naturally becomes nobody's business. Doubtless the chief responsibility rests with the Chairman; but, seeing the extent of the duties demanded from him as *ex officio* Chairman of every Committee, and the multiplicity of the other personal engagements which are certain to devolve upon any man qualified for such a position, this is of itself one of the strongest arguments in favour of the proposal which we are supporting.

The other incident to which we have alluded, as illustrating the necessity for the appointment of a salaried official, is of an equally telling character. Nothing can well be more obvious than the fact that when the Board of Trade announced their intention of holding a public inquiry upon the question of electric lighting in the Metropolis, it was the immediate duty of the General Committee of the Section to consider what action should be taken. The emergency which had arisen was one of a kind which the formation of the Section was expressly designed to meet. If it had been found possible to secure united action on this occasion on any particular point or points, however limited, it is certain that a powerful influence would have been exerted upon the ultimate decision of the Board. But notwithstanding the fact that the Secretary was fully alive to the importance of the case, and exerted himself to secure a meeting of the Committee, yet since the Chairman happened to be out of town, and the Vice-Chairmen were for some reason or other equally unavailable, and there was no one else authorised to call the Committee together, nothing was done. It is true that on Thursday last a "Vigilance Committee" was appointed to look after this and other matters, but the time had gone by when any united action could be taken. The result is that each individual company is now fighting for its own hand on all points, and the local authorities will probably reap whatever advantage is to be obtained from their lack of organisation.

No less than five electric launches put in an appearance at the boat race on Saturday. Three of these belonged to the Immisch Company, who also had three of their charging stations moored off Mortlake just above the Ship. The E.P.S. Company's staff were on board the "Lady Cooper," and Mr. Stevens entertained a pleasant party (including a representative of this journal) on board Mr. Reckenzaun's launch "Volta." After the race most of the launches proceeded up the river.

The experiments described in Mr. Preece's interesting Note "On the Disturbances Arising from the Use of Earth for Electric Lighting Purposes" afford conclusive proof that the

Digitized by Google

London telephone system would be seriously perturbed if the trunk lines of the London Electric Supply Corporation were laid down in the manner at first proposed. Mr. PREECE apparently made no experiments as to the extent of the interference upon telegraph circuits; but since we understand that the POSTMASTER-GENERAL has formally vetoed the proposal, it is to be presumed that he is satisfied that the telegraph service would also have suffered. It is understood that the London Electric Supply Corporation will evade the difficulty by simply connecting the outer sheath of the concentric conductor to earth at a single point close to the machines, instead of throughout its length. The fall of potential in the 10,000-volt mains under full load between Deptford and Charing-cross will be only about 80 volts, so that the conductor may still be handled with impunity.

IT is a singular fact that with the reduced rates to the Continent, which came into operation on Monday, a reform of quite an opposite kind was silently introduced without provoking, so far as we have noticed, a single comment from the telegraphing public. Last week you could send a message to France for, say, sevenpence-halfpenny, now you cannot do so for less than tenpence, that being the minimum charge for any one message, although the rate per word has been materially lessened. That this fixing of a minimum charge has been effected without opposition speaks well for the administrative capacity of the Government departments; but it also indicates that the public are beginning to recognise the right of cable owners to guard themselves against the too economic habits of their customers. The precedent will not be lost on the great cable companies, who are at present suffering under a word-rate pure and simple, with no service-tax or minimum charge to protect them from absolute loss.

THE persons calling themselves the "British Association of Medical Electricians" recently had the effrontery to attempt to enter into "official" relations with the Institution of Electrical Engineers. We need hardly add that their overtures met with very scant consideration.

As a tribute of respect to the late Mr. PATEY, whose administrative talents were for so many years devoted to the service of the British Postal Telegraphs, we hope shortly to publish a steel-plate engraving of him in *The Electrician* portrait series of electrical notabilities issued by this journal.

Electric Lighting Tenders.—Full details will be found in our advertisement columns of the electric lighting tenders invited by the town of Brussels, and by the directors of the new Exeter Theatre.

Brazilian Submarine Telegraph Company's Debentures.—The drawing for payment of the Five per Cent. Debentures (1884 issue) is announced for the 12th inst. Particulars will be found in our advertising columns.

Worcester.—At a meeting of the Watch Committee, held on Friday last, a letter was read from the Anglo-American Brush Electric Light Corporation offering to send a scheme for lighting the city with the electric light. The letter was referred to a sub-committee.

Western Australian Cable.—The Telegraph Construction and Maintenance Company's s.s. "Seine" completed the laying of the cable from Java to Roebuck Bay, Western Australia, on 27th February, and the thirty days contractor's guarantee having expired, the cable has been taken over by the Eastern Extension, Australasia and China Telegraph Company.

Newcastle.—The Newcastle and District Electric Lighting Company have published the notice legally required of their intention to apply to the Board of Trade, under the Electric Lighting Acts, 1882 and 1888, for a license authorising them to supply electricity for public and private purposes in Newcastle.

The British Electric Light Company (Limited).—According to the scheme of arrangement approved of by the Court, each creditor of this company is entitled to receive one-half of his debt in £10 fully-paid shares bearing preferential interest of 10 per cent. The offices of the Company are at 11, Delahay-street, Westminster, S.W., and the secretary is Mr. J. M. Brett.

Electric Traction in France.—Electricity will be used on the local railway line now in course of construction between Clermont-Ferrand and Royat. The motive power will be derived from a 150 horse-power dynamo at Montferrand. The current, which will have a pressure of 500 volts, will be taken to the cars by an overhead wire, the rails being used as a return. Each train will usually consist of two cars holding fifty persons each.

Colchester.—An extensive system of electric lighting recently established in the steam flour mills of Messrs. Edward Marriage and Son, Colchester, was on Thursday formally inaugurated in the presence of the mayor (Mr. E. J. Sanders) and other gentlemen. The work was carried out by Messrs. Christy, Son and Morris, of Chelmsford. The mill is lighted by 120 16 candle-power incandescent lamps and four arc lamps. The dynamos are by Crompton and Co.

Society of Arts.—The following is the syllabus of Mr. Vernon Boys' lecture on the measurement of radiant heat, at the Society of Arts, on Monday evening next:—Thermo-piles and thermo-elements, Lord Rosse's arrangement, Hutching's instrument, Professor Forbes' instrument, The advantage of reducing the size of the bars, Details of manipulation in the case of very small bars, The construction of galvanometers to be used with thermo-piles and for some other purposes.

Post Office Telegraph Revenue.—The Revenue Returns to the end of the financial year 31st March, 1889, were published on Monday, and show the following results for the Telegraph Service:—

	Quarters Ended.				
	June 30.	Sept. 30.	Dec. 31.	March 31.	Total.
1888 9	£480,000	£565,000	£515,000	£520,000	£2,080,000
1887-8	465,000	540,000	465,000	480,000	1,950,000
Increase during 1888-9	£15,000	£25,000	£50,000	£40,000	£130,000

A Remarkable Span.—The wire belonging to the Western Counties and South Wales Telephone Company, which crosses the entrance to Dartmouth harbour, has the remarkable span of nearly half a mile, viz., 800 yards. On leaving the Dartmouth side the wire is 332 feet above high water mark, it drops to 198 feet near the Kingswear side, and then rises again to 207 feet. The wire is very fine and light, being of No. 17 silicium-bronze, weighing 24lb. to the span. This line has already withstood several strong gales in a most satisfactory manner.

Southampton.—The Special and General Works Committee of the Southampton Town Council recently reported that they had considered a letter from the Southampton Electric Light and Power Company (Limited), for permission to open the pavement in the main streets of the town for the purpose of laying underground mains. They recommended the Council to sanction the principle of electric lighting as proposed, subject to the details and other conditions being hereafter approved by the Committee and the Corporation. The report was adopted after discussion.

The Electrical Omnibus.—The electrical omnibus left the depôt of the Ward Electrical Car Company on Tuesday morning, and ran to Euston Station. Some of the directors and

Digitized by Google

the manager of the Liverpool Tramways Company were awaiting it, with Sir George Baden-Powell, M.P., and Mr. Houlding, the chairman of the sanitary committee of the Liverpool Corporation. The omnibus returned by way of Euston-road, Great Portland-street, and Regent-street, to the company's depôt at James-street, Haymarket. It came through the crowded traffic without exciting any alarm on the part of even private carriage horses.

Norwich.—At a meeting of the Norwich Town Council on Friday last, Mr. Green moved, on the recommendation of the Libraries' Committee, that the estimate of Messrs. Laurance, Paris, and Scott to place electric light wires and fittings in the ground and reading-room floors of the Free Library for the sum of £90, and to supply electric light according to the specification at the sum of £80 per annum, be accepted. "No one," said Mr. Green, "who had visited the library since the provisional introduction of the electric light would doubt the advantage." The motion was passed.

Liverpool.—The special committee of the Watch Committee of the Corporation appointed to examine the proposals of the Liverpool Electric Supply Company met last week. A number of representatives of the company attended the meeting, and after a discussion between them and the committee, extending over two hours, a mutual understanding was arrived at by which, while certain concessions are granted to the company, making them in a sense tenants of the Corporation, the interests of the ratepayers are protected. This decision has to be confirmed by the Watch Committee, and then by the City Council.

A New Method of Teaching Chemistry.—There may be more method than madness, says the *Scientific American*, in the longing of the American student for a finishing course at a German university. At a recent discourse on chemistry, Prof. Heinrich Hoffman, of Berlin, illustrated the atomic constitution of organic compounds by the use of the ballet. Each girl was dressed in an individual solid colour and represented an atom, and the grouping and movements of the atoms is said to have been very effective. Chemistry has now become a very popular study with the students, and the attendance at the lectures is very large.

Halifax.—The use of the electric light at Halifax is about to be tried under more satisfactory conditions than has been attempted hitherto. During the past week lamps have been fixed in front of several shops, chiefly by the Schmidt-Douglas Company, of Bradford, and two local firms, Messrs. Blakey, Emmott and Co., and Messrs. Luther, Hanson and Co., are also bestirring themselves. As a result of applications made to the Town Council, a special committee has been appointed to consider the matter, and have recommended the Council to give consent for the carrying of wires, &c., over the public streets. A public company is being formed for supplying electric lighting.

Messrs. Nalder Bros. and Co.'s Catalogue.—The latest catalogue of this well-known firm of instrument makers has been considerably enlarged, and its appearance is much improved by the addition of engravings. Quotations are given for a large variety of standard cells, galvanometers, resistance boxes, condensers and other laboratory apparatus. Messrs. Nalder's new ammeter and voltmeter and their cell testing voltmeter are brought to the notice of the public for the first time: the latter instrument should prove of great use to anyone in charge of secondary batteries. We recommend this neatly got up and comprehensive price list to anyone desirous of purchasing electrical testing and scientific apparatus.

Electricity and Light.—Dr. Moser (*Eder's Jahrbuch für Photographie*) draws attention to the following curious phenomena:—The leaves of an electroscope are caused to diverge by charging with, say, 150 cells. On allowing a ray of direct sunlight to fall on the instrument the divergence is increased, and it returns to its original amount when the light is cut off. A common match (sulphur with phosphorous tip) will glow in the dark when brought close to a charged body such as the cover of an electrophorus. The mercury in a capillary electrometer falls when a ray of sunshine falls on it, just as it does when connected to the zinc of a battery. The effect is distinctly electrical, not thermal, as it vanishes when the upper and lower mercury columns are short-circuited by a wire.

Ballymena.—The electric light seems to be meeting with considerable favour at Ballymena (Antrim), the following mills and private residences being lit by electricity:—Mr. J. Gault's mills and Messrs. Kane Bros.' foundry are lighted by about 100 incandescents, which are run off a dynamo installed about 150 yards away. Messrs. J. H. and G. Bellis' factory and bleach works have an installation of 400 lights. Messrs. Morton and Co.'s large flour mill is lighted entirely by electricity, the dynamo being driven by a large water-wheel; the lights in Mr. N. Morton's private house are also run off the mill dynamo. At Messrs. Raphael and Wolesley's handkerchief factory the dynamo is driven direct off a Beck gas engine. At "Leighinmohr," the residence of Mr. Thomas Anderson, the lights are run off a dynamo 250 yards distance from the house, and driven by a water-wheel. The wires from the dynamo are carried overhead to the house in a single span.

Tramway Companies and Electric Traction.—The following remarks are taken from Mr. W. W. Duncan's monthly report on Tramways and Miscellaneous Securities:—"It rests entirely with the local authorities whether the progress of electricity as a motive power will be rapid or not. In our own metropolis there must be at least 10,000 horses employed upon the various tramways, and surely the removal of those from our streets would of itself be in many ways a very great advantage. At present the companies are all somewhat coquettish in their very natural desire to reap the full benefit for their shareholders, but their eyes will soon be opened to the fact that the pioneers of electricity are not philanthropists, but shrewd business men, who will not move a step until they see clearly that they, as well as the shareholders, are to be the beneficiaries. What is wanted is frank and cordial co-operation, the tramway companies giving the facilities, and using what influence they may possess with the local authorities, and the pioneers taking the risk, which they are quite able and willing to do."

The Post Office and the Telephone.—The Chairman of the United Telephone Company has sent to *The Times* for publication the following letter, which was addressed to the Post Office four years ago:—

"Oxford-court, Cannon-street, March 11, 1885.

"DEAR SIR: The United Telephone Company, being very desirous to extend to the entire public of London the facilities afforded by their telephone exchange, beg for that purpose to make a proposal to the Post Office which they trust will be favourably considered.

"The company is ready to place one or more telephones in every Post Office within the London postal district for the use of the public, who by this means will be enabled to communicate instantly with any of the subscribers to the exchange, now numbering not far from 4,000 of the most important business firms and private persons in London, and daily increasing. My company would be willing to make special terms with the Post Office for such a service, and to make any reasonable arrangement that the Department desires, including the right to the Post Office to take the entire revenue from the fees payable by the public for the use of the telephone.

"Probably, as the Post Office is about to introduce the system of sixpenny telegrams, the same charge of sixpence might—at least in the beginning—be fixed for a telephone talk of a certain number of minutes.

"My company is, however, quite willing that the Post Office should fix the rate, provided it be not too high, the object of my company being, as I have said, to afford to the entire public of the metropolis the utmost possible facilities for the use of the telephone.

"Hoping for an early and favourable reply,

"I am, dear Sir, yours faithfully,

"THOS. BLACKIE, Secretary.

"C. H. B. Patey, Esq., General Post Office, E.C."

Duties on Electrical Apparatus Imported into France.—The following circular has been issued by the Information Department of the London Chamber of Commerce:—"The Board of Trade have kindly communicated the following Memorandum, based on the latest information in the possession of the department, for circulation to the members of the Electrical and Allied Trade Sections, showing the duties levied by France on (1) dynamo-electric machines—(*a*) If weighing less than

Digitized by Google

30 kilos. these are admitted free of duty, on the same footing as 'scientific instruments;' (*b*) if weighing 30 kilos. or more they are charged with duty as 'machinery unenumerated,' the duties upon which category are:—Containing 75 per cent. or more of cast iron, per 100 kilos, 6fr.; containing from 50 to 75 per cent., 10fr.; containing less than 50 per cent., 15fr. (2) Electric lamps—Accessories of electric lighting, such as commutators, regulators, lamps, &c., are chargeable as manufactures of metal, according to class, the duty upon such as are of copper or of copper mixed with zinc or tin being at the rate of 20fr. per 100 kilos. Incandescent lamps of blown glass are chargeable as 'Articles of glass not otherwise mentioned;' the import duty under this head 18fr. 50c. per 100 kilos. Accumulators are charged according to the metal of which composed."

The Elieson Sale.—The sale of the plant and patents of the Elieson Electric Company, which takes place within the next fortnight, will not, we venture to think, finally discourage the advocates of battery traction in this country; at any rate, the Elieson system, although it has unfortunately not succeeded in obtaining a permanent foothold on the North Metropolitan Company's line, will, nevertheless, always occupy an important place in the history of electric traction in the United Kingdom. During the nine months that the service on the Manor Park line was well-nigh continuously running, over 400,000 passengers were carried and about 41,000 car-miles were run, and although the system has not been an entire success, it is very far from a failure, an improvement in the batteries being the chief desideratum. The points upon which the proprietors chiefly rely are: the safety arising from the low tension used (180 volts); the adaptability to existing lines; the low cost of first installation, since no alteration of cars or track is required; durability and reliability. The Elieson system, which was described in *The Electrician* (October 21, 1887), involves, as will be remembered, a separate engine car; the motor itself revolves, carrying with it a bevel wheel, which drives at will a right or left-hand bevel wheel on the car axle. We gather from the handsome catalogue issued by Messrs. Wheatley, Kirk, Price and Goulty, that the sale will include the patent rights in Great Britain and Ireland, the United States, Austro-Hungary, Belgium, France, Germany, Italy, Portugal, India, Canada, the Cape, New South Wales, and Queensland, the purchasers of the English patents also obtaining the generating station, plant, and running privileges on the North Metropolitan Tramway Company's lines. The catalogue, we may add, contains some remarkably good illustrations of the Elieson Company's works.

Ship Lighting.—Messrs. W. H. Allen and Co., of York-street Works, Lambeth, have just completed the lighting of a large passenger vessel, built by Messrs. Laird Brothers, Birkenhead, for the Compania Sud Americana de Vapores. The vessel, named the "Imperial," is one of 2,000 tons burthen, propelled by engines of 4,000 horse-power, and is specially built for the trade between Valparaiso and Callao. The boat is fitted with the most modern appliances, and the saloon is lined with maple and satin wood beautifully ornamented with carvings and luxuriously upholstered. The electric light has been provided for every part of the ship, from the mast head to the coal bunkers, and employs over 230 glow lamps of the Edison-Swan type. The signal lights are considerably stronger than can be provided by the best oil lamps, and are so fitted that oil can be substituted, if needful, at a moment's notice. Special brackets are supplied for loading purposes. In the engine room, bunkers, and holds, plugs have been inserted so that the current may be tapped, and a powerful light concentrated in any given spot for temporary purposes. The electroliers for the saloon have been designed to suit the fittings and furniture, and are adapted both for oil and electricity. The lamps exposed to rough usage are enclosed by damp proof bell glasses, and these are protected by strong wire cages. Cockburn's slate switches and fuse boxes have been plentifully used throughout, each state room being separately connected. The conductors branch into six circuits from a six-way slate switch-board, and a second board with the main fuses and fitted with a voltmeter is placed on the return circuit. All the wires are enclosed in wood casings. The "Kapp" dynamo is compound-wound, and capable of feeding the whole of the lamps at the low speed of 280 revolutions per minute. It is driven direct by an Allen twin engine at a steam pressure of 160 pounds. The engine and dynamo are so fitted as to work without vibration, and no sparks are visible at the brushes. The installation has been superintended throughout by Messrs. Allen's electrician, Mr. J. W. Kempster, and gave universal satisfaction on the trial.

The Post Office and the Continental Cables.—A Parliamentary paper bearing the signature of Mr. Raikes, Postmaster-General, issued last Friday, contained the following memorandum explanatory of the relations entered into with Germany, Holland, Belgium, and France as regards the working of the submarine telegraph cables to those countries:—

On the transfer of the telegraphs to the State in 1870, the Post Office became possessed of the cable known as "Reuter's cable" between England and Germany, and two cables between England and Holland previously the property of the Electric and International Telegraph Company. The cables between England and Belgium, and between England and France, remained the property of the Submarine Telegraph Company.

Under an agreement scheduled to the Telegraph Act, 1868, it was arranged that the whole of the cables should be worked and maintained by the Submarine Telegraph Company, and that the land lines in connection with the cables should be maintained by the Post Office. The agreement provided that the earnings from the cables, after certain deductions for maintenance and working, should be divided between the Post Office and the company in the proportions set forth. The arrangements thus entered into were to last until the expiration of the concessions granted by France and Belgium, under which the company had obtained a monopoly of the telegraph business between Great Britain and those two countries. The concessions expired in January, 1889, but as a matter of mutual convenience the arrangements with the company have been extended to the 31st inst.

In 1884 it became necessary entirely to renew one of the cables to Holland, and partially to renew the other. This was work not coming within the definition of maintenance, and under the agreement it had to be undertaken by the Post Office. An expenditure of £45,000 was authorised for the purpose by the Government of the day.

Since 1872 Great Britain has been a party to the International Telegraph Convention, which regulates the international relations between States which possess internal telegraph systems. In the case of all the Continental European States there is a direct interchange of telegraphic correspondence between neighbouring States, and the desire naturally arose that there should be direct transmission of telegrams between England and her nearest neighbours without the intermediary of a private company. Representations to the same effect were received by the Post Office from Chambers of Commerce and other bodies in the United Kingdom. It was obvious that the cessation of the monopoly of the private company might be expected to yield results beneficial not only to the revenue of the countries concerned, but also to the interests of the public. An intermediate stage of transmission would be dispensed with, the rapidity of communication would be improved, and an appreciable reduction in the tariff made possible. Accordingly negotiations were entered into with the German, Dutch, Belgian, and French Governments, and agreements, which will be presented in due course, have been concluded.

With the French and Belgian Governments conventions have been concluded for the purchase, at the joint expense of the respective countries, of the cables of the Submarine Telegraph Company. In the case of Holland a half-share in the two cables connecting that country with Great Britain, which at present belong to the Post Office, will be purchased by the Netherlands Government. In the case of Germany a cable laid between Germany and England by the German Union Telegraph Company has been purchased by the German Government, and the cable between Lowestoft and Norderney, formerly known as "Reuter's cable," will remain the property of this country. A joint interest will thus be created in the cables, and they will be maintained at the joint expense. Each country will provide, maintain, and work its own land lines in connection with the cables, and any additional cables required to meet the increase of traffic are to be laid at the joint expense of the countries concerned. The charges for telegrams, which are at present 3d. per word to Germany and Holland, 2½d. to France, and 2d. to Belgium, will be fixed uniformly at 2d. per word, with a *minimum* of 10d. for a message. Direct wires will be established between Liverpool and Hamburg and between Liverpool and Havre, and various arrangements are being concerted with the Continental telegraph administrations with the object of improving the working of the wires and increasing the speed of transmission of messages.

THE PHONOPORE.

We now proceed, in accordance with the promise in our last issue, to describe in some detail the system of telegraphy devised by Mr. Langdon-Davies, and which is based upon the employment of the special apparatus which he calls the "Phonopore:"—

The phonopore consists essentially of an induction coil, having one primary and two secondary wires. In circuit with the primary is the battery, transmitting apparatus (Morse key or otherwise), and a vibrating reed. One of the two secondary coils has one end put to earth, while the other is insulated. The other secondary coil has its opposite end insulated, the wire then going to line. The apparatus is, therefore, equivalent to a condenser with self-induction; there is, moreover, no conductive circuit at all between the transmitting instrument at the home end and the receiving instrument at the distant end of the line. The manner in which the phonopore can be made to work side by side with the ordinary telegraphs without in any way interfering with them, or being interfered with by them, will now be shown by describing in detail the actual phonopore line between St. Pancras and Leicester, and two or three of the numerous arrangements of phonoporic apparatus which Mr. Langdon-Davis has carried out in his laboratory. The line upon which the recent demonstration was made is an ordinary telegraph line, 130 miles long, connecting London and Derby (Fig. 1). At the London end of the wire there are two telegraph stations, T_1 T_2, about half a mile apart, and at Derby there is a third telegraph station, T_3, all working ordinary

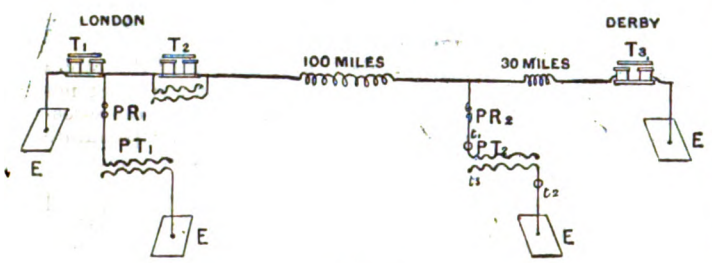

FIG. 1.

T_1 T_2 T_3 = Morse Instruments. P R_1, P R_2 = Phonopore Receivers.
P T_1, P T_2 = Phonopore Transmitters.

Morse instruments through ordinary relays in the ordinary way. At the London end of the line the phonopore is installed in deviation on the line ten yards from the terminal station T_1, the distant phonopore being also in deviation at a point about 30 miles from T_3. One end of the phonopore line is therefore in close proximity to two ordinary telegraph stations less than a mile apart, while the distant post is on a branch line taken from a point in the main line where there is no other instrument. Under these conditions the phonopore works absolutely independently of the ordinary service. In Fig. 2 we see the details of the phonopore station. The transmitting circuit, P T, consists of a Morse key, a battery of 30 cells, a vibrating reed, and the primary wire of the induction coil. The reed is set in vibration on the depression of the key by an electro-magnet (also included in the circuit), and effects a rapid succession of makes and breaks in the primary circuit. In this way the manipulation of the key sends to line through the secondary coil a succession of rapidly alternating current waves in unison with the vibration of the reed. One wire of the secondary goes to earth and the other is connected through the "transformer" to line. This transformer will presently be described in detail. A key is arranged to cut out the transformer when transmitting messages; if, however, the instrument is required to work duplex, the transformer line coils are wound differentially, and this cut-out is not used. So much for the transmitting apparatus. In Fig. 3 we have a more detailed representation of the receiving apparatus, called by Mr. Davies the "transformer," which is in reality a delicate relay designed to enable the "phonoporic" current waves to work an ordinary Morse printer, or sounder. Upon the soft iron core I are wound two coils, L C and A C; the coil L C is placed in the line wire of the secondary coils; the coil A C, called the "augmenter," is in a local circuit in which there is a permanent current from a battery. This local circuit includes, in addition to the battery and augmenter coil, a relay, a galvanometer, and the two vibrators, P V and T V, called respectively the "pendulum" and the "tongue." Over the iron core is placed a steel reed or diaphragm, R R, which, in harmonic telegraphy, is tuned to the rate of the distant transmitter intended to work it. When the transformer is at rest the

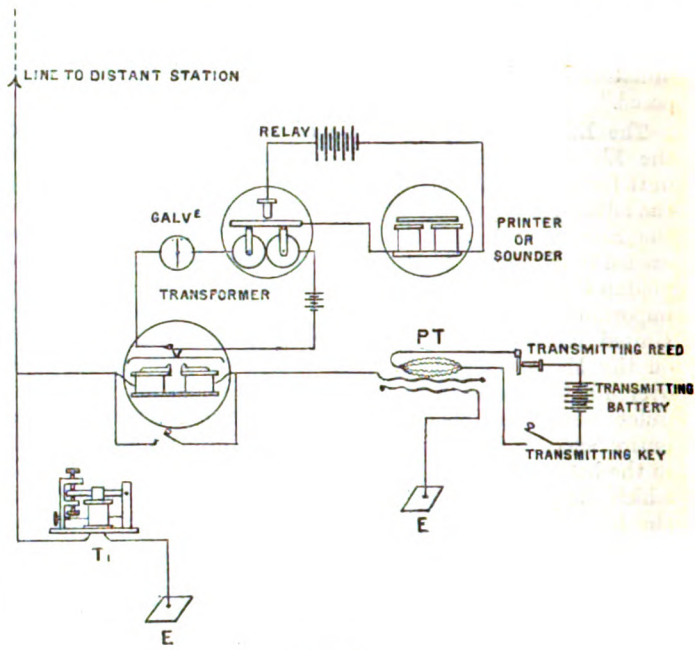

FIG. 2.

vibrator contacts are closed, and the current from the battery magnetises the core and holds the reed in a state of tension. In this condition it is important to notice that the reed is not touching the tongue. The action of the apparatus will now be easily understood. When intermittent currents reach L C from line, they act upon the reed R R. If, however, these vibrations consist of the comparatively slow and irregular impulses usual to ordinary telegraph work, or even of impulses of a regular and rapid character, but not accordant with the pitch of the reed, the vibrations of R R never acquire such an amplitude

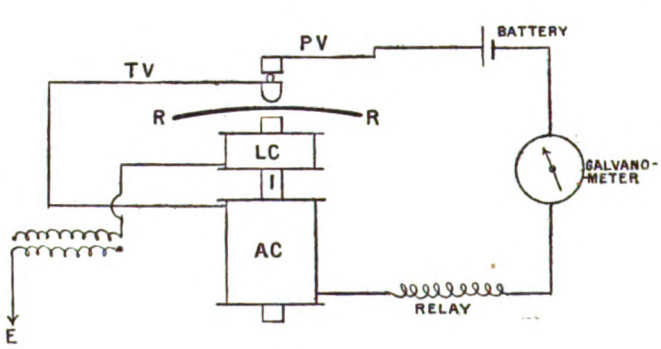

FIG. 3.

as to permit it to touch the tongue, and the contact between P V and T V is not, therefore, disturbed. On the other hand, when impulses are given to R R at a rate corresponding to its natural time of vibration, it speedily acquires such an amplitude as to cause it to touch the tongue and disturb the contact of the vibrators. This disturbance, increasing the resistance of the local circuit, reduces the strength of the current in the augmenter coil A C, and the effect is then to release the reed R R from its condition of tension, and to cause it to strike smartly the tongue T V, knocking away the pendulum D V, and so long as the impulses continue to arrive in L C, the pen-

Digitized by Google

dulum is unable to make an efficient contact with the tongue. Now the current which magnetises the core I also holds up the armature of the local relay, so that when the pendulum fails to make good contact with the tongue the armature of the relay falls and the printer, sounder, or other telegraph instrument in the relay circuit, is operated. In some cases the relay may be dispensed with altogether, and the signalling instrument is then put in circuit with the augmenter coil in the position occupied by the relay. The resistance of the London and Leicester line is, we may add, about 4,000 ohms.

Returning for a moment to Fig. 1, we would call attention to a somewhat curious result obtained by Dr. Hopkinson and Prof. Silvanus Thompson. Treating P T_2 as a condenser, Dr. Hopkinson measured its capacity between t_1 and t_2, and made it 0·5 microfarad, the iron core of the coil being in. Measuring its capacity between t_1 and t_3 without the iron core, Prof. Silvanus Thompson arrived at the value 0·083 microfarad.

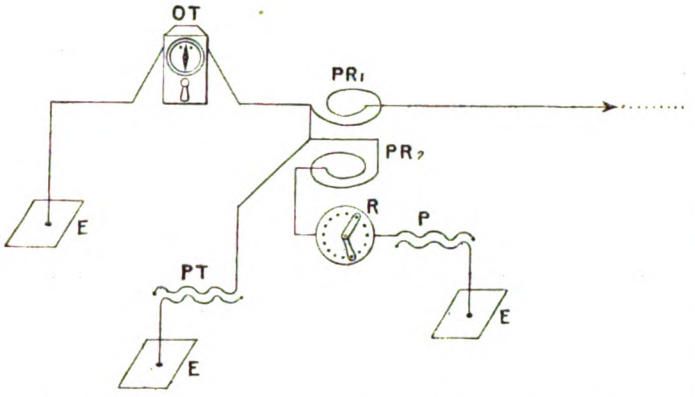

Fig. 4.—Duplex Phonopore Telegraph with Ordinary Needle Telegraph.

O T, ordinary telegraph ; P R_1 P R_2, differential coils of the phonopore receiver ; P T, phonopore transmitter ; R, Rheostat ; P, simple phonopore.

The extreme brevity of the duration of a "phonoporic impulse" suggested a doubt whether duplex receivers could be constructed so as to be practically useful. Experiment has, however, proved that there is no difficulty in working duplex receivers with ordinary differential coils, as shown in Fig. 4.

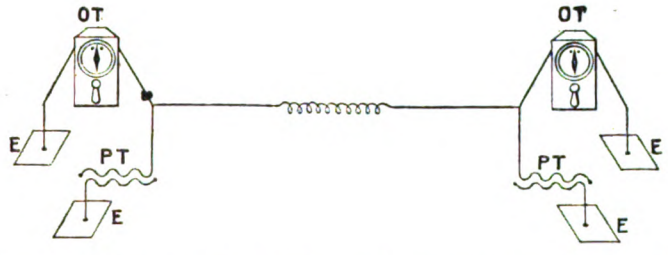

Fig. 5.—Diplex and Duplex Service, consisting of a Simplex Ordinary Telegraph and a Simplex Phonopore Telegraph.

At the recent demonstration, although it was not necessary to do so, one of the strands, P R_1, of the differential coil was placed in the line itself, the other, P R_2, in a balance line to earth, but not direct, a phonopore, P, being interposed between the rheostat and earth. It is one of the many problems suggested by this apparatus that, inasmuch as the resistance of P is infinite, there should be no necessity to add any further resistance in R. The fact, however, remains that unless this resistance is so interposed a balance cannot be obtained. But, at the same time, this system of duplexing with the phonopore has an advantage over the ordinary system, since an exact balance is not required. At the demonstration at which we were present the resistance of the line was altered from 4,000 ohms to 14,000 ohms without disturbing the balance. The balance, however, broke down when the resistance was raised to 23,000 ohms. At the same time, although the ordinary telegraph needle instruments could not be worked with their batteries of 20 cells each, the phonopores, with their batteries of 15 cells each, worked precisely as before. Another system of duplexing a line is indicated in Fig. 5, where we have an ordinary telegraph line and instruments. If, now, a pair of simplex phonopores is installed upon it, two services can at once be worked upon the single wire. The services being absolutely independent of each other, the line might, therefore, be worked either duplex or diplex, as required. In Fig. 6 yet another method of duplexing is shown. In this case there is no balance line at all to regulate, but the duplexing of the instrument depends upon the tuning of the transmitting reeds in the transmitters, and the vibrators in the receivers. P T_1 at A is a transmitter having a transmitting reed whose rate is the same as that of the receiver P R_2 at B. P T_2 at B is a transmitter, the rate of whose transmitting reed is the same as the rate of the receiver P R_1 at A. The rates of these transmitting reeds are so calculated that they not only agree with those of their respective receivers, but so that they do not interfere with their home receiver. Thus, when the transmitter at A is worked, although its impulses pass directly through the receiver at A,

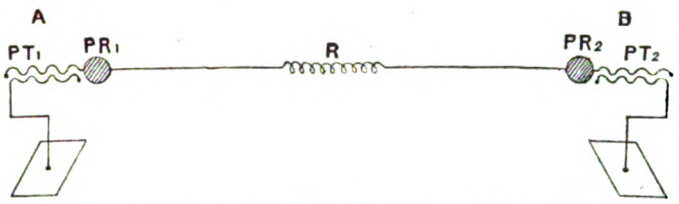

Fig. 6.—Phonoporic Line, for Harmonic Duplex Working.

they do not affect it, but they work the receiver at B, and *vice versâ*. The line shown in Fig. 6 is an ordinary "phonopore" line, terminating at both ends "in air." No ordinary telegraph can, therefore, be worked upon it. The battery power employed consists of 15 cells at each end, and the resistance of the wire is 100,000 ohms. In Fig. 7 we have a perspective view of a simplex phonopore sounder. The transmitting and receiving organs

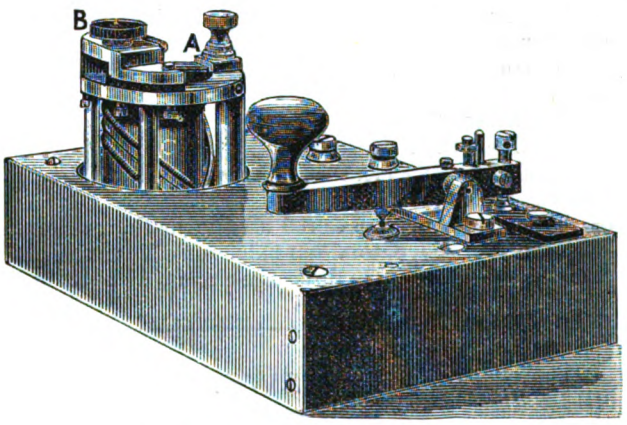

Fig. 7.—Simplex Phonopore Sounder

A = reed ; B = contact screw ; C = ends of secondary coils.

are comprised in a single instrument, and they are intended to work simultaneously with ordinary telegraphs on lines up to 200 miles long. On a simple "phonoporic" line the sounder will work to a much greater distance, the full extent of which has not yet been ascertained. It has worked well through a test line of 100,000 ohms.

We have described above only some half-a-dozen out of nearly 40 combinations and adaptations of which the phonopore is at present capable, but we think we have said enough to make plain the general principle and the chief details of this beautiful instrument. In conclusion we may mention that Mr. Langdon-Davies is at present constructing two Wheatstone automatic instruments adapted to the phonopore. These apparatus were not commenced until experiments had been made with two ordinary Wheatstone automatic instruments transmitting in place of the key of the phonopore transmitter. Although driven at the highest possible speed the phonopore showed itself perfectly competent to deal with the signals.

SUPPLEMENT TO NOTE ON BURSTING JARS.

BY DR. OLIVER LODGE.

By some mischance the note on page 586 last week was published without some alterations and additions which I had intended and sent in—perhaps too late. It will now be most convenient to annex these as a supplementary note. The only misprint I need correct is where Dr. Ingenhousz is misprinted "Ingerhouse."

When the discharge circuit is a long and thick one, say a No. 0 or even a No. 12 copper wire round a large room, a discharge spark-length of three-quarters of an inch will make a gallon jar spark over its edge a distance of six inches. It is possible that this ease of overflow may prevent it from bursting, one acting as a safety-valve to the other.

I expect jars usually burst when used singly or joined in parallel, seldom when joined in series. The double thickness of glass in the latter case is an obvious consideration, but there is more in it than that. The main reason of the greater safety of jars in series seems to me to be that the electric surgings do not operate on both coatings simultaneously to the same extent as they do with a single jar.

The suggestion at the end of Mr. Boys' letter, about the period of longitudinal vibration of the glass possibly synchronising with the electric oscillation when fracture occurs, is a good one, and future observations should be so recorded that the truth of the hypothesis can be examined. As a convenience I have, therefore, drawn up the following list of things which it is well to record whenever a jar breaks electrically. They are all such as can be easily obtained after the accident.

Data desirable to know in future observations of Broken Jars.

(1) Mode in which jars are connected if more than one.
(2) Total area of effectively coated surface.
(3) Average thickness of effectively coated glass (say by weight).
(4) Quality of the glass (viz., its specific inductive capacity roughly, or at least its specific gravity).
[Or, instead of 2, 3, 4, total capacity of jars, as arranged, before fracture].
(5) Thickness of glass near fracture.
(6) Total length of discharge-circuit.
(7) General arrangement of discharge-circuit (*e.g.*, rough scale plan of same).
(8) Thicknesses of wire or rod used in discharge-circuit.
[Or, instead of 6, 7, 8, total self-induction of discharge-circuit].
(9) Length of air gap in discharge-circuit, with size of knobs used.

REVIEWS.

Treatise on Submarine Telegraphy. By M. E. WÜNSCHENDORFF, Director of Military Telegraphy, France. (Paris: Baudry and Co. 1888.)

(SECOND NOTICE.)

Chapter 9 is occupied with the different methods of laying shore ends, and the theoretical investigations of Messrs. Longridge and Brooks, Werner Siemens and others, on the angles and curves which a cable forms in being laid, as well as the retarding stresses necessary to lay the same in different depths with a certain percentage of slack. No notice is, however, taken of the late Mr. Hockin's formula and tables.

Table II., given at page 272, shows the retarding force according to the formulæ given for different speeds of the ship (1 to 10 knots per hour), for depths from 500 to 3,000 fathoms (not *de* 500 *en* 500 brasses as printed in the text), on the assumption that the slack is 10 per cent. and the weight of the cable a constant. To be of practical use this table requires to be considerably amplified so as to take in different percentages of slack and different weights of cables. A practical example giving the actual dynamometer stresses carried in the laying of a certain cable, with all the data observed, would have been of considerable value. It is of the greatest importance when laying a cable to be able to so regulate the retarding force that the desired percentage of slack is obtained. The usual method employed is that of tightening the brakes until the speed of the cable being paid out is exactly equal to that of the ship, and then easing them until the required percentage is attained. This old method is attributed to Sir Wm. Siemens by M. Wünschendorff. We were not aware that he devised this test. He says that Werner Siemens' plan of paying out a fine pianoforte wire at the same time as the cable has been abandoned, but we believe that Messrs. Siemens still employ this method with success, although we are not aware that any of the other cable companies have yet tried it. For depths up to 1,000 fathoms the slack should be such that the cable can be lifted on the bight for repair without breaking. For greater depths it is hardly worth while to anticipate this special object, if enough slack is just given to let the cable fit the sinuosities of the bottom.

In Chapter 10 M. Wünschendorff gives a very complete and interesting account of the various causes of damage to cables that have been met with. Here we observe that he mentions the Muntz metal ribbon, successfully employed by the Eastern Telegraph Company to protect the gutta-percha core of their cables from the ravages of the teredo, but he has omitted to describe how it is bedded, applied and covered. Lightning protectors receive considerable attention, six different kinds being described. One of the most widely used and successful forms is, however, conspicuous by its absence, viz., that devised by Mr. Saunders, the electrician-in-chief to the Eastern Telegraph Company. The interesting operations of undermining and of grappling for and lifting the cable are next illustrated and described in a manner that makes them perfectly understandable to any one who has never witnessed such work.

Chapter 11 is entirely taken up with descriptions of the most important measuring instruments, and here M. Wünschendorff shows himself thoroughly at home. In his explanation of Sir William Thomson's marine galvanometer, he, however, omits to state that the mirror must be perfectly balanced, otherwise the spot of light will be continually on the move when the instrument is on board ship. We have never met with a description in any text book of how the delicate operation of effecting this necessary balancing is carried out. It is well known, however, that not one mechanician or electrician out of ten can do it so thoroughly that no movement of the mirror is perceptible when the ship is tossing up and down and swinging heavily to and fro. Before proceeding on a cable expedition, all the marine galvanometers should be tried upon an extemporised cradle along with their lamps and scales, and adjusted until no deflection of the spot is observable with a swing or a lift of 25° of the cradle. At pages 322 and 323 no mention is made of the fact that the shunt box resistance coils should be made of wire having the same specific resistance and coefficient for temperature as its galvanometer, and that they should be adjusted so as to read correctly at the same temperature. The scientific reader is, however, admonished not to "fluke" his galvanometer by leaving out the short-circuit plug of the shunt-box when applying or taking off the current! At page 331 it is stated that resistance coils are sometimes made of platinum; surely platinoid is here meant. Platinum-silver is now almost universally used for resistance coils in connection with cable work, German silver and other alloys having been given up long ago. Fig. 285, Thomson and Varley's slides, is copied from "Kemp's Handbook of Electrical Testing," and so are several other cuts from this well-known book, as well as other sources, without acknowledgment or reference note. If the connections were as shown by this figure the battery would be liable to be "run down" or nearly short-circuited when measuring very low resistances. The better plan of connecting up these slides for cable work is shown by the figures at pages 102 and 104 in "Munro and Jamieson's Pocket Book of Electrical Rules and Tables," or as indicated by M. Wünschendorff in Fig. 323, p. 366, where there is a mistake, viz., the reading should be 9,532 on the slides (*"comme l'indique la Fig. 285"*) instead of 9,568 The discrepancy between the two figures 285 and 323 is bound to be very puzzling to anyone not thoroughly acquainted with these slides.

Digitized by Google

At pages 336 and 337 we are told to keep condensers short-circuited when not in use. Excellent advice! Not a word, however, about the different rates of electrification of cables and condensers. Neither at pages 337 to 341, nor at p. 389, where Sir Wm. Thomson's method of taking the capacity of long submarine cables is detailed, is there any mention of Lambert's key, without which the connections are very awkward to join up, and the test not easy to make. Gott's method, described at page 387, is much easier to connect up, and no doubt simpler. Some electricians say that it gives equally good results.

All the methods given in Chapter 12 for taking the internal resistance of batteries are old, and are open to objections. They are not to be compared to Munro's method or to the plan of employing a voltmeter to take the difference of potential, *first*, when the battery is in open circuit, and second, when working through a known resistance with an ampere meter in circuit. Neither of these two methods is mentioned. Although almost all the ordinary tests applicable to instruments and cables are given separately, yet we do not find any general or particular information regarding the usual routine of factory testing. No mention is made of the great use of the slide rule or of calculating machines, without which factory tests and calculations would be a very laborious operation. M. Wünschendorff is evidently more at home in the tests as applied during and after the immersion of cables. He gives a full page illustration of the whole of the connections as used on board the s.s. "Dacia" during the laying of the Marseilles-Algiers cable in 1879, as well as the old ship and shore connections, devised and fitted by Willoughby Smith during the laying of the 1866-87 Atlantic cables.

In Chapter 14 all the more important as well as the latest methods of ascertaining the positions of faults in cables have received considerable attention. They have, however, been translated direct from the Papers or writings of each of the respective authors, little or no attempt being made to systematise the index or symbol letters. We do observe, however, a praiseworthy effort in some parts of the book to effect this desirable object, and that M. Wünschendorff has to a considerable extent adopted the first letter of the most important word to indicate the part referred to in a figure or electrical quantity. We see that he invariably uses ω for ohms, and Ω for meghoms, as we do in this country; but he naturally substitutes T for terre where we use E for earth, and P for pile where we use B for battery. The whole of this long chapter, extending from page 403 to page 459, has been culled and extracted, directly or indirectly, from British text-books and journals. Foreign electricians do not seem to have devised any very notable tests for localising faults in cables, if we except the well-known old Blavier test. Although British manufacturers and cable engineers have been very reticent in regard to their part of the work, British electricians have always come well to the front with their methods and devices for testing cables and telegraph lines generally.

Chapter 15 gives an elaborate and very complete investigation of the theory of the transmission of signals in submarine cables, with numerous graphic representations of the retardations of the flow due to electrostatic capacity, &c.

At page 470 the author wisely refrains from saying to whom the credit is due of first introducing condensers between the cable ends and the signalling apparatus. The patent was taken out by Cromwell Varley; but Willoughby Smith claimed the suggestion, as may be remembered from the rather warm discussion some years ago at the Society of Telegraph-Engineers. The fact that the shunting of signalling condensers by high resistances accelerates the rate of signalling is not mentioned, so far as we have been able to observe. No mention is made of Thomson and Jenkin's curb sender, or Count Siccardi's key, with which he laboured so long and tried so many experiments in order to increase the speed of signalling through long cables. In Chapter 16, after describing and illustrating the various forms of apparatus which are in use with short cables, we find complete descriptions of Sir William Thomson's mirror and siphon recorder of the latest electro-magnet pattern, with round mouse mill, &c., but a meagre illustration and description of the new permanent magnet form. He justly gives credit to the well-known Mr. De Sauty for being the first person to successfully duplex a cable—viz., that between Gibraltar and Lisbon of 365 knots in 1873. He was assisted by Messrs. Grigor Taylor and H. W. Sullivan; and the latter still possesses siphon recorder slips showing how perfectly the balance was then obtained and maintained. M. Wünschendorff is, however, evidently ignorant of the great amount of perseverance and ingenuity displayed by Mr. Benjamin Smith in successfully duplexing long cables made up of different conductor sections, or resistances and capacities, a feat which had baffled all other experimenters to overcome. His success in devising and perfecting manual translation is also omitted. Messrs. Muirhead and Taylor's system of artificial line is described, and Dr. Muirhead's experiments and tests in duplexing the Marseilles-Malta, Aden-Bombay, and Direct United States cables are given very fully, as well as the methods of Sir James Anderson and Mr. Harwood, Mr. Stearns and M. D'Ailhaud. Although there are omissions and mistakes to be found here and there throughout this most exhaustive and well-illustrated treatise, yet the perusal of its contents cannot but be interesting and instructive to all those more immediately engaged in connection with the various processes of manufacture, laying, working, and maintenance of submarine telegraphy. The laborious reading and research which the author has exhibited in its compilation, must command the respect of every one who takes the slightest interest in this subject, which, by its far reaching effects, has practically revolutionised the commercial dealings and political intercourse of nations.

a. γ.

The Theory and Practice of Absolute Measurements in Electricity and Magnetism. Vol. I. By A. Gray, M.A., F.R.S.E. (Macmillan and Co., 1888.)

This work is an expansion of the well-known and useful little handbook on "Absolute Electrical Measurements," published in 1884, but the present volume contains more than double the amount of matter in the original work. If the second volume fulfils the promise of the first the work will form a most comprehensive treatise on electrical and magnetic measurement. Chapter 1, comprising the first 135 pages, forms a very good introduction to the mathematical theory of electrostatics. It consists almost entirely of a reproduction with some amplification of the easier parts of the electrostatic portion of Maxwell's treatise: it contains sufficient to enable the student to understand the theory of the construction and use of the electrostatic measuring instruments described in subsequent chapters without referring to Maxwell's treatise. The second chapter contains the elements of the theory of the flow of electricity, with applications to the transmission of signals through submarine cables. The third chapter is devoted to the consideration of electrical units, and their expression in terms of the so-called fundamental units.

The treatment of methods of measurement is begun in Chapter 4, which contains an admirable account of the methods for the accurate measurement of angular deflections and for the observation of oscillations, with the methods of reducing the observations, together with a discussion of torsional phenomena and of the various kinds of suspension used in physical apparatus.

Chapter 5, on Electrometers, consists, as was to be expected, of a description of Sir William Thomson's instruments. We should have liked to find the theory of the guard ring gone into, either in this chapter or in the chapter on electrostatic theory. Maxwell's treatment of this offers great difficulty to the average student; indeed it forms, perhaps, the greatest difficulty of his first volume. This, however, is due in great part to the brevity of Maxwell's exposition, and a little further explanation of the different steps by which the final formula is arrived at would make it much less difficult to follow.

Chapter 6, on the comparison of resistances, is a very valuable one, and contains a good deal of matter, especially with respect to the resistance of electrolytes, which is not easily available except to students who can read German, and who have access either to the original memoirs or to Wiedemann's great treatise. Useful details are given on the care and testing of resistance boxes, and on precautions to be adopted in comparing resistances by the Wheatstone-bridge method. Several methods are given for the calibration of the wire bridge with sliding contacts,

Digitized by Google

including the admirable one described by Prof. G. C. Foster in a Paper communicated to the Society of Telegraph Engineers, and afterwards reproduced in German in *Wiedemann's Annalen*. We may take this opportunity of pointing out that this form of bridge should never be used for measurements where accuracy is required without frequent recalibration, as the wire may very easily be injured to such an extent as to give results that are not even approximately correct, without it being possible to detect the injury except by testing electrically.

The seventh and concluding chapter treats of the comparison of the capacities of condensers, and of the measurement of specific inductive capacity. The latter section contains a very good summary of recent work on the subject.

An appendix to this volume contains some tables expressing the relations between cross-section, resistance and weight of hard-drawn pure copper wire, according to the Birmingham wire gauge and the new standard wire gauge respectively.

Numerical formulæ are also given for determining the change in conductivity with temperature of the more important pure metals, and tables of the conductivity and resistance of pure copper at temperatures from 0° to 40°C., and of the specific resistance at 0° in legal ohms of various pure metals and alloys.

We can heartily recommend the volume throughout to the electrical student with a fairly good mathematical equipment, and the practical details of methods of measurement will be of value even to those who are unable to follow the whole of the theory.

Practical, Plane and Solid Geometry. Fifteenth Edition. By John S. Rawle. (London: Simpkin, Marshall and Co.)

The fifteenth edition of this useful little work has been considerably enlarged, and it now contains over 400 problems, covering the whole field of elementary practical geometry. The problems are in most cases accompanied by short notes, pointing out possible variations and extensions of the questions. Several pages are devoted to scales and scale drawing: the number of exercises on this important but often neglected subject might, however, be increased with advantage. The study of this manual should prove a useful preliminary to a course of mechanical or architectural drawing.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"On the Disturbances Arising from the Use of 'Earth' for Electric Lighting Purposes."*

BY W. H. PREECE, F.R.S., VICE-PRESIDENT.

The magnetic field produced by a current flowing in a straight wire, and returning through the earth, extends to such distances that it is quite impossible to say where or when or how a telephone circuit in that field would be disturbed by any changes in that current. It is quite certain that if a single conductor between Deptford and London were subject to rapid alternations under a potential difference of 10,000 volts—the current returning by way of the earth—every telephone circuit in the metropolis would be disturbed, and probably rendered unworkable. The law determining the distance to which this influence extends was given by me in a Paper read before the British Association at Manchester in 1887. It is given in the following equation :—

$$C_2 = \frac{C_1 l}{d^2 r_2} \times M ;$$

C_1 being the primary currents, C_2 the secondary current, l the length of the primary, d the distance between the wires, r_2 the resistance of the secondary, M a constant dependent on the frequency of the primary currents and the rate at which they rise and fall.

It follows from this formula that currents of rapid frequency on a conductor 10 miles in length, carrying 100 amperes, might be evident at a distance of 19 miles. It becomes, therefore, important to decide to what extent disturbing influences can be eliminated. It is well known that if either the disturbing circuit or that disturbed be constructed of two wires so close to each other and so erected that the mean average distance between the disturber and disturbed is the same, no inductive effects are evident, for the influence on one wire is entirely neutralised by the equal and opposite effect on the other. But if this mean average distance is not equal, or if the equality of the two currents be departed from, then a disturbance will arise which will depend on the difference between the two currents and their relative distances. Hence the most perfectly silent telephone circuit becomes noisy when leaks occur in the insulation, and hence it is that the earth plays such an important part in the efficiency of the system.

It was reported in the technical papers that the London Electric Supply Corporation contemplated laying a concentric conductor between Deptford and London, with the external copper conductor in contact with the earth. As it seemed to the Post Office authorities very doubtful whether such an arrangement would be free from disturbance, experiments were made to test the point. The experiments were made by me in an open space of two or three acres in extent. A concentric cable was constructed so that the outside and enveloping conductor could be insulated or not. The inner conductor was composed of a strand of 19 No. 15 B.W.G. (72 millimetres) copper wires. The outer conductor completely surrounded the inner, and consisted of 24 No. 16 B.W.G. (65 millimetres) copper wires. Each conductor weighed about 1,600lb. per mile, and gave a resistance of ·56 ohm. The outside sheath was of lead The following (Fig. 1) is a full-size section of the cable :—

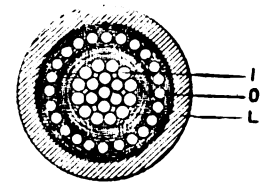

FIG. 1.

The following diagram (Fig. 2) will explain the arrangement of the wires :—

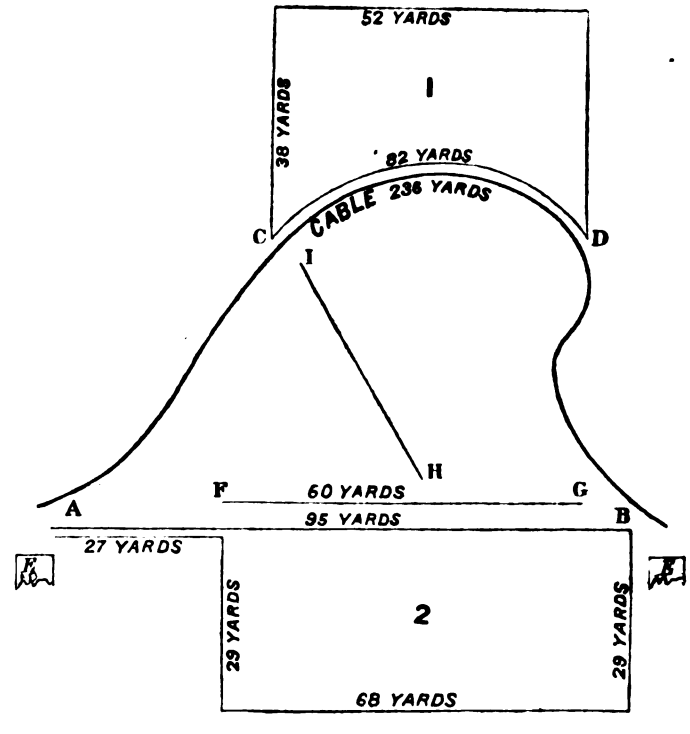

FIG. 2.

Two earth-plates were buried at the points A and B, and between them a No. 7 gutta-percha wire was laid along the ground, telephones being inserted at each end. The electric light cable was laid between the same points by a circuitous route, as shown. At the points C and D two earth-rods were driven in, and another No. 7 gutta-percha wire was laid outside the area enclosed by, and about a foot from, the cable.

Beyond each of the gutta-percha wires extension wires were carried to enable metallic loops to be made up, forming approximate squares (1 and 2 on diagram).

Experiment No. 1.—A Wheatstone transmitter placed at B was connected to the inner conductor (I) of the cable, the lead sheath (L) being used as the return wire. Reversals at top speed (a frequency of 80 per second) were sent through the cable from an E.M.F. of 20 volts, the current strength being about 1·3 amperes.

* Paper read on Thursday, 28th March, 1889.

Digitized by Google

Loud disturbance was heard in the telephones at A and B when the transmitter was running.

Experiment No. 2.—Earth-bars were driven in at the points F and G, and connected by a wire and telephone. Currents were picked up by the telephone through this section, their effect being apparently quite as loud as between A and B.

Experiment No. 3.—The points H and I were similarly connected, and with a like result.

Experiment No. 4.—The points C and D were next connected by the wire attached to the earth-bars, a telephone being inserted at D. Disturbances almost as loud as on the circuit A B were heard.

Experiment No. 5.—The wire C D was disconnected with the earth-bars, and a metallic circuit forming an approximate square was made up (1 on diagram). The interference was still heard, but was only about half as loud as when the earth was used at C D.

Experiment No. 6.—The insulated outer *conductor* (O) was substituted in place of the lead sheath as the return wire, and the disturbances in the loop C D ceased entirely.

Experiment No. 7.—The outer conductor (O) and the lead sheath (L) were coupled together, forming jointly a return wire in contact with the earth. The disturbance in the metallic square 1 reappeared, but was reduced in loudness to about half that in the fourth experiment.

Experiment No. 8.—The cable was next laid out straight from A to B, the telephone wire being parallel to it. When the lead sheath was used as the return wire loud disturbance was heard in the telephones at A and B. When the lead sheath and outer conductor were jointly used as the return wire, the noise in the telephones was greatly reduced (to about one-fourth).

Experiment No. 9.—To prove that the result obtained in the last experiment was due to earth conduction, a metallic square (2 in diagram) was formed, and the disturbance in the telephones disappeared.

It follows from these experiments that the disturbance of the potential of the earth at A and B, and the establishment between these two points of a potential difference, causes currents to flow through the earth between A and B which destroy the equality between those in the inner and outer conductor of the concentric cable upon which equilibrium depends. It is therefore quite clear that the use of the external sheathing as part of the conductor in contact with the earth is quite out of the question; whereas if the enveloping conductor be insulated it is quite innocent of disturbance, and would not interfere with neighbouring telephones.

The question has arisen as to whether the currents experimented with (viz., those produced by a Wheatstone transmitter) are of the same character as those produced by an alternating-current machine. The frequency in the two cases may be alike. Taking the frequency at 100, it will follow that each current, whether it be of the Wheatstone transmitter or of the alternating-current machine, will rise from zero to maximum and fall from maximum to zero in ·0025 second. The strength of current generally used in the Wheatstone transmitter is 50 milliamperes, while that of an alternating-current machine may amount to 100 amperes; and since most of the Wheatstone circuits in this country are long circuits, upon which the resistance and the capacity are considerable, it is quite evident that in actual practice the rate at which the current rises and falls is greater in the case of alternating-current machines than in the case of the Wheatstone transmitter. The fact that it is so is sufficiently proved in actual practice. Before the Grosvenor Gallery Company established their metallic loop system, all the telephones around and about Bond-street were disturbed. In order, however, to settle the matter, I have carefully experimented with the currents produced by the alternate-current machines at West Brompton and at Eastbourne, and I find that it is quite impossible to detect any difference between the effects of Wheatstone transmitters and alternating-current dynamos.

These experiments, taken alone, are sufficiently definite to render it decisive that the use of the earth in such instances cannot be allowed; but it may happen that in other systems of distribution where the currents are continuous and steady, such as the systems by which it is proposed to distribute by means of batteries, the earth under exceptional circumstances may be permitted.

The Royal Society.—The following Papers were read yesterday (Thursday) afternoon at the Royal Society:—"The Magnetic Inclination, Force, and Declination in the Caribee Islands, West Indies," by Prof. Thorpe; "Experiments on the Resistance of Electrolytic Cells," by Capt. Sankey.

THE WIRING OF BUILDINGS FOR ELECTRIC LIGHT.*

BY J. D. F. ANDREWS.

The first points for consideration in devising a wire system for electric lighting are, what contingencies will be met with that will affect the system, and what faults will arise in it after its introduction.

Through past experience it has been found that the practical pressure of electricity for electric lighting is (within 50 per cent. either way) about 100 volts, the 100 volts being most generally adopted. The chosen conductor is copper, and the most widely adopted insulation is India-rubber: in many modified forms the insulated conductors are usually protected and held in position by wooden casing. One object of insulation is to protect the wire from the evil effects of moisture, which sets up chemical action in the conductor. The result of the electrolytic and chemical actions on electric light wires is to thin them and make them insufficient for carrying the current, and consequently they become heated; this may even lead to the rupture of the wire causing an "opening circuit." This effect is about the most difficult and dangerous fault to contend with. It is usual to lay the electric light leading wire in a groove in the casing neighbouring and parallel to the return wire. Water often saturates the casing between them, and when the insulation is poor the electricity will pass through the moistened wood and char it, often setting it in flame. Faults such as this, where a great leak is taking place between the wires, are called "partial short circuits," and are equally difficult to avoid, and as dangerous as opening circuits. The study of the insulation of the wires is therefore obviously of great importance. Most of the results in good insulation were obtained by telegraph engineers before the electric light business was started; but in the new business these results were almost entirely ignored. Great insulation was then not considered necessary, and special covering for the wires was devised of a cheap and poor quality, which, it is greatly to be regretted, has continued in use by many contractors to the present day. As previously stated, India-rubber is the base of the insulation of most electric wires—the purer the material the better the insulating properties—but pure India-rubber is easily influenced by air. At first it gets hard, and in course of time changes to a soft, sticky state, when it is useless as an insulation. Pure India-rubber is still the foundation of insulation on the wires, but in the very best qualities it is protected from the atmosphere by an outer coating of what is known as vulcanised India-rubber. Such qualities of insulation consist of, first, one or two lappings of pure India rubber, then a layer of India-rubber mixed with such minerals as soapstone, over which again is laid a coating of rubber, mixed with a large proportion of sulphur. The wire, with its three coatings, is now subjected to a high temperature in a vulcan by means of steam, through which the rubber and sulphur combine, while any surplus is absorbed by the middle coat, which is called the separator. Such is the insulation of the best quality wires. The inferior qualities, and those most generally used, are insulated simply with pure rubber and cotton serving, with ozokerite or other compound tape laid together in many different ways, according to the device of the makers. The compound tape is supposed to protect the pure rubber from the air, but it only plays this function to a small extent. The usual *reliable* life of such wires is from two to three years; and not being reliably waterproof throughout their length at any time, there is always danger of failure through moisture. Vulcanised India-rubber covered wires of the class above described—there are many inferior kinds—is perfectly reliable in water or air for a great number of years.

The next contingency that has to be contended with is mechanical damage. The wires being more or less flexible and the covering soft, they are easily damaged. This difficulty is usually met by casing the wires in wood. Wood casing has the disadvantage of harbouring moisture. Another method of protecting the wires is that of sheathing them with an outer covering of wire, as introduced by the writer some years ago in ship lighting. This method protects the wires much more effectually than casing, and does not harbour moisture. Iron pipes have been used in many cases, and are an excellent protection; but moisture collects in them, and if there should be a fault in the insulation it is sure to find it.

There is another fault besides the opening circuit and partial short circuit not yet touched upon, namely, a dead short circuit, or a direct contact between the opposite conductors. Short circuits usually happen in the fittings when the opposite conductors are necessarily brought nearer each other, and at these points the insulation is generally much thinner and poorer. Short circuits also often happen where the wires cross, frequently by contact with gas or water pipes, which make very complicated faults, because the two wires usually touch the pipes a distance apart, which will be better understood by reference to Fig. 1. Suppose the current to leave the dynamo by the positive wire, pass to the lamps by the branch wires, and

* Paper read before the Philosophical Society of Glasgow, March 20th, 1889

Digitized by Google

back by the negative branch wires through the fuse F and the negative main to the machine. Suppose, now, the positive branch becomes connected to a gas-pipe at, say, A : this would not indicate itself in any way, and the installation would of course continue working just the same until the opposite wire got connected to the gas-pipe, say at B. Now the current will become excessive—more than the branch wire can carry without getting dangerously hot—before the main fuse T melts. In the above description it is assumed there is a safety fuse at F, but it will be observed the short circuit has bridged the wire in which it is inserted, and it is consequently useless. To avoid the excessive heating of the wires with such faults as above referred to, it is necessary to have fuses one on each wire, such as at F and S. Under such circumstances, when a short circuit such as described between A and B takes place, the fuse S would immediately blow and prevent danger. Let us again assume there are fuses on only the negative wires, we will see there might have been even a worse fault. Again, supposing a connection at A with the gaspipe, which is, of

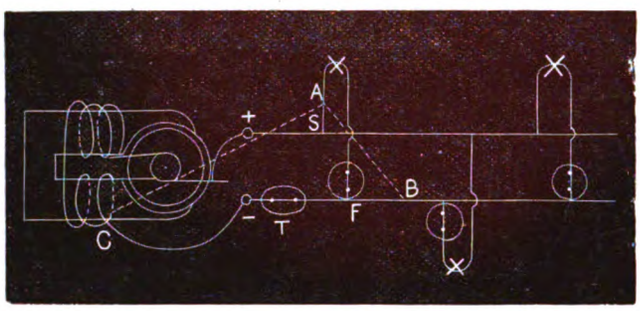

Fig. 1.

course, connected to the earth, we will assume the second connection to take place in the dynamo field-magnets at C. The current will now traverse the positive wire to A, thence to the gaspipe to earth, and back to the dynamo. This route is a short circuit, and one moreover that bridges both branch and main fuses, which we have assumed to be only on the negative wire, as is still the practice of some contractors. The consequence of this short circuit is similar to the one from A to B, but worse, because there are no fuses at all left to protect the system. Of course with another main fuse on the positive wire such a short circuit could not continue.

There is, however, objection to the multiplication of fuses ; they are a danger themselves sometimes, such as in the case of a partial short circuit that does not increase the current sufficiently to melt the fuse, but quite sufficient to heat it to a degree dangerous to any inflammable material in the neighbourhood, and it may continue in this condition some little time before it fuses, especially if it is a large one. Another point of danger from a fuse is that when it melts it throws out sparks of molten metal. Of course it will be said that the evils in fuses can be reduced by proper construction. That is true ; but it is decidedly better to avoid, if possible, numerous points of danger in an installation resting on special construction or the care of an attendant for their prevention. We will consider later how this to a certain extent can be achieved.

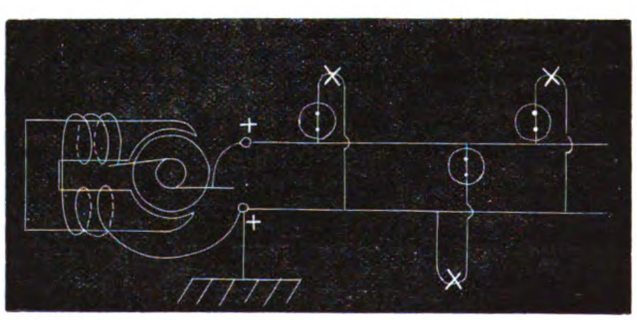

Fig. 2.

In the foregoing we have considered mainly the contingencies or dangers arising from the introduction of electric light into buildings, and we may summarise the main points as being an opening circuit, a partial short circuit, a dead short circuit, and the fuses. We have considered the dead short circuit to be met by the fuse, although a new element of danger is introduced, which, however, is much less in degree. This new element of danger can be reduced to one-half by connecting one of the leading wires, say the positive, to the earth and the gas and water mains, it being only on account of the latter that it is otherwise necessary to provide a fuse on each wire. Fig. 2 will show this more plainly. The current leaves the dynamo by the positive terminal, and meets at once a connection to earth and the gas and water mains, then proceeds by the positive wire to the lights and back to the dynamo. This connection to earth is wilfully effecting the fault we supposed might happen, as in Fig. 1 ; but in making the connection to earth we are careful to do so with that wire which has not got the fuses inserted in it, which is contrary to the action of the fault in Fig. 1. Now, if any of the negative wires come in contact with the gas and water pipes a fuse must instantly blow as if the two conductors themselves had touched. All the electric light fittings would in this case be connected with the positive wire, the negative wire passing down the centre of the

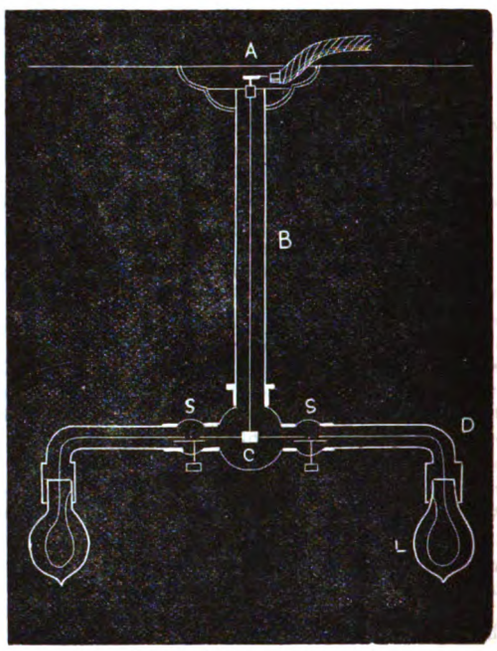

Fig. 3.

tubes. There being in the fittings only a single wire which can be heavily insulated and made stouter, there is an additional safety against short circuits, or fuse melting, besides the very great advantage of being able in a very simple way to wire each part of an electrolier or fitting. Fig. 3 illustrates how this is effected. The current travels from the contact A down the wire B, through the contact C to the switches S S, by the wire D to the lamp L, and back by the brass of the fitting to the ball and socket at the top, and away by the earth wire. The wire inside the tubes is never smaller than No. 14 S.W.G., and the contacts are made with a strong small spiral spring. The contact at the ball and socket joint projects through, and being a box spring it gives and takes with the swing of the fitting, and scrapes on a fixed brass plate in the roof plate. Single or universal joints are quite simple to construct with this system within the same dimensions as for gas, whereas with the two wires passing through the fitting this is impossible. This method of connecting one of the wires to earth is best called the earth system ; it is, however, often called the single-wire

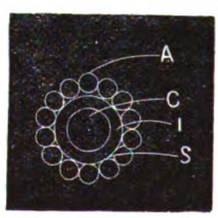

Fig. 4.

system, because in its application to ships the hull of the ship is used as the return wire. In buildings, however, two conductors are required, and as it is important always to be able to distinguish between the negative wire in which the fuses are inserted and the positive wire which is connected to earth and all the electrical fittings, the positive wire is coloured red and the negative wire black. The object of connecting the positive wire to earth is that red coloured wires are usually inferior in insulation quality to black wires, and it is not so important that the return or earth wire should be so highly insulated as the leading wire.

Digitized by Google

We now come to the consideration of means for minimising those most dangerous faults opening and partial short circuits. Except the means proposed by the writer in the following paragraph, no attempt has been made to treat these faults except by good workmanship and material. The proposal the writer makes is to universally adopt the sheathed or armoured wire system devised by him some years ago for use in the exposed and damp places on board ships, using the earth-wire system, and now extensively employed for that purpose. The virtue of this system is that all faults, partial short-circuits, and opening circuits, are reduced to dead short circuits. Fig. 4 is an enlarged section of an armoured wire such as is now in use; C is the copper conductor. It is covered with vulcanised India-rubber insulation of the highest class, with a serving of jute and special compound between it and the iron armouring A, which is a great many times larger in cross-section than the copper conductor. Care is taken that it is always more than seven times larger, this being about the difference in electric conductivity of the two metals. It will be understood that the copper wire is the lead and the iron wire the return. It was assumed in devising this system that an opening circuit in the outer conductor was very unlikely to take place, and so it has been found in practice; it is, however, possible that the inner conductor, through undue strain or a flaw, might have an opening circuit in it, and if such were to take place the immediate result would be that the heat generated would destroy the insulation between the two conductors, and at once effect their fusion together and a short circuit. As a matter of fact, however, short circuits in this system have in practice been many fewer, and there have been no opening circuits or partial short circuits. How many of the short circuits were due to such faults is difficult to say; the causes of some were doubtful.

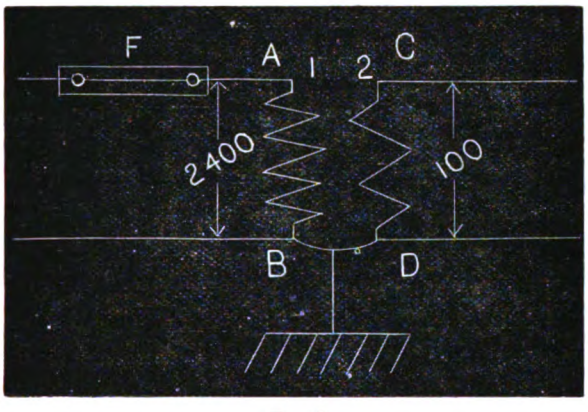

Fig. 5

The writer is not aware of any new danger or contingency being introduced with this system of concentric wiring, although he has heard that some people object to it, and in fact to any system in which an earth connection is introduced; but he has still to learn upon what grounds the objection is based.

In addition to the advantages above referred to, there is another of not the least importance. The electricity being entirely enclosed within the outer conductor, and the electric pressure being only from the centre point to the outer conductor, it is impossible to get a shock through anything more than a very small portion of one's flesh, such as the finger, except by wilful contrivance.

It is advisable before closing this subject to consider how a system of wires supplying a town would be affected by an earth connection of one of the conductors. With any system of supply embodying the series system, I may generally say it is not advisable to employ an earth. I have expressed this point broadly as it involves complex considerations which would take long to make quite clear. But with all systems on the parallel system there are many points favourable to an earth connection, some of which can be gathered from foregoing descriptions. It is more important for us to find out whether there is any objection to its use, and with this in view Fig. 5 is placed before you. It illustrates a transformer with its primary leads and an electric pressure of 2,400 volts at the terminals A and B, where they join the primary circuit 1 of the transformer. F is a fuse in the primary circuit; 2 is the secondary circuit of the transformer, between the terminals C D of which there is represented a pressure of 100 volts; the terminals B and D of the circuits of the transformer are connected to earth, and consequently connected together. The writer is unable to find any danger in thus connecting the 100-volt pressure circuit to the 2,400-volt pressure circuit. Nobody could get a shock to earth, because the pressure between the return wire and earth is reduced to *nil*. The next point is, is there any greater probability of the insulation of the transformer breaking down because the circuits are joined together at one end? This seems to the writer to be answered by a simple calculation; with the earth connection there is no pressure at one end, but all the pressure whatever it is at the other; with no earth connection the pressure is alike at both ends, but at each it is only half the total. The result in both cases is the same. Suppose a connection did get made between the terminals A and C in addition to the earth connection, why the 2,400-volt circuit would be simply short-circuited, and the fuse F would melt. There is, it is true, a very remote possibility of danger in the event of the great improbability of three circumstances happening in succession, viz., first of all, a connection between the terminals A and C as well as the earth, then the fuse F not melting, and thirdly, the circuit of the secondary of the transformer to open between the terminals, and thus put the 2,400-volts pressure on to the lamps direct, which would, as a matter of course, immediately gasp their last.

There is one other circumstance worthy of mention in favour of the earth connection. Should the wire system at any time be struck with lightning there is at once a safe connection to earth instead of having to pass through a highly insulating material as when there is no earth connection. Lightning has already been known to strike overhead electric light wires and discharge itself through the dynamo to earth, to the imminent danger of the machine.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, April 5th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "Moulding and Casting Cylinders for Marine Engines." By R. J. DURLEY, B.Sc., Stud.Inst.C.E.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"The Electrician" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and now makes over 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

Volume XXI. of "The Electrician" is NOW READY,

Price 12/6, post free 13/6.

Cases for Binding Volume XXI. are also Now Ready, Price Two Shillings, Post Free, Two Shillings and Threepence.

GOOD FRIDAY NOTICE.

In Good Friday week "THE ELECTRICIAN" will be published on Thursday morning (April 18th), instead of on Friday (April 19th).

Advertisements for this issue must reach the Publishing Office 1, SALISBURY-COURT, E.C., not later than Wednesday morning.

PARLIAMENT AND THE TELEGRAPHS.

The discussion on the Telegraph vote last week, and especially the statement of the Postmaster-General in regard to it, was of exceptional interest, marking, as they probably did, a turning point in the career of a State undertaking which until now has not been altogether a prosperous one. Mr. Raikes is peculiarly fortunate in being able to announce that the difficulties which have beset the financial welfare of the telegraph service during his predecessors' administration have been gradually overcome during his own; and still more happy in the acquisition of a new branch of its business at a cost far less onerous than that with which the inland telegraphs have been burdened since 1870. The present Postmaster-General, whatever else he may be, is certainly not a common type of the Parliamentary chief of a public department; but that he contrives to get on well with his permanent officials appears to be evidenced by the touching and grateful tribute he paid to the memory of Mr. Patey, the news of whose sudden and lamented death only reached him while the Telegraph votes were under discussion. To the firmness and vigour displayed by Mr.

Digitized by Google

RAIKES in defending the interests of his department is probably due this harmonious working with its permanent staff, whose undivided aim and duty are identified with its prosperity. Mr. PATEY lived to see the transfer of the Submarine Telegraph Company's cables to the State virtually completed, and we may take it that he was at one with his Parliamentary chief in the prolonged negotiations which preceded it. The bargain is not what the company expected; but so far as the British Post Office are concerned, they appear to have done their best with the other Governments to represent the Company's case fairly. More than this Mr. RAIKES does not pretend to have done. With his usual outspoken bluntness, he told the House of Commons that he would deal justly by the clerks and officers taken over by the Post Office, "but not more liberally than he was bound to." A similar determination appears to have guided him in dealing with their late employers, who, according to all we hear, have on their part displayed no greater generosity towards their old servants.

It is said that even at the reduced rates which came into force last Monday these Continental cables will repay their cost in less than a twelvemonth. Be that as it may, the proportion of revenue accruing to the British Post Office will be considerable, and probably quite large enough to more than cover the small deficit at which the Telegraph account now stands. With the steady progression under the sixpenny inland rates, and, supposing the European peace to be maintained, the certain growth of Continental traffic, the end of the financial year just commenced will show a substantial balance on the right side. Mr. RAIKES has almost pledged himself to this consummation; and his prediction is not likely to be falsified by any weak or sentimental yielding to public clamour for unremunerative concessions. On those members of Parliament who lectured him—Mr. HENNIKER HEATON was, of course, among the number—about conducting the business and stating the accounts on commercial principles, he retorted that he would be better able to do this if hon. members would refrain from demanding uncommercial privileges for their constituents. To the still more numerous class who have not even yet been cured of their passion for free addresses he held out no hope whatever. It is amazing that at this time of day member after member can get up in his place in Parliament and argue that the withdrawal of free addresses is a hardship which ought to be redressed immediately the telegraphs begin to pay their way. Such is the fact, nevertheless; and but for the firmness of the POSTMASTER-GENERAL, backed, to his credit be it said, by Mr. SHAW LEFEVRE, a fresh crusade against the settlement of 1885 would have been started. Happily, Mr. RAIKES was able to dispose of these gentlemen by pointing to a phenomenon of the word-tariff which has manifested itself in recent years on the land lines as well as on the cables, namely, the gradual diminution in the length of the normal telegram. From 1s. 1d. previous to 1885 the average price paid under the sixpenny rate fell to between 8d. and 9d.; but it has now fallen below 8d.—a fact which shows that the public, trained into habits of brevity, have learnt how to reduce the length of their messages so as to save their pockets. To make them a present of a number of free words under such circumstances would be simply a wanton waste of the Post Office revenue.

Against the abuse of free Railway service messages and the unremunerative rates permitted for Press messages there are more reasonable grounds of complaint. All that can be said on the other side is that these priviliges exist under agreements which it would not be easy to abrogate. As regards the Railways they are supposed to have given over to the Government an equivalent for their right to the free use of its wires at the time of the transfer of the telegraphs to the State nineteen years ago; but the increase of these messages tenfold during that period certainly calls for some explanation. Cheap Press messages were formerly thought to be one of the central objects of a general reduction of the tariff, the country newspapers being in that way placed on an equality with those of the metropolis. Mr. PICKERSGILL, who does not seem to like the news that is nowadays sent to the provinces, is a member for some metropolitan borough; if he represented a provincial constituency he would probably have no fault to find with the Press rates. Any way, it is absurd to say that the Post Office sustains a money loss equal to the price at ordinary rates of the free Railway messages and the cheap Press messages. If charged for at full rates, this portion of the traffic would be immensely cut down, and in the case of Press work would probably yield no more than it does at present. Most of it is done in the night time; and the proper way to deal with it, if it should grow beyond the capabilities of the service when ordinary traffic is suspended, is not to expend more money in expediting this unprofitable business.

A policy of the latter kind seems to have been acted upon for a long time past by the POSTMASTER-GENERAL in his dealings with the Telephone Companies, upon whose present and future business relations with the Post Office he was as emphatic in Parliament as he had been outside of it. The patents will soon expire, says Mr. RAIKES; and then it will be his duty to see that the public re-acquire those rights of which, he is at no pains to conceal, he considers they were deprived by the excessive generosity of his predecessor, Mr. FAWCETT. Meanwhile, he will not enter into bargains or arrangements with the Telephone Companies that might hamper him when the day of readjustment shall arrive. This probably explains why no action has been taken upon the offer Mr. BRAND, in his letter to *The Times* of Saturday, states that his company made to the Postal Authorities in 1885, to fit up a telephone on very liberal terms in every London Post Office. Mr. RAIKES leaves no room for mistaking his intentions with regard to the Telephone Companies, and for that small mercy at least we may perhaps be thankful. It is worthy of remark also that to this part of his statement nobody in Parliament openly took any exception.

OBITUARY.

CHARLES HENRY BENNET PATEY, C.B., M.S.T.E.

The brief announcement which it was our painful duty to make last week of the sudden and untimely death of Mr. Patey, the Secretary for the Postal Telegraphs, had only reached the Institution of Electrical Engineers in the course of its meeting on Thursday evening, March 28, where the intelligence created a profound sensation.

Mr. Patey was in the prime of life, and although not of strong constitution, having suffered from affection of the lungs since his youth, his natural vitality and energy of character, together with his lithe figure, active movements, and almost military bearing, gave the impression that he enjoyed excellent health. A few years ago he had an attack of inflammation of the lungs, so serious that probably he never quite recovered from it; and it was under a similar attack, after an illness of only six days, that he finally succumbed. Mr. Patey, like his eminent predecessor, Mr. Scudamore, had always taken great interest in the affairs of the Society of Telegraph Engineers, of which body he was a member, and for some years occupied a place on its Council. Son of the late Admiral Patey, C.M.G., Charles Henry Bennet Patey began his career as a public servant in the Secretary's department of the Post Office at the age of nineteen; and with the opportunities offered him in the transfer of the Telegraphs

Digitized by Google

to the Post Office a few years afterwards he displayed such marked ability that he soon assumed a position of prominence and responsibility. The retirement of Mr. Scudamore virtually placed Mr. Patey at the head of the Telegraph Service, and in 1877 we find him made an Assistant Secretary, from which rank he was promoted to be Third Secretary in 1882. Ever since 1887 Mr. Patey has been the Chief Postal Officer for the Telegraphs; and upon him devolved mainly all the negotiations and business relations with the Telephone Companies and with Parliament in carrying through the scheme of sixpenny telegrams. Latterly the acquisition of the Submarine Telegraph Company's property had taxed his energy and patience to the utmost, and he may be said to have lived just long enough to see the superstructure completed, the foundation of which he had assisted in laying more than twenty years ago. For his services to the State, and perhaps more particularly for those which he rendered at several International Telegraph Congresses, Mr. Patey received in 1886 the distinction of the Companionship of the Bath. He died in his 45th year, and leaves a widow and five sons. His loss is deeply deplored, not only by his family, but by his comrades in the Department over which he presided for so many years.

The funeral took place on Tuesday afternoon at Bromley Cemetery, Kent, in the presence of a large concourse of friends and colleagues of the deceased. Amongst the latter were the Postmaster-General, Sir Arthur Blackwood, Mr. Algernon Turner, Mr. Cardin, Mr. Graves, Mr. Preece, and several representatives of foreign telegraphs. Both Mr. Shaw-Lefevre, ex-Postmaster-General, and Mr. Jackson, Financial Secretary to the Treasury, had intended to be present, but were prevented from doing so by Parliamentary business. The procession was headed by a detachment of Royal Engineers, and by a guard of the Post Office Rifles, a large contingent of telegraph messengers in uniform, and officers of H.M. cable ship "Monarch." Amongst the floral offerings, which were very numerous, was a large wreath received from the French Telegraph Administration.

ECONOMICS OF PLANNING AND CONSTRUCTING ELECTRIC LIGHT AND POWER STATIONS.*

BY ALEX. P. WRIGHT.

(*Continued from page 574.*)

The estimates of cost of property, building, apparatus, and construction are all high, as also the cost of maintenance and running expenses, whilst the rates at present to be considered are low. This is a justifiable course, to provide amply for contingencies in construction and operation, and can be more closely considered when final and detail plans are elaborated.

It will be fair, for the present, to base the rates upon the A estimate, which allowed 4 per cent. for dividend in the first year of operation, more than would be expected in the majority of enterprises, and gives the actual cost for light and power as follows:—

	Per annum.
Full arc lamps, all and every night	$124.32
Divided arc lamps (commercial), average	35.27
Incandescent lamps (including renewals), average	6.94
Motors per horse-power actual	42.25
Motors per horse-power nominal	21.13

The rate for full arc lamps for street lighting may be fairly fixed at $127.75 per annum, or 35 cents per night for all and every night lighting, which is about the present average charge throughout the United States. The rate of $60.00 per annum or $5.00 per month for divided arc lamps could easily be obtained for the average commercial lighting.

The settlement of incandescent rates for various hours of lighting should come later, when more definite plans are decided upon, but an average of $9.00 per annum including renewals, whilst below the general average, would amply repay an investment under the conditions considered here.

The wisdom of including lamp renewals in the schedule rates of an electric light company is questioned by many, but it should be borne in mind that it is very difficult to satisfy the average consumer that any bill for extras above the contract price per lamp or the metered electrical energy supplied to him is not an extortion; and once consumers get such ideas into their heads a feeling will grow against electric light companies as unreasonable and rabid as that universally existing against the much abused gas company and its meter; besides, we are not proposing to enter into business to sell lamps, but light. Incandescent lighting at an average rate of $9.00 per annum for commercial lighting would be equal to gas at $1.00 per thousand cubic feet.

The motor rates being fixed at $45.00 per horse-power, which is considerably lower than that usually charged, the rates may be applied to the three cases, A, B, and C.

A. 60 full arc lamps at $127.75	$7,665.00
170 divided arc lamps at $60.00	10,200.00
4,380 incandescent lamps at $9.00	39,420.00
70 horse-power motors at $45.00	3,150.00
Gross income	$60,435.00
Gross expenditure	48,037.00
Net income	$12,398.00
Dividend 4 per cent. on $230,000.00	9,200.00
Surplus	$3,198.00
B. 120 full arc lamps at $127.75	15,330.00
200 divided arc lamps at $60.00	12,000.00
7,200 incandescent lamps at $9.00	64,800.00
140 horse-power motors at $45.00	6,300.00
Gross income	$98,430.00
Gross expenditure	54,576.00
Net income	$43,854.00
Dividend 12 per cent. on $230,000.00	27,600.00
Surplus	$16,254.00

When the plant as first installed becomes loaded to its full capacity it will become necessary to increase the boiler, engine, and dynamo capacity, and the outside construction, some of the latter necessarily being done more or less at all times. Say that with the surplus and $20,000.00 additional capital, bringing the total capital stock to $250,000.00, the building as provided would be filled to its full capacity as provided for in case C, under which circumstances if the rates were maintained as before the following would be the result:—

C. 300 full arc lamps at $125.75	$37,725.00
350 divided arc lamps at $60.00	21,000.00
8,760 incandescent lamps at $9.00	78,840.00
160 horse-power motors at $45.00	7,200.00
Gross income	$144,765.00
Gross expenditure	86,450.00
Net income	$58,315.00
Dividend 12 per cent. on $250,000.00	30,000.00
Surplus	$28,315.00

Before this point is arrived at the rates might reasonably be reduced to such a basis as to leave sufficient surplus to pay for proper maintenance of the plant in first class order, and leaving something for a reserve fund to be drawn upon in case of unforeseen contingencies, or to make such improvements as the future development of electrical apparatus may warrant.

The rates settled upon, whilst considerably lower than the average at present obtained, are ample under the circumstances described, and in many instances where coal was lower could be reduced with advantage, as low rates will always bring a large business, and would at the same time offer very little temptation to municipalities operating their own lighting service.

Before proceeding to consider the detail of planning and constructing it will be well to carefully determine the lines upon which the work should be carried on, and even at the risk of accusations of repetition it is proposed to reiterate and amplify the remarks made in introducing these articles.

In the first place avoid parsimony, and do not mistake parsimony for economy, and wherever the temptation comes to cut the cloth look back and see what it has been determined liberality will do in the shape of dividend production; many people with a 25-cent piece in their eyes fail to see the 20-dollar gold piece within easy range of their vision. Remember that any departure from the lines laid out, even to a small extent, may upset the whole plan, and that a plan once made it will be better when fairly on the way, as a rule, to carry out. Remember also in making contracts for machinery and material that any of the good and well-known firms will supply good apparatus, and do not pay heed to those who tell you that their competitors' goods are worthless, or guarantee fairy-like results, but having voted or decided upon a certain expenditure for your work do not attempt to make money out of it—that is not the purpose for which you started. Did you not commence with the intention of making money out of the operation of the

* From *Modern Light and Heat* (Boston, U.S.)

Digitized by Google

finished plant? Leave the settlement of the details of construction and purchase of materials to your engineer, and when construction is completed, the operation of your plant to your superintendent. Many appear to expect to obtain the highest quality for the lowest rate—they don't really believe so, but try it on. Bear well in mind that if there is any class of work requiring first class material, stability and durability, it is that required in an electric light station operated as it is or will be eventually for twenty-four hours a day, each day in the year. Having chosen your engineer leave him to present plans and specifications for discussion and abide by his judgment, or at all events, if you are not certain on this point, do not attempt amateur electrical engineering on your own part but call into consultation with him some expert engineer.

If now prepared to proceed it will be well to determine the systems of lighting and power to be adopted, particularly the incandescent system. The differences in the principal arc systems are not sufficient at this point to delay the preparation of the plans, which will in most instances suit any system. The determination of the incandescent system as between an alternating and a direct current system is almost necessary at this point.

For the sake of example suppose that an alternating system has been determined upon, being most suitable for the case under consideration. The number and sizes of dynamos to be installed should be determined, and where possible they should be of as large capacity as possible, for economy of space, for efficiency, and for economy in belting, pulleys and shafting. If the number of lamps in circuit does not vary, the largest dynamos are as a rule advisable, as they are proportionately economical to install.

The capacity of 2,000 candle-power lamps to be provided having been determined on the basis of schedule of lighting B, we find to be 120 lamps—60 for immediate use and 60 for future increase. Two 60-light machines or three 40-light machines would answer the purpose, and perhaps it would be wise to determine upon 40-light machines for the present at all events, in which case two 40-light dynamos would be ample for immediate wants with a liberal margin, leaving the third to be installed later. The determination of the sizes of divided arc dynamos requires more careful consideration, and will depend somewhat upon the variation in the number of lamps burning at various hours and periods during the year.

The divided or commercial arc lamps being used to some extent irregularly, the units of dynamo capacity, or at all events some of them, might be smaller. There are 170 lights to be installed immediately, with provision for 200. There will be times when only a small number of lamps may be required after eleven o'clock during the week, in concert rooms or halls, or for special lighting at night, and on Sunday evenings during church hours—say a load varying from 15 to 20 lamps, for which purpose, say, a 20-light machine be adopted. If the 1,200 candle-power curve lines in the figure already used are followed, it will be concluded that 45 or 50-light machines might be used, say, four 45-light dynamos, with which and the 20-light dynamo any desired combination could be arranged to suit the variations of load likely to occur.

Considering the curves again, the incandescent dynamo capacity may be divided as follows, to allow for economical combinations for varying loads, viz., one 500 or 650-light machine, two 1,500-light machines, and 3,000-light machine. The economical subdivision of machine units will always depend in a great measure upon the variations in the incandescent load, and should be as large as possible for obtaining economical results; but some consideration should, of course, be given to subdivision, irrespective of economy, in order that in case of accident only a portion of the lighting is affected, or better still, if possible, as is done in this case, spare machines should be provided. The motor generator we have deemed it wise to choose of the ultimate capacity, namely, 80 horse-power.

(To be continued.)

THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 23rd ult., a Paper was read by Prof. THRELFALL on

"The Measurement of High Specific Resistances and the Measurement of the Resistance of Imperfectly Purified Sulphur."

The author has been investigating the insulating properties of some of the New South Wales gums. As he finds that none of the gums tested would be of any practical value as insulators, he does not give the actual results attained. The Paper on the "Resistance of Impure Sulphur," however, gives the results of the measurements, being given as an illustration of the method rather than on account of the value of the actual results. The measurements were made by obtaining equal deflections of a resistance galvanometer—first, when a known fraction of the E.M.F. of a Clark's cell was made to act through a megohm in the galvanometer circuit; second, when the E.M.F. of a known number of compared Clark's cells were made to act through a layer of the substance placed between parallel plates of conducting material.

The apparatus employed is shown in the accompanying illustration, Fig. 1. It consists of two thick rectangular brass plates, scraped flat on one surface until one plate would lift the other when placed in contact with it. The upper plate is furnished with a handle something like the handle of a flat iron, loosely attached, so as to cause no distortion when unequally heated, and is pierced by three holes, through which pass micrometer distance screws. In the final arrangement adopted, in order to overcome the difficulty of withdrawing the screws from the gum their centres were bored out and gold-plated copper rods passed through them, and keyed to them until it was required to remove them, the ends of the screws themselves remaining nearly flush with the lower surface of the upper plate. Indices similar to those used in spherometers were fixed to the upper plate, one to each screw. The plates were then platinised by "Roseleur's Process," having been previously prepared by heating to the temperature of boiling water and rubbing the scraped surfaces with a solution of caustic potash, finishing up with fine pumice stone dipped into dilute caustic potash. The author states that he has found this by far the best laboratory method for preparing metallic surfaces for electro-plating. The parallelism of the plates was secured by cementing the plated surfaces with hard paraffin and then screwing brass lugs to each plate, the lugs being brought

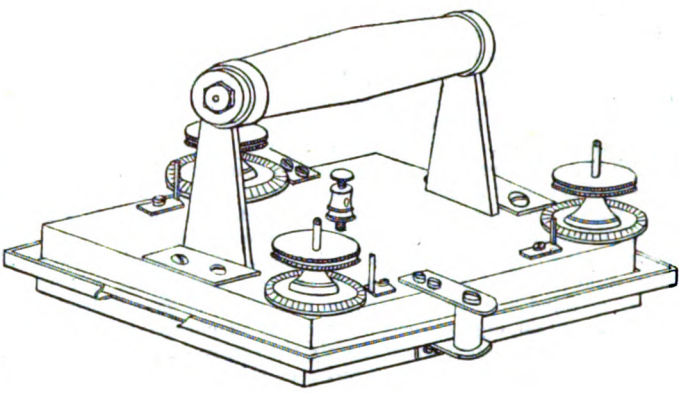

FIG. 1.

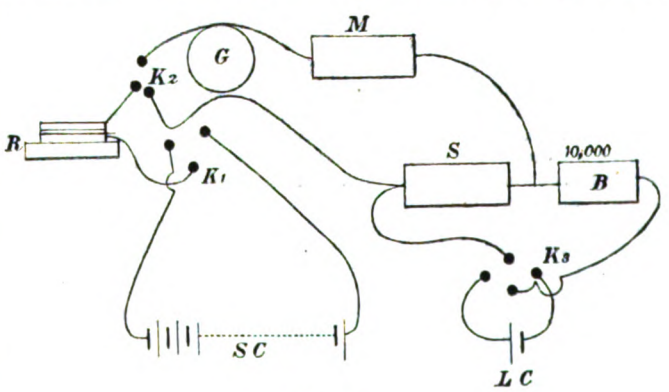

FIG. 2.

as near as possible without danger of contact, after which they were bored to fit slightly conical steadying pins. A rim was then screwed to the lower plate to make it into the form of a tray. In order to prevent deformation from the outer portions of the brass plates being in a different state of strain from the interior, they were cast of about twice the thickness required and the outer surfaces planed off. The positions of the screws when just in contact with the lower plate were permanently marked on them. In order to make a measurement, the plates were adjusted to the desired distance by turning the screws through a known number of turns, and the gum was melted in between them, every precaution being taken to ensure the absence of air bubbles, and the plates were allowed to cool very slowly to obviate any possibility of distortion. The steadying pins were then taken out, and the apparatus was ready for use.

The general arrangement adopted in making the measurements is shown in the diagram (Fig. 2). By means of a key, K_1, a current could be sent in either direction through the resistance R to be measured, and the galvanometer G. S C is a battery consisting of

Digitized by Google

a suitable number of small Clark cells. L C is a large Clark cell. The E.M.F.s of these cells were observed during an experiment by means of an auxiliary galvanometer and balance arrangement not shown in the diagram. By means of the key K_2 the resistance arrangement could be put in communication with the last cell, so as to charge up without allowing the current to flow through the galvanometer. After charging, the connections were altered so as to allow the current due to leakage through the substance under test to flow through the galvanometer. The E.M.F. of the small cells was not altered by this amount of leakage, and the fall in that of the large cell was measured in the ordinary manner. Plugs were taken out of the resistance box S until the galvanometer gave the same deflection whether the current were sent through by the battery S C through the substance under test, or by the adjustable fraction of the E.M.F. of the cell L C through a megohm. The sum of the resistances R and S was always 10,000 legal ohms.

Since it was advisable to use thick layers of the substance to be tested in order to diminish the experimental error in measuring the thickness, it was clearly of importance to have a galvanometer of the highest possible sensitiveness, especially since the smaller the E.M.F. the greater was the accuracy with which it could be determined. The experiments made by the author in this direction are of considerable interest and value. His first experiments were made with a galvanometer of 9,000 ohms resistance, made by the Cambridge Scientific Instrument Company, and he found that for currents reaching the value of 10^{-7} amperes, the torsion was of great importance, and by increasing the fibre to 12 inches in length the sensitiveness was increased about fifty-fold. The next step was to obtain a more perfectly astatic system, and to reduce the weight of the mirror. The magnets consisted of discs of steel stamped out of a sheet of the thickness of writing paper subsequently hardened. A piece of aluminium wire of the right length was flattened at the ends, and a pair of discs, selected for their flatness out of a large number, fixed at each end on opposite sides by means of shellac varnish, thus making the wire much more exactly the centre of rotation than in the ordinary arrangement. A piece of the thinnest possible glass, cut out of a sheet previously tested for flatness, was then cemented on to one of the discs by means of slow-drying white paint which the author prefers for this purpose. The two pairs of discs were then magnetised at the same time by means of two small electromagnets which had been constructed with the most elaborate precautions to ensure the utmost possible equality. The two electromagnets were connected in multiple arc, and excited by the same current. The author found that the paint on drying slightly distorted the glass, but it happened to bring it into the form of a vertical cylinder, which gave a good spot of light at a distance of about 3 metres. With a galvanometer of this sensitiveness great care must be taken not to bring the controlling magnets nearer than is absolutely necessary to the suspended system, and to employ only very weak currents. The silk suspension was ultimately replaced by a quartz fibre 85 centimetres in length, owing to the trouble from change of zero due to the silk. A good deal of difficulty was experienced in getting the steel discs forming the magnets exactly into the same plane, but this was finally accomplished so satisfactorily as to bring the period of swing up to 30 seconds. In using this galvanometer the ventilation of the room had to be closed to get rid of air currents, and the galvanometer, cells, resistance boxes, and connecting boxes had to be insulated by resting on paraffin supports. The galvanometer was similar in its general construction to the one illustrated in the preceding Paper. (See *The Electrician*, Vol. XXII., page 590.)

Such an instrument can only be used in a tolerably non-magnetic laboratory and one which is exceptionally free from vibration, and the author found that in spite of the room having a concrete floor resting on twenty feet of broken stone, and the instruments being supported on slate benches, the best results were obtained at night and on Sundays. He considers that there should be no difficulty in constructing an instrument on these lines which should have a sensitiveness of 10^{-13} amperes per scale division, but he thinks that a quartz fibre six feet long should be used. A silk suspension would be out of the question as the zero would be continually on the move. The mirror, he says, should be good enough to be used in a telescope: the base of the instrument should be of gunmetal, and all the framework of metal.

In the discussion which followed the reading of the Paper, Mr. Boys said that he had found in constructing his radio-micrometer that the best method of attaching very thin glass mirrors was to cement them to capillary tubes of the thinnest glass by means of a mere speck of shellac varnish. He did not consider it at all necessary to use a quartz fibre six feet in length, which would, of course, be most inconvenient. By using a sufficiently fine fibre, it need not be more than 15 inches long. He stated that he had obtained quartz fibres $\frac{1}{5000}$ of an inch in diameter, and they would support a weight of two grammes, which was much more than was required of the galvanometer fibre.

RELATIVE AMOUNTS OF VOLTAIC ENERGY OF ELECTROLYTES.*

BY G. GORE, LL.D., F.R.S.

In this research the author has determined by means of the "voltaic balance" the relative amounts of voltaic energy of upwards of 100 aqueous solutions of elementary substances, acids, salts, bases, organic substances, &c.

The method of measuring was as follows:—Take two small glass cups containing known volumes, say half an ounce, of distilled water. Form two voltaic cells of them by means of strips of unamalgamated zinc and platinum. Connect them in series with a sensitive galvanometer of from 100 to 1,000 ohms resistance, so that the currents oppose each other, and the needles are not deflected. This arrangement constitutes the "balance," and is extremely sensitive to change of chemical composition of the liquid in one of the vessels. Make an aqueous solution of known strength of the substance to be measured, and add it in small quantities at a time to the water in one of the cups until the galvanometer needles visibly commence to move, and note the proportion of the substance to the water then contained in that vessel.

As the amount of energy required to move the needles is the same in all cases, the numbers thus obtained with different substances represent the relative amounts of voltaic energy of the substances. And as each substance or mixture gives a different number, it is possible by this method to detect substances, to ascertain their strength, and whether they contain impurities, or have changed in chemical composition. In many cases the method is an extremely sensitive one.

The author has arranged the results in the form of a volta-tension series of aqueous electrolytes, commencing with chlorine, which gives a plus number of +1,282,000,000, and ending with potash, which gives a minus one of −270,985.

ON THE LOSS OF VOLTAIC ENERGY OF ELECTROLYTES DURING CHEMICAL UNION.†

BY G. GORE, LL.D., F.R.S.

In this research the author has shown by suitable examples of measurement of the voltaic energy of different solutions by means of the "voltaic balance" (see *Roy. Soc. Proc.*, Vol. XLIV., pp. 151, 294, 300-308) the successive losses of energy which occur with every additional degree of complexity of a chemical compound. The following are some of the instances given:—

Energy.	*Energy.*	*Energy.*
I ..... =3,310,985	Br... =81,022.500	Cl ..... =1,282,000,000
KI ..... =16,361	KBr..... =66,909	KCl ..... =699,803
KIO^3 ..... =468	$KBrO^3$ ..... =364	$KClO^3$ ..... =239
		„ +KCl ..... =53
		„ „ +$Am^2C^2O^4$=28·4

KCl.	= 699,803
NaCl.	= 207,589
„ + KCl.	= 5,959
K^2SO^4	= 2,274
Na^2SO^4	= 2,020
„ + K^2SO^4	= 112
„ „ + 2 NaCl.KCl.	= 41
„ „ „ + 4 K^2CrO^4	= − 225
„ „ „ „ + 8 K^2CO^3...	= −11,435

In all the cases every addition to the degree of complexity of the definite compounds formed was attended by a large decrease of voltaic energy, and the relative amount of electro-negative energy varied inversely with the degree of molecular complexity of the substance.

ARC LAMPS AND THEIR MECHANISM.*

BY PROF. SILVANUS P. THOMPSON, D.SC., M.I.E.E.

(Concluded from page 600.)

It would be impossible, in the scope of this Paper, to dwell on the *hydrostatic feeds*, on the various modes of producing *vibrating feeds* and *hammering feeds*, which have been from time to time suggested. The notion of having a *continuous* feed, the rate of which should be varied as required, is an enticing one, but it has never been made a practical success. Neither have the periodic methods of feeding, at which Mr. Brockie made so brave an attempt in 1881; the flavour of which indiscretion still clings about him, in spite of the admirable lamps which he has produced in later years. Mr. Brockie's various forms of arc lamp would indeed well illustrate the whole range of the subject, and the same thing might be said about the numerous successive types of lamp produced by Mr. Crompton. Mr. Brockie has lately produced an excellent little projector lamp for use in the optical lantern, having the negative carbon pressed by spring against abutment screws of steel, whilst the upper carbon is fed forward by a nipping lever controlled by a solenoid. *Abutment* lamps and *projector* lamps form separate classes by themselves, which cannot here be discussed.

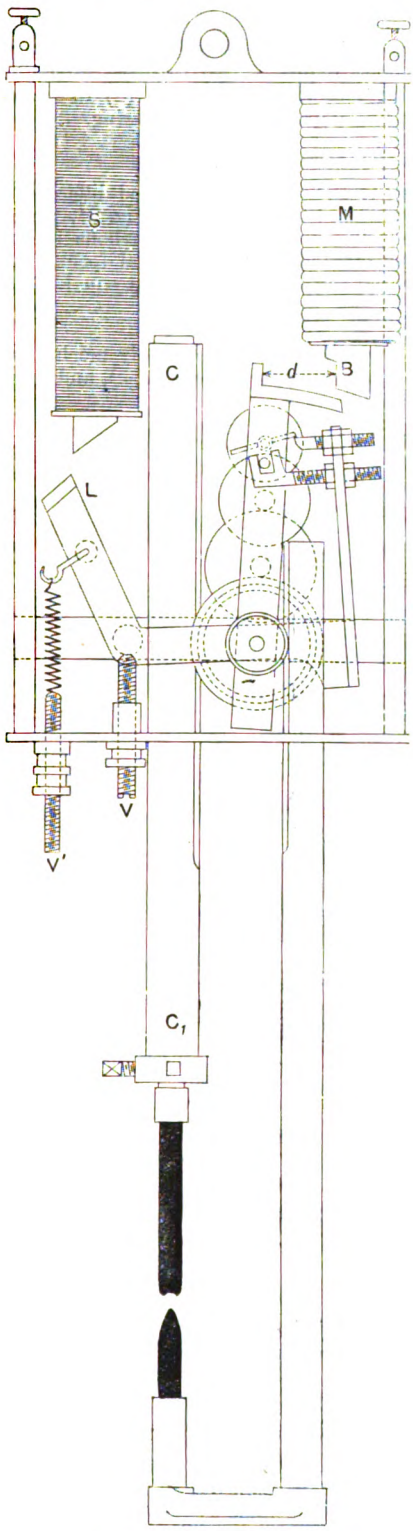

FIG. 23.—De Puydt's Lamp.

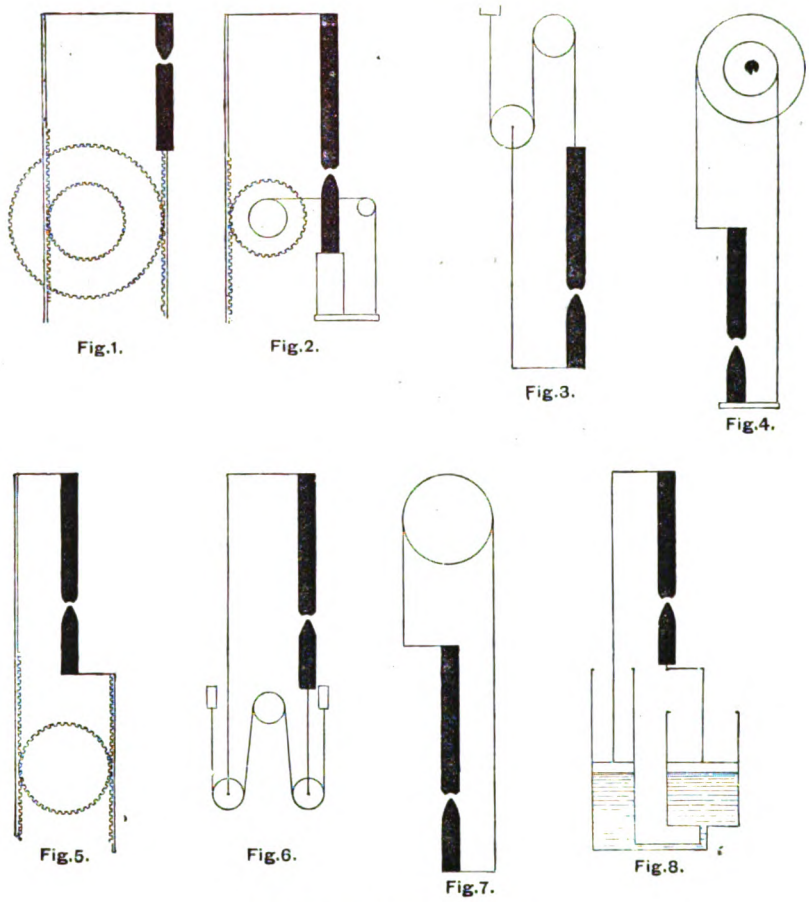

FIG. 24.—Modes of Focussing.

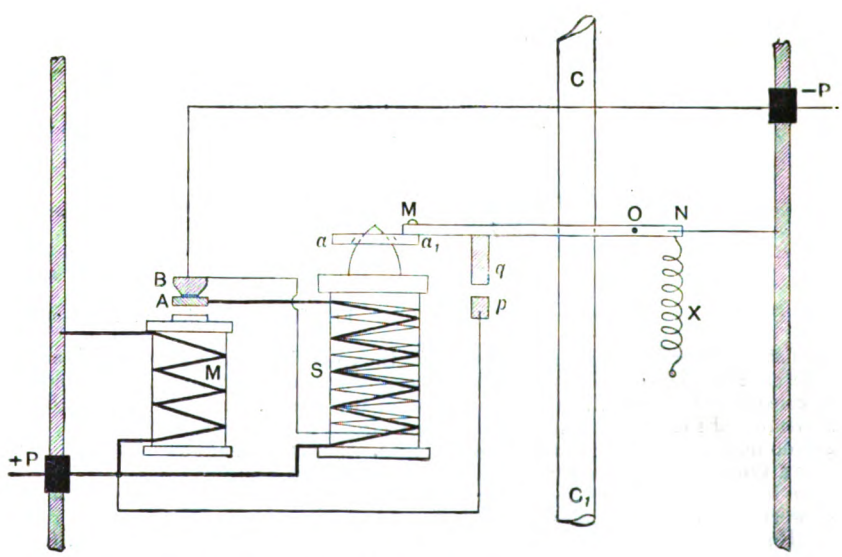

FIG. 25.—Circuits of Thomson-Rice Lamp.

Many of the points alluded to in the preceding descriptions are illustrated by the action of the De Puydt lamp, Fig. 23. This is a rack-train lamp which strikes its arc by lowering the lower carbon and raising the upper simultaneously, and feeds with a fly and detent controlled by a shunt-magnet. The main circuit magnet, M, attracts obliquely its armature, rocking the train of wheels

* Paper read before the Society of Arts on March 6, 1889.

Digitized by Google

around the pivot of the first wheel. A lever, L, bent to an elbow which rests on the set screw, V, is also pivoted around the same arbor, and has a vertical arm which carries two attachments; a fork which engages on a pin on the train-frame, and a detent which arrests the fly. The other end of the lever L, is held back by a spring, but can be attracted up by the shunt-magnet S, when the detent is to be released in order to feed.

Product-Regulation.

Before passing away from the feeding mechanism we may return to the question of regulation in general, and in particular to the point that the function of the mechanism of the lamp is to maintain constant one of the two factors of the electric energy, the dynamo being responsible for the other. That part of the electric mechanism which controls the feed is responsible for the steady working of the lamp; and it is this which has to be sensitive to the fall of the current (in constant potential lamps), or to the rise of the potential (in constant current lamps). It is this which must control the feeding mechanism of the lamp. It may be remarked that the striking electromagnet represents the muscle of the lamp, but the feeding electromagnet represents the brains. Now, if the brains of the lamp have to think about and control one factor in the product, why can they not be made to think about and control the product itself? Such a lamp, in which the controlling part is neither an ampere-meter (main circuit) device, nor yet a volt-meter (shunt) device, but a watt-meter device, ought to make the lamp independent of any fluctuations in the supply. Product regulation is clearly in the abstract better than regulation either by the amperes alone or by the volts alone, or by the difference between them; and the mechanism is certainly such as can be constructed. Such a lamp ought to run on any circuit. Let it be remembered that on a constant potential circuit a shunt-magnet can do no more than a spring might do. Neither can a main-circuit magnet in a constant current circuit do more than a spring. A lamp in which both coils are properly combined ought to be capable of working on either kind of circuit. Indeed, there are some existing lamps which will very nearly do so.

Relay Lamps.

It is evident that the brains of the lamp need not necessarily be placed inside the lamp itself; the device of using a sort of *relay*, outside the lamp, to watch the lamp and control its feed, is one that has been frequently suggested (Crompton, Abdank, Gerard, &c.). There is one lamp (Jolin, 2570[83]), in which a shunt relay, itself too weak to move the feed tilting-plate, does the work by opening and closing one of the circuits of a double, differentially-wound, main-circuit electromagnet.

Retarding Mechanisms.

It would be very easy to write a whole chapter on fans, air dash-pots, glycerine dash-pots, and the innumerable devices which have been tried. Two are worthy of mention, namely, Hopkinson's device (153[81]) of altering the rate of feed by raising or lowering mercury in a vessel in which a fan is continuously rotating, and Brockie's suggestion of a liquid brake-wheel containing internal partitions, communicating by small apertures, so that a liquid could flow but slowly from one chamber to another.

Replacement Mechanisms.

These may be classified as follows:—(*a*) In rack-train lamps, a ratchet-wheel on first or second member of train. (*b*) In clutch-lamps with loose clutches, none required. (*c*) In forward-feeding clutch-lamps, some device for loosening the clutch. (*d*) In screw-feed lamps, some device for unclamping the screw gearing.

Focussing Mechanisms.

The various ways of giving to the carbons the desired differential rates of approach are best classified by reference to Fig. 24, which gives four methods of producing a motion of the carbons in the ratio of two to one, and four methods of "commercial focussing," in which the carbons are moved toward one another at equal rates.

Change-over Mechanisms.

These may be classified into those which are purely mechanical (Brush, Thomson-Rice, Bürgin, Crompton-Crabb, &c.), and those which are electrical, the current being switched off from one pair of carbons, and switched on to another (Weston, 1163[82]; Waterhouse, 5185[81]; Trott and Fenton, 6910[87]; Noble, 16376[87], &c.).

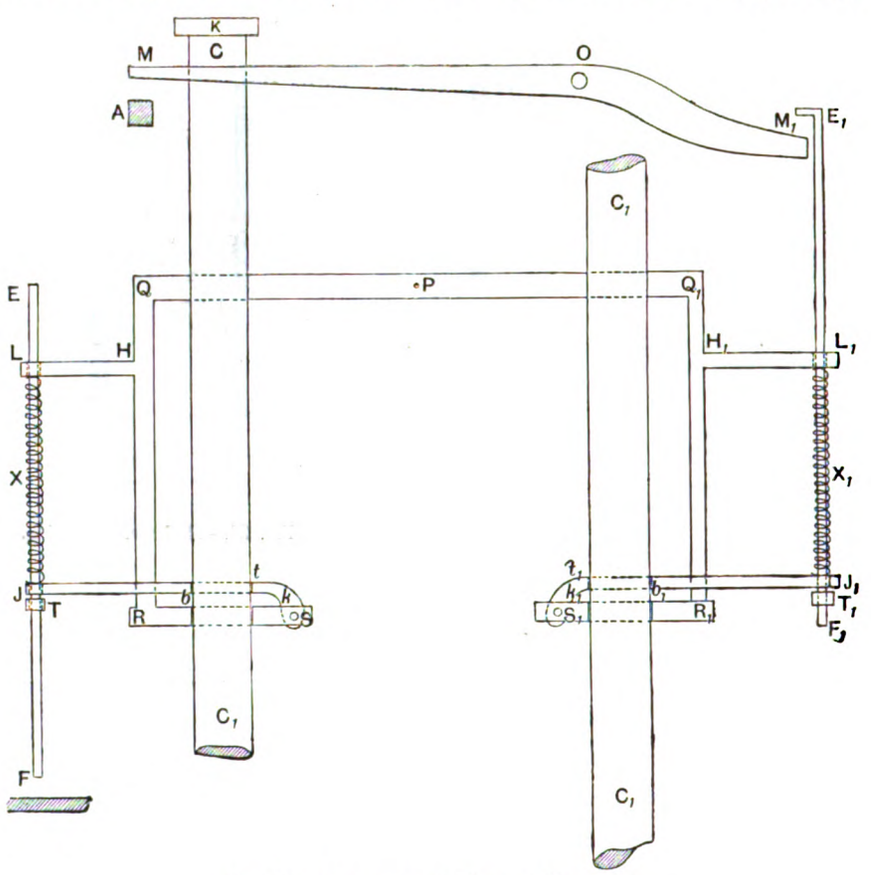

Fig. 26.—Mechanism of Thomson-Rice Lamp.

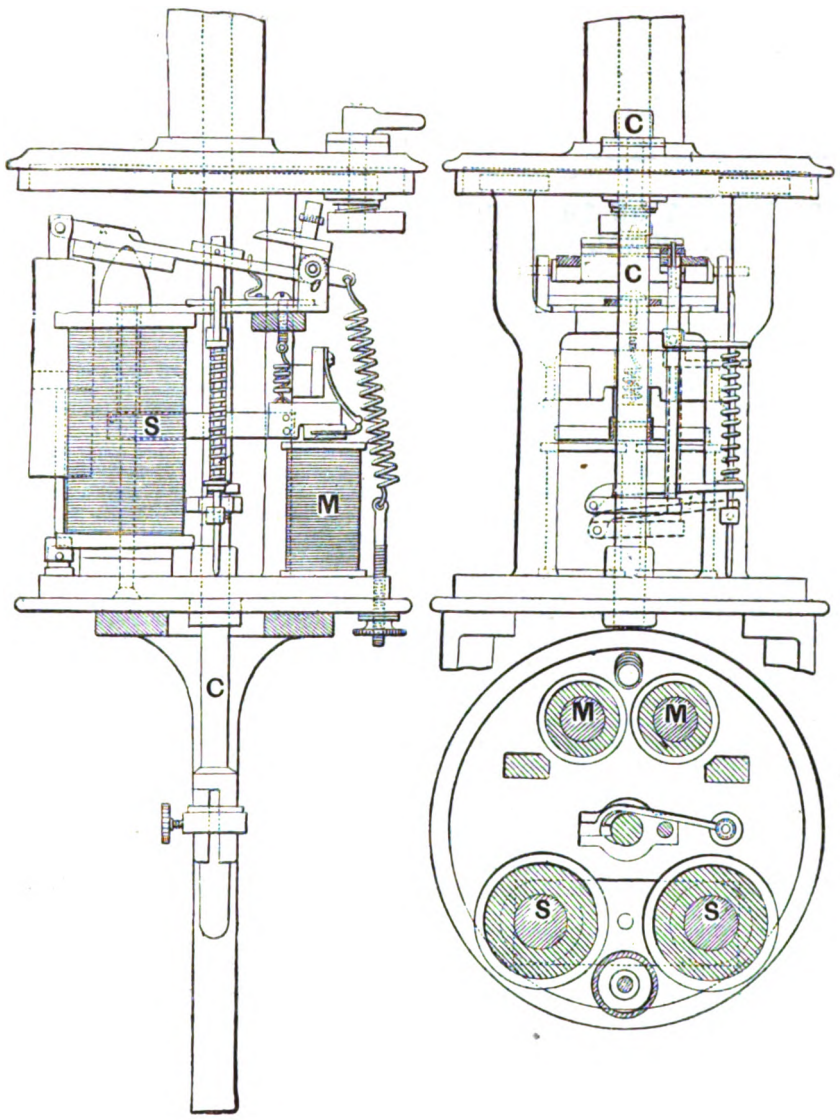
Cut-out Mechanisms.

"Cut-out" mechanisms may also be purely mechanical, but they are more usually electrical, and, in modern forms, enable the lamp to "cut-in" again on the re-establishment of its proper circuit. Cut-outs which enable a shunt-magnet to strike and feed the arc are described by Lever (8443[84] and 11501[84]), and are used in the Thomson-Rice lamp. The latest devices are those of Lauckert (5707[87]) and Phillips and Harrison (7235[87]). In many lamps the cut-out circuit is merely a shunt electromagnet stiffly set, which, on the failure of the lamp, receives the whole current, and pulls over a cut-out switch. Gerard (4792[81]) describes several such devices as well as a cut-out depending on expansion by heat. In the Pilsen lamp (Fig. 21) the cut-out is in an auxiliary main-circuit. Cut-outs depending on the fusion of a wire or of a washer have

Digitized by Google

been proposed by Lontin (20947), Basilevsky (50268), and M'Dill (1887).

The action of change-over and cut-out mechanisms is well illustrated by reference to the Thomson-Rice lamp, of which Fig. 25 illustrates the electrical mechanism and Fig. 26 the mechanical mechanism of the lamp. The terminals are marked +P and −P. The carbon rods, C C and C_1 C_1, are held up by their respective clutches, which are identical with those of the Thomson-Houston lamp (Fig. 14) already described. The clutches, when the lamp is not at work, are themselves held up by the spiral springs, X X, which push down the levers, J and J_1, and push up the arms H L and H_1 L_1, so gripping the rods. The principal electromagnet, S, with its conical poles, has a pierced armature, *a a*, mounted on the end of a strong lever, M N (Fig. 25), which is pivoted at O, the first round the coarse wire on S, most of it going through A and B (which are in contact), and on to −P; but a little of it, after traversing the coarse wire coil, turns back along the fine wire coil and goes by this by-pass route to B and −P. As a result, the armature is strongly attracted, and the lever M N descends, causing the carbon rod to drop. This now opens another route for the current. Starting at +P, some of it will flow through M to the frame, thence through the upper and lower carbons and so to −P. This current will attract the armature A, and break the contact between A and B, breaking the coarse wire circuit through S, leaving the fine wire path still available. Consequently S loses most of its power, and the spring × pulls up the lever M N, so striking the arc. The shunt-circuit (fine-wire) through S is still at work, and continues to operate the feeding, increasing as the resistance of the arc lengthens.



General View of Thomson-Rice Lamp.

M. The cut-out (or cut-in) electromagnet which opens the contacts of the coarse-wire winding on the electromagnet S.

S. The principal electromagnet, wound with fine and coarse wire. The armature of this electromagnet is attached to a lever pivotted at O, and held at its other end by a strong spiral spring. This armature in sinking opens the clutch, and in rising closes it on the carbon-rod, which it raises.

short tail, O N, being pulled down by a powerful spring, X. This lever, thus held up above the poles of the electromagnet, is connected to point P (Fig. 26) of the clutch frame, and holds it up. The adjusting nuts of this frame are so set that when P descends the lower end, F, of the pin, E F, strikes on the base plate and opens the clutch for the left carbon rod, so striking the arc of this pair of rods. When the pencils of this side are consumed, the rod, C C, has descended so far that its projecting head, K, strikes the long lever, M M, the other end of which raises the pin, E F, so bringing the other clutch into action. The electric arrangements, Fig. 25, are as follows:—The magnet, S, is wound with a few turns of thick wire, and with many turns of fine wire. The cut-out (or cut-in) magnet, M, is wound with coarse wire only. The upper carbon rod is connected electrically to the frame of the lamp, whilst the lower carbon, insulated from the frame, is joined by a wire (not shown in the figure) to the negative pole. The current entering at +P passes

The present attempt to furnish a classification of the various mechanisms, electrical and mechanical, of the arc lamp, is probably extremely imperfect, but it may at least claim to supersede the old and ludicrous division of lamps into "monophotal" and "polyphotal." In conclusion, it may be pointed out that there exists a curious sort of family likeness between the several members of the three species of lamps most in use. The rack-train lamps, which may be considered as the prevailing continental type, are for the most part, in their design and construction, essentially clockmakers' lamps; they have a horological aspect. The clutch lamps so universal in America have a sort of sewing-machine look, the working parts being only finished where necessary for actual work, all else being left rough merely or painted over. The clutch-wheel lamps favoured by British inventors have, in contrast to these, a look as though they had been designed and constructed by a trained engineer; they are essentially engineers' lamps.

APPENDIX.—SAMPLE OF FILLING UP OF SCHEDULE.

Schedule of Arc Lamp Mechanism.

NAME OF LAMP.—Thomson-Houston. Single arc.

NATURE OF SUPPLY.—Constant current; amperes 9·8.

RESISTANCES.—*Main circuit coil, 0·09; shunt, 279; cut-out, 0·85 ohms.*

A	*Driving power*.....	Gravity on upper carbon-rod.
B	*Striking*	Main-circuit electromagnet attracts lower end of see-saw, lifts clutch.
b	*ditto adjustment*...	(1.) Special resistance-coil shunting main-circuit coil. (2.) Spring on tail of clutch.
C	*Feeding*	Shunt electromagnet attracts upper end of see-saw, lowering clutch.
c	*ditto adjustment*...	Same as *b*.
D	*Moderating*	Air dash-pot on horizontal tail of see-saw.
E	*Replacement*.....	None required.
F	*Focusing*	None.
f	*ditto adjustment*...	None.
G	*Change-over*.....	None.
H	*Cut-out*.....	Insulated contact on lower end of see-saw, pulled over by shunt-coil, and puts cut-out resistance as shunt from + to − terminal.

THE BOARD OF TRADE INQUIRY ON THE LONDON ELECTRIC LIGHTING PROVISIONAL ORDERS.

In accordance with the notice issued by the President of the Board of Trade, Major Marindin opened an official inquiry on Wednesday, at the Westminster Town Hall, into the various applications for Electric Lighting Provisional Orders for the Metropolitan area.

Mr. Pember, Q.C., Mr. A. K. Loyd, and Mr. J. C. Graham, appeared for the London Electric Supply Corporation; Mr. C. A. Cripps for the Metropolitan Electric Supply Company; Mr. Moulton, Q.C., and Mr. R. S. Wright for the Chelsea Electricity Supply Company; Mr. Muirhead for the St. James's and Pall Mall Electric Light Company; Mr. Roger W. Wallace for the Notting Hill Electric Light Company, for the Kensington and Knightsbridge Electric Lighting Company, and for the Westminster Electric Supply Corporation; Mr. Moulton, Q.C., and Dr. Hunter, M.P., for the Electrical Power Storage Company; Mr. G. Prior Goldney (the City Remembrancer) for the City of London; Mr. T. Percy Gunyon (engineer) and two members of the Council for the London County Council; Mr. C. A. Cripps and Mr. F. M. Jenkins for the Strand District Board of Works; Mr. Hopwood (solicitor) for the Holborn District Board of Works; Mr. E. Bayley (clerk) and Mr. G. W. Thompson (surveyor) for the St. Olave's District Board of Works; Mr. James Spencer for the Greenwich District Board of Works; Mr. J. H. Horton for the Paddington Vestry; Mr. Hitchins for the St. George's (Hanover-square) Vestry; Mr. Wilkins (clerk) and Mr. W. Jenkins (chairman of the Lighting Committee) for the St. James's (Westminster) Vestry; Mr. Webster Murnane (clerk) for the St. Martin's-in-the-Fields Vestry; Mr. T. Eccleston Gibb (clerk) and Prof. Robinson, C.E., for the St. Pancras Vestry; Mr. Cripps and Mr. Greenwell for the Marylebone Vestry; Mr. H. J. Smith (clerk) for the Lambeth Vestry; Mr. Harrison (solicitor) for the Bermondsey Vestry; Mr. E. Moore (solicitor) for the Great Eastern Railway Company; Messrs. Payne, Son and Pollock (solicitors) for the North London Railway Company.

Major MARINDIN said that in the first instance he proposed to consider the application of the London Electric Supply Corporation.

Mr. PEMBER, Q.C., then explained the nature of the order submitted by the London Electric Supply Corporation. With reference to the position of the company, he said it had an authorised capital of £1,250,000, of which about £800,000 was subscribed, the amount paid up being £585,000. The company had expended on works and plant £430,000, which left them in hand about £150,000. That theirs was a substantial undertaking their operations so far showed, and that they had not only got the money, but were expending it wisely and in a far-seeing way, and they had already gained considerable experience in electric lighting. Their system differed from those of other companies because, instead of having a separate generating station in each locality, they proposed to have one large station at Deptford, and to have trunk mains from it which would carry the light to London along the routes of the railway companies, with whom agreements had been entered into. Originally the order was much more comprehensive than it now was, for several districts had been deleted which were included at first. These were St. Mary Abbot's Kensington (part of), St. John's Hampstead, St. Mary's Islington, St. Leonard's Shoreditch, Paddington (part of), St. Luke's, St. George's-in-the-East, Whitechapel District; St. Mary Lambeth, and St. George-the-Martyr, Southwark. The following parishes still remained in the order: St. Martin-in-the-Fields, St. Margaret and St. John (united) Westminster, St. James Westminster, St. George Hanover-square, Chelsea, St. Mary-le-bone, St. Pancras, St. James and St. John (united) Clerkenwell, the Strand District, the St. Giles District, the Holborn District, the City of London and the liberties thereof, and the extra parochial places of Lincoln's Inn, Gray's Inn, and the Inner and Middle Temple, all in the County of Middlesex; the Greenwich District, in the County of Kent; the parishes of St. Mary Rotherhithe, St. Mary Newington, and St. Mary Bermondsey, the District of St. Olave, and the District of St. Saviour and Christchurch, all in the County of Surrey. The company did not ask for any exclusive grant of any district, and did not object to competitors, but were quite ready to see orders granted by the Board of Trade to any other persons within the same area. That being so, there were, he thought, two main questions of principle applicable to their case. First, was it advisable to grant a large area to one company? and secondly, was it advisable to give more than one company powers over the same area? Of course they answered "Yes" to both questions. Competition had obviously been intended by Parliament. He remembered perfectly well that Mr. Stanhope's Committee of 1882 discussed the question of Competition *versus* Regulated Monopoly, and they rejected the principle of monopoly such as had taken place in the case of the Gas Acts, and preferred to leave the matter open, and it was for that reason that they had fixed no maximum price for electricity in the Act of 1882. It would be obvious that if that was the principle upon which Parliament proceeded, the Board of Trade, at all events, should be open to consider the question of unlimited competition in one area. If that was admitted, and if that question was answered in the affirmative by the Board of Trade, it was clear that the first question would also be answered in the affirmative, because, if it was held to be advisable to give more than one company powers over the same area, there would be no harm whatever in giving to the company who applied for it as large an area as it thought fit to cover. The possession of a large area over which they could expatiate, and in which they could employ profitably their capital, would be a great encouragement to the investment and consequent cheapening of supply. There was, at all events, nothing in the Electric Lighting Acts of 1882 and 1888 to prevent the Board of Trade giving effect to this view: that Board had a perfectly free hand, and he hoped they would use it. After describing the company's works at Deptford, the learned counsel invited Major Marindin to pay them a visit before the termination of the inquiry. The works were large and compact, and thoroughly well considered, and they were a largely-devised attempt on the part of the company, who hoped to be one of the largest purveyors in London, to do something analogous to what had been done by the gas companies—when they moved from London to Beckton—for the public of London. They hoped that before long Deptford would become an electrical Beckton. The intended plant of the company would consist of four double engines and dynamos of 10,000 horse-power each, and there would be two smaller engines, each of 1,500 horse-power, and these two smaller ones would be ready for use a month hence. The first of the large ones would be ready by November next, and the second one in December, probably. A supply of 230,000 lights could be given constantly by these engines. If necessary they could be duplicated very speedily, and it was not too much to say, in fact, that the plant could be multiplied yet further on the existing premises of the company, and if called upon to do so the company could give a daily supply of 1,000,000 lights. To carry out their scheme of having trunk mains to London they had arranged with the London, Brighton and South Coast Railway Company, the London, Chatham and Dover Company, the Metropolitan Railway Company, and the South-Eastern Railway Company—his company's works were situated near the South-Eastern Railway at Deptford—for the mains to be carried along their lines and bridges, which would enable them to avoid breaking up suburban streets. The current when it was thus brought to London would be distributed to various stations, where it would be connected from the high pressure at which it was brought into low pressure for the private houses; and would then be distributed by ordinary supply wires to the private customers. The advantage of this over other systems was the removal of different generating stations out of town to one place in the suburbs. That would be a great advantage to all parishes concerned. It would remove the nuisance of the noise of moving machinery. There would be no smoke, or carriage of coal through the streets, and the absence of the manufactory itself must obviously be a great boon to everybody, for it was conceded that the nuisance from existing stations in the metropolis—at Paddington, Jermyn-street, and the Grosvenor Gallery—had been very great. It had only been by assuring people that it was intended to apply for this Provisional Order and to move to Deptford that his company had avoided lawsuits. With regard to the coal cartage, if a parish were taken having 200,000 inhabitants, and they were allowed 200,000 electric lights, one light per head, then for the production of those lights 408 tons of coal per day would be required. That was on the assumption that condensing engines would not be used in populous places. To carry these 408 tons of coal each day 200 cartloads would be necessary, and there would be other carts required for the removal of ashes and waste and for the cartage of oil, and that cartage would be a serious addition to the heavy traffic of a crowded parish. It would cause serious obstruction. Sufficient coal storage would not, moreover, be practicable in separate parishes, and a snowstorm or a fog might be the cause of a parish being left in temporary darkness through the traffic for the supply of coal being stopped. The cheaper land to be had in the suburbs, and the unity of management resulting from concentration of works, would further add to the economic gain to be obtained. The company's works were also on a river frontage, and the company could bring their own coal direct in their own steamers to their own wharf, and this would reduce the cost of coal from 20s. or 25s. to 12s. or 15s. a ton. All these things would tend to the benefit of the consumer. And, finally, they had abundant water at their command there, and could use condensing engines, which would further tend to cheapness of production. The relative advantages of this company's system would be further explained by their engineer, Mr. Ferranti. The distributing mains would be comparatively small one capable of conveying power for 100,000 lights occupying only a space of 2¼in. diameter. This smallness of the tubes reduced the breaking up of streets to a minimum, and the company were perfectly ready to co-operate with any other company who might be serving the same district on that point, which would secure joint opening of the streets. The learned counsel then touched upon the applications for other orders, and the attitude of their promoters towards his clients. Besides the orders, two licenses were applied for—one by the Chelsea Electricity Supply Company and

Digitized by Google

one by the House-to-House Electric Light Supply Company; and he invited Major Marindin to consider these matters solely as they affected the London Electric Supply Corporation. The London Electric Supply Corporation only opposed the other applications conditionally; it had no objection to them. The other methods did not affect them except on the consideration that only one company should be allowed on one area, and, if that was to be the rule laid down by the Board of Trade, then his company would oppose all those applications, contending that their own system was the best, and asking that it should be the one authorised. If competition was admitted, they were so confident of the superiority of their system that they would have no fear of the presence of any number of competitors.

He would now select typical examples of the objections lodged by the various parties, to show the general scope of the opposition. First, it was urged that the period settled by Parliament last year of forty-two years as the term for the acquisition of the undertakings by local authorities should be reduced to twenty-one years, which was the period fixed by the Act of 1882. His reply to this was that Parliament and everybody concerned had felt that twenty-one years was too short, and that that limitation had crippled enterprise. The Earl of Camperdown's Select Committee in 1886 took overwhelming evidence to that effect, and the Board of Trade would not be likely to go back to that limitation. A local authority might be anxious to get hold of a profitable undertaking on easy terms, but Parliament had held the scales between such local authorities and the undertakers, and had determined not to allow it. That was the meaning of the 1888 legislation as against the 1882 legislation. The St. James's, Westminster, Vestry proposed the insertion of a clause forbidding one company acquiring or associating itself with another undertaking in the same district, which was more than they were entitled to ask, there being already legislative provision upon the point. It was an open question at present whether undertakers under a Provisional Order should or should not be allowed to transfer their undertaking. He saw nothing in the Acts of 1882 and 1888 giving express power to do so. It was at any rate a matter to be settled by the supreme authority, and not by a local authority, and the Board of Trade was abundantly safeguarded against any improper transfer. Then it was also suggested that the company should provide in some way a pecuniary deposit, he supposed as a guarantee that they would carry out the work. This was a question of degree. If it were a question of depositing some not very large amount, say, £10,000 or £20,000, in respect of the whole order, the company might not raise any great objection; but to give more than that—to give a sum of £500,000 as had been suggested, for every parish—would be a very serious matter, and a course that would seriously hamper the finances of any company, however sound its position might be. He did not think it would be recommended by the Board of Trade. It would be against public policy to lock up a sum of money like that, which might be well employed in the furtherance of the order itself. Next, there was a proposal for a provision prohibiting the connection of a circuit with the earth, which was not a question to be decided by local authorities, but, once for all, by the Board of Trade, acting upon the advice of its scientific advisers. Then it was suggested that the local authority should have the approving of the distribution boxes, as to their size and pattern. His objection to that was that it would give the local authority undue control over matters upon which they were not very well qualified to form a judgment. These boxes would be comparatively small.

A more important matter was that of overhead wires, and the proposal was made to insert words to the effect that an order was to confer no powers to erect overhead wires, to which he should not object if that were all, but he should strenuously object to the words going further. At the present moment he believed that the company had, in common with a good many telegraph and telephone companies, a common-law right in this matter, and could put up overhead wires, having got the consent of owners and occupiers, provided the wires were carried at a sufficient height to take them from house to house, and such wires existed in great numbers over London streets. The Telephone Company, he believed, did all its business in that way, and he should strongly resist any words being inserted which would have the effect of controlling or limiting their present legal rights in that respect. They were, however, perfectly ready to have words inserted that the order should confer no such power. The following agreed words had been put into several Provisional Orders already:—

"*Nothing in this order shall authorise the undertakers to place electric light wires above ground, along, or over, or across any street, without the express consent of the local authority.*"

To that extent his company had no objection to the proposed amendment, but beyond that they would not go. There were some other objections which he would prefer to leave to the determination of the Board of Trade arbitrator. The Company sought to be exempted from the provisions of the Building Act of 1855. The City of London took the view that they were in an exceptional position, having powers under their own Acts of Parliament, which authorised them to grant the requisite facilities for electric light undertakings, and they declined to assent to any powers being given by Provisional Orders which would affect the area of the City of London. They had further elaborated a plan of their own for the lighting of the City by public tender. This plan the company considered was open to very grave objection, as they did not think that any electric lighting company which valued its position would accept the terms offered in the form of tender proposed by the City. They contended that the City was not in the sense claimed outside the Electric Lighting Acts, which defined local authorities, and among the local authorities there described he found the City of London and the liberties thereof defined as one, and he therefore failed to see that the City was exempted from the purview of the Acts. It would be for the Board of Trade to decide. He maintained that the dissent of a local authority could not be a veto. The Board of Trade had an undoubted right to grant the order now asked for, or any other order, against the wishes of a local authority.

The EARL OF CRAWFORD AND BALCARRES, Chairman of the London Electric Supply Corporation, examined by Mr. LOYD, said that the corporation had been formed to take over Sir Coutts Lindsay and Company (Limited), which was started in 1885. When the directors found that they had reached a point when the undertaking could not be carried on, they resolved to make it a larger affair, and the present company resulted, the directors remaining the same, and had the experience of five years. The directors, soon after they commenced, concluded that it would be very advantageous if they could get a position away from a populous area to supply the electricity from a distance. There had been eleven threatened injunctions altogether, some of which had been "squared," others fought, and others again they were fighting. The assurance that they were looking out for another place at a distance had induced others to stay their hands. He believed that both the Paddington and the Jermyn-street installations had been threatened in the same manner. They had capital to supply as much light as was likely to be required at first; they did not contemplate having to supply the whole area at first. The progress of the adoption of the light must be gradual, and the use of electricity as a motive power he believed would eventually throw lighting into the shade. The Deptford works had been arranged with a view to gradual development, and in a way that additions could be conveniently made. One of the smaller engines had been running last week under steam of 1,500 horse-power. They were also putting up two machines, engine and dynamo combined, of 5,000 horse-power. A second engine could be added to the same dynamo, giving a maximum output of 10,000 horse-power. The first one they hoped to have ready next August. With that amount of horse-power available each machine would give a current for 100,000 ten candle-power lamps. According to their experience of the smaller class of dynamos each would probably give a current for 120,000 lamps, and that would give a total of 240,000 lights. The distance it was proposed to carry the current under the present order was about seven miles, from Deptford to Chelsea, and there would be no difficulty whatever in transmitting the current with safety to life and property for that distance.

As to multiplicity of undertakings in one area, he was of opinion that, although it was of advantage to a company to have no competitor in the same area, it would be a distinct advantage to the public to have more than one. There would be less disturbance to the streets in laying the mains proposed than there was in laying the gas mains, and there was no reason why two mains should not be placed in close proximity. His company were entirely opposed to monopoly, and considered it to be contrary to the spirit of Parliament. They asked for no exclusive powers. If only one company was allowed in one area, then they considered that theirs would be the best system to be adopted.

Cross-examined by Mr. MOULTON: His company was bound to no system, but took the one they considered to be best; but it did not follow that any other company could adopt any method which they might take. Some were protected by patents. They proposed to adopt the transformer system. He had not gone into the details of the cost of thoroughly lighting all the streets in an area, but he would put it at 12s. 6d. a yard—1,100 miles at 12s. 6d. a yard. To state the whole cost he would require to be told how many lamps he had to supply, and, to guard against accident, a duplicate plant. The current would be carried into the houses at a pressure of 2,000 volts, but would be transformed down to 100 volts.

The witness was further cross-examined as to the means of working the system, both on the works at Deptford, at the distributing stations, and in the houses supplied.

Mr. GOLDNEY, the City Remembrancer, representing the Corporation, who also opposed, asked some questions, and the witness said that it was impossible to say how much of the company's capital, now raised to £1,250,000, would be necessary to work the City lighting. The company could not make such a calculation until they knew what they had to do, and they had not allocated any amount to any area. The company knew that if they needed more money they would be able to get it. The abandonment of applications by the company as regarded Islington, part of St. Margaret's Westminster, Whitechapel, and other places had nothing to do with capital. Paddington, Hampstead, Shoreditch, and other places were taken off in order that the Board of Trade should not consider the company was asking for too large an order.

The inquiry was adjourned until the following day.

THURSDAY.

On the resumption of the inquiry on Thursday Lord CRAWFORD was further cross-examined by Mr. GOLDNEY, in reply to whom he stated that he considered that the City of London should come under the Provisional Order, inasmuch as it was included in the schedule to the Acts. The London Supply Company proposed to enter the City at Cannon-street and at Ludgate Hill, and they hoped eventually to enter at a point further east. The area of the City was important to the company, because the greater part of the lighting there would be done in the day time. They were prepared to supply either arc or incandescent lighting, according to what the City was prepared to pay. The specification issued by the Commissioners of Sewers for tenders showed that in the three districts there were respectively 388, 526 and 633 gas burners—altogether 1,500 burners. Five hundred arc lights would supplant those gas burners. He had not worked out a complete scheme for the City because he did not wish to waste time in making a hypothetical scheme which the order might at once upset. His company were prepared to supply the City on as good terms as they would give to any other consumers; but he could not tell what tenders the company might make. He certainly would not give a supply on the terms proposed in the Commissioners' specification, and considered them unfair to everybody. He apprehended that the

Digitized by Google

Commissioners were not empowered to say whether or not a company should supply the City, but that that was a matter for the Board of Trade.

In reply to Mr. CRIPPS, who represented the Metropolitan Electric Supply Company, Lord CRAWFORD said it was his conviction that it was more economical to buy electric light from one large station than from several small stations, as under the system of the Metropolitan Company. With regard to the question of cheapness of coal through the convenience of site, he was aware that cheaper coal than navigation coal could be used, with modern appliances, without causing any smoke nuisance, but not without the nuisance of noise. His company had tried the modern appliances, but they had failed to work satisfactorily because they could not get rid of the noise. He was aware that there was a station working in Whitehall, but it was on private ground, and the only neighbour was the Hotel Metropole, and as engines were also at work there, no complaint as to noise could be made on either side. The Whitehall Station was a very limited one, and the London Company could not work in the same way.

Replying to Mr. SHIRESS WILL, representing the House-to-House Supply Company, Lord CRAWFORD declined to state how much of the half million that his company had expended on works had been expended at Deptford, not considering himself called upon to produce his balance-sheet. Referring to the plant at Deptford, he explained that they had unit machines in the same way as that proposed by the House-to-House Company, but their unit was larger than others, and they kept a spare unit in reserve in case of a breakdown.

Mr. S. WILL, Q.C., M.P., appearing on behalf of the House-to-House Company, said he proposed to put a few questions as to the policy of one large company being in opposition to several small ones.

A technical objection was raised on the ground that the company was not before the inquiry, but eventually it was allowed.

Lord CRAWFORD, in reply, said his corporation proposed to take a large area, and to commence over the whole ground at once. He could not give an estimate as to what the whole cost of the complete work would be, and until he knew the number of miles to be opened at first he could not tell what the initial cost would be of starting at all these places together. It was proposed to open 18 centres. A mile of mains from each of these centres would cost altogether, he estimated £30,000, and an additional 12s. 6d. a yard for excavation.

In reply to the representative of the Vestry of St. James, Westminster, Lord CRAWFORD said he was of opinion that the application of electricity as a means of motive power would become in a short time quite as much in request as its application to lighting, and his Corporation hoped to be able to apply electricity to motive power. They had made no provision for a day's storage, and in view of a strike of all the stokers it would have the effect of putting London in darkness; but they had got a special Act, and the stokers would also come under the Gas Act. The *contretemps* was possible to the Corporation, but it was also possible to any other company. He bowed to the authority of the London County Council. He believed in friendly competition among the electric light companies.

Lord Crawford was also cross-examined by representatives of other local authorities.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 23rd*, 1889.

An important decision was rendered this week by Judge Coxe, of the United States Circuit Court for the Southern District of New York, which bears directly upon the use of the accumulator in this country. The Electrical Accumulator Company, owning the Faure, Swan, and other patents, had sued the Julien Electric Company for infringement of the same. The judge, after a very long and exhaustive review of the case, has decided that the Electrical Accumulator Company is not entitled to the broad construction of the claim of Faure of the application of an active material to the plate of a storage battery; but on filing a disclaimer, limiting the first claim of the Faure patent to an electrode of a secondary battery to which the active layer is applied in the form of a *paste*, *paint*, or *cement*, it will be entitled to a decree for and injunction, and an accounting upon the same as thus limited, but without costs. Regarding the patent of Swan, which related to the perforations in the electrode of the secondary battery, the judge held the same to be invalid, due to prior work, which was shown during the trial. The application of the active material other than in the form above-mentioned is therefore held to be no infringement of the Faure patent, and as the Julien Company now claim that they do not apply the active material in any such form, they would appear not to infringe the patent at all. We shall probably learn more about this, especially as it is claimed that the man most benefited by the decision is Mr. C. F. Brush, who holds important patents in this field.

Some very interesting figures have just been compiled by the *Progressive Age* of this city, a journal devoted comprehensively to gas and other lighting interests, showing the number of gas companies in this country operating electric light plants. A list of the same kind was published by the same paper last October, from which it appeared that there were then 150 gas companies, operating 12,834 arc light, of 13 different systems. The present list shows a remarkable gain, there being no fewer than 266 companies, operating a total of 21,313 arc lights, and 55,890 incandescents, representing no fewer than 21 different systems. These figures are approximate, but if anything should be larger, some of the companies having failed to go into details. The result shown is a remarkable exemplification of the change of front on the part of the gas companies, a change that is undoubtedly due in no small measure to the work of the paper in question, which has been incessant and unremitting in its advocacy of a combination of the two interests, gas and electricity. Going into the details of the figures, it appears that the gas companies are operating 11,084 arcs of the Thomson-Houston system, and 8,826 incandescents. The Brush Company comes next with 3,964 arcs, the American next with 1,813. Of incandescents there are also 27,710 Westinghouse, and 10,256 Edison.

This matter, as to the combination of gas and electricity, is touched on in a very interesting way in a book which has just been published by Mr. A. R. Foote, of Cincinnati, entitled "The Economic Value of Electric Light and Power." Before I go on to mention the leading subject of this timely work, I may note that several well-known gasmen are quoted as to the desirability of operating gas and electric light plants together. It is not a little amusing to find among these authorities General A. Hickenlooper, the president of the Cincinnati Gas Light and Coke Company. Only a few years ago—three or four at the most—General Hickenlooper was fighting the electric light tooth and nail, and tongue too. He was not merely satisfied with opposing it locally, but took the trouble to collate a large number of alleged electric light accidents and failures, and put them all together in the Cincinnati daily papers, which were then scattered broadcast all over the country. More than this, the General took occasion to reprint this literary masterpiece in pamphlet form and to constitute himself a tract society for its free and liberal distribution. But the times have changed and Hickenlooper with them, and now we find him saying, "I think the time has come when the electric and gas interests should be united to perform the service of supplying cities and towns with light, heat and power." Another authority quoted is Mr. T. Turner, president of the Gas Light Association, who deprecates as a mistaken policy that so often pursued by gas companies and engineers, of fighting the electric light.

But the main point brought forward by Mr. Foote is the question of whether it is well for cities to own and operate their own electric light plant. This is a vital topic at the present time, because on every hand we see large numbers of cities investing the proceeds of local taxation in the purchase of electric plants, some large and some small, and all on the plea of obtaining economy and effecting a saving to the city. Mr. Foote, who read a very forcible Paper against this tendency at the recent meeting of the National Electric Light Association, now prefaces his book with a section of some fifty pages, devoted to a discussion of the same topic. Mr. Foote there takes occasion to point out the mistakes made and the erroneous arguments used in pushing this policy, and advocates as an alternative that each city should grant an exclusive franchise, under strict and rigid conditions, to one local company for the supply of electric light and power. On its side the company shall guarantee putting in a plant capable of performing all the service required, and in return it shall hold its franchise for a given number of years, so that this investment, at least during that period, will be permanent and free from disturbance, whether by competition or by the sudden withdrawal of city contracts. Mr. Foote believes that in return for such a franchise as this a great many cities would obtain their own street lighting on very low terms, much lower, in fact,

Digitized by Google

than if it went into the business itself. I have no doubt that Mr. Foote's little book will find a great many readers, and it seems likely to have a good deal of influence at this time.

News comes from Boston of the great interest being taken there in the Thomson Electric Welding Company. The stock is in brisk demand, and I think I have already mentioned that very good results have been obtained with the latest forms of apparatus. Prof. Elihu Thomson has lately built a new alternating-current dynamo, the object of which is to obtain the magnetic field as rapidly as possible. This not only saves time, but is very desirable from the fact that it is often necessary to have a rapid building up of the field for good work. In this new machine, so rapidly do the fields build, that in welding a 2in. piece, from the time that the rheostat is set till the fields have become thoroughly saturated is but 2sec. The machine is wound for 300 volts potential, and with a current capacity for welding 2½in. solid iron will give 125 amperes at that voltage. A very interesting series of experiments is now being made at the factory of the company at Lynn, in order, if possible, to arrive at some law governing the amount of energy required to weld the different sizes of the same material. It appears that there is quite an extraordinary variation in the time and the quantity required. It is found, for example, that in welding ½in. wrought iron about 10 horse-power is required for some 8 or 10 seconds, whereas in welding 1in. iron 20 horse-power is required for 40sec.; but even these figures do not appear to bear any relation to any others. As is already known, the energy represented is mainly accounted for by the volume of current flowing. With 1in. iron, for instance, there will be some seven or eight thousand amperes at considerably less than half a volt E.M.F. This is certainly an interesting field of investigation, and at the hands of Prof. Thomson will be sure to bring out some interesting effects.

Speaking of the activity in Thomson welding stock reminds me of the fact that latterly there has been no less activity in the stock of the Thomson-Houston Electric Company, which, as everybody knows, devoted itself to light and power. In the hands of Mr. C. A. Coffin this company has attained a marvellous development. In 1883 it had 22 sub-companies, operating about 1,500 arc lamps. To-day it has nearly 450 operating over 50,000 lamps, while 175 companies are doing an incandescent business and running about 100,000 lamps. In the electric railway business the company has already made great strides, and it has now some 30 or 40 roads in operation; in fact, it is reported that the company did a total business of about $4,000,000 in 1888, at a profit of $1,200,000, and that it has a business in sight for 1889 of not less than $7,000,000. It can readily be understood that on such figures as these the stock of the company is held at rapidly advancing figures. According to statements from Boston, the manner in which stockholders in the company enjoy handsome profits, even when no dividends are paid, is an ingenious and interesting one. The method consists in taking the shares of various sub-companies organised to use the Thomson-Houston system and placing them in a pool. The certificates in this pool are then offered to the shareholders at a certain figure. This figure not only allows the parent company a handsome profit, but in view of the price that the certificates fetch in the open market, and the return of them from the interest paid by the various local companies, there is a handsome dividend to the shareholders as well. Thus, for instance, the shares in series C of the pool certificates offered to stockholders for $10 were soon sold at $18, and probably could not be obtained now for less than $20. Hence the right to take these pool certificates is of considerable value, and the stockholders stand to make an excellent dividend. It is evidently a great deal better policy thus to mass these securities of the local companies and place them in a pool which sells at a good figure than to dump them at haphazard on the open market, that does not have a fair appreciation of their value, and where they might often go begging. There is no question as to the shrewdness of the business policy that has governed the Thomson-Houston management, and the company seems to have been fortunate not only on this respect, but in the technical skill that it has commanded from the start.

While we thus find the affairs of one of the youngest of the great electric companies in excellent condition, it is to be noted that the old Western Union is still pursuing the even tenor of its way, and paying substantial dividends. The returns from this vast property are now about as steady and as fair as those of any other large property entrusted to the mercies of the stock market, and there seems to be no good reason why the company should not go on paying higher and better dividends for some time to come. At the present rate of 6 per cent. per annum the company is able to add to its surplus $2,000,000 or $3,000,000 a year, and there are a great many stockholders who would like to see the rate of dividend increased. It is a little bit singular, by the way, that while the newer electrical companies on a large scale find it to their advantage to secure all the first-class technical talent that they can, the Western Union of late seems to have convinced itself that it can get along without any such talent at all. Not long ago the company relinquished the services of Mr. G. A. Hamilton, who has been with it so long. How the company can allow so good a man to leave it is what very few of us can understand, but there is no doubt that Mr. Hamilton will be warmly welcomed in the ranks of the Western Electric Company, which he joins. As I need hardly remind you, the Western Electric Company does all the heavy manufacturing for the telephone business of this country. It also has a good electric light system, and goes in largely for miscellaneous work. It has a huge factory in Chicago, and has just finished one in this city; hence it is a good field for an electrical expert such as Mr. Hamilton, but it seems to an outsider that there should have been plenty of work for that gentleman amid his old associations.

There is considerable activity at the present time in the storage battery field here, and large numbers of cells are being sold, not only for lighting, but for traction. An interesting report comes this week from Detroit of tests made there with the Detroit storage battery of the Woodward Electrical Company. It appears that a car equipped with this battery and furnished with a motor, &c., made by Mr. F. B. Rae, ran very successfully on March 13 on the Highland Park Railroad. With 84 cells, rated at 300 amperes, the cars made eleven round trips, carrying passengers in the regular way, making a speed of from ten to eleven miles an hour, and running 80 miles. This was done on one charge of battery, and four 16 candle-power lights were run from the cells after dark; and in addition to that next day it was found that the E.M.F. of the cells was still up to two volts, and that there was current enough for another trip or two. These strike one as pretty good results, and if they can only be maintained the Detroit Battery Company will certainly be heard from again. It will be remembered that this battery is made by taking a mixture of salt and lead, which is cut into plates of the desired thickness, out of which the salt is dissolved, leaving the plate full of holes of irregular shape throughout. In these pores a paste of oxide of lead is put in the regular way, after which the plates are formed, and are then ready for use. According to tests made by the John Hopkins University of this battery lately, under Drs. Louis Duncan and G. A. Liebig, the efficiency of the battery reached as high as 75 to 80 per cent.

There appears to be a general feeling of real pleasure in electrical circles at the smash up of the French copper syndicate. The corner of the Copper Market has had a seriously detrimental effect on electrical industries here for some time, not only crippling old concerns but causing new ones to hold back. I could mention several instances in which the high prices of copper has interfered with extensive electric light operations, and now that the market has gone back to something like a normal condition we shall undoubtedly see greater activity all round. It may perhaps take some time to have trade falling into its regular channel, and to get prices on the right basis, but when we find copper here down again to 11 or 12 cents a pound we know pretty well that the days of the copper corner are ended. It is publicly stated that the price of laying down good copper in this city from the Tamarack mines in 1887 was only 5¾ cents a pound, and 7 cents from the Calumet and Hecla, so that those companies must have been doing pretty well with rates up to 14 and 15 cents a pound.

CORRESPONDENCE.

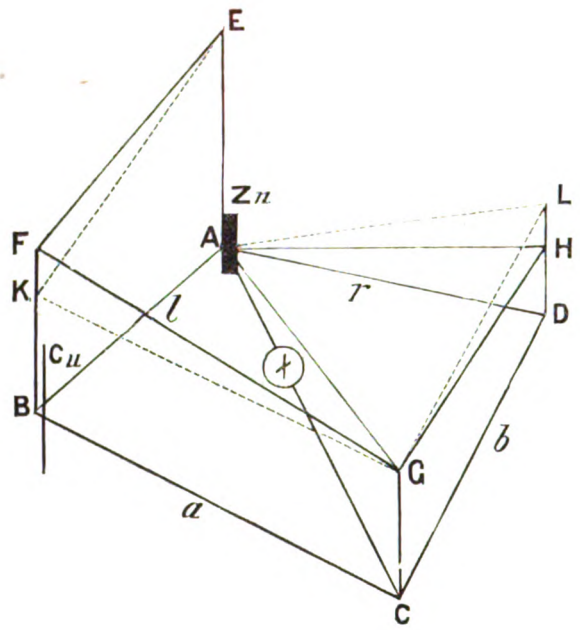
MANCE'S BATTERY RESISTANCE TEST.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following simple proof of Mance's method of finding battery resistances may be of interest :—

The figure represents a perspective view of the bridge and of the currents in the various branches. A B is the arm containing the battery whose resistance l is to be measured. Let the resistances in the other arms be represented by a, b, and r. A E, B F, C G, and D H are drawn perpendicular to the plane A B C D, and their lengths represent the potentials of the points A, B, C and D, before the connection between B and D is made. The potential A E is that of the surface of the liquid in contact with the zinc plate, the potential of the zinc plate itself being considered zero.

When the connection between B and D is made the potential of B will fall and that of D will rise ; but if the balance is properly adjusted the potential of C will not be affected since the current in the galvanometer is unaltered.



The currents in the arms of the bridge are now represented by the dotted lines E K, K G, G L, L A. The current in b will be decreased. If the connection between B and D has less than a certain resistance $\left(\frac{a\,r}{g}\right)$ this current will be reversed.

Now let C_a, C_b, C_l, C_r be the currents in the branches before the connection B D is made, and let C'_a, C'_b, C'_l, C'_r be the currents after B D is closed, and let C_g be the current in the galvanometer, then

$$\begin{aligned} C_g &= C_a - C_b, \\ &= C'_a \pm C'_b, \\ &= C_l - C_r, \\ &= C'_l - C'_r ; \end{aligned}$$

therefore $$C_a - C'_a = C_b \pm C'_b,$$

and $$C'_l - C_l = C'_r - C_r ;$$

but $$C_a - C'_a = \frac{F\,K}{a},$$

$$C_b \pm C'_b = \frac{L\,H}{b},$$

$$C'_l - C_l = \frac{F\,K}{l},$$

$$C'_r - C_r = \frac{L\,H}{r} ;$$

therefore $$\frac{F\,K}{a} = \frac{L\,H}{b},$$

and $$\frac{F\,K}{l} = \frac{L\,H}{r},$$

dividing one equation by the other we get $\frac{l}{a} = \frac{r}{b}$, or $l : a :: r : b$.

It will be observed that the proof is independent of the assumption that the potentials of B and D are equalised on connecting them together, which shows that the insertion of a resistance between them is as efficacious as short-circuiting them—a result found to be the case experimentally. The resistance between B and D may vary between 0 and ∞ without altering the value of C_g if $l : a :: r : b$. The less the resistance, however, the better the test.—Yours, &c.,

R. L. HIPPISLEY, Capt. R.E.

Chatham, April 2, 1889.

THE USE OF FEEDERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your notes of last week on Prof. Forbes' Paper on "Central Station Lighting," you say that you are not aware of "a single instance of the use of feeders in this country at the present time." In our system of underground mains in Liverpool, which has been in daily operation since December, 1888, we have made extensive use of feeders. Our mains now extend over an area nearly one mile long and half a mile wide, and more than four thousand lamps are connected to our wires, the current being supplied from three central stations. The whole of our supply is measured and charged by meter.

We venture to think Prof. Forbes deserves the thanks of the electric lighting community, as it is obvious he does a more valuable work in collecting and bringing to our notice experience from abroad than he could do by ascertaining and publishing what has been done in his own country.—Yours, &c.,

Liverpool, April 2, 1889. HOLMES AND VAUDREY.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

March 2, 1889.

3,687. W. J. S. BARBER-STARKEY and F. G. HOWARD. London. Improvements in apparatus for establishing electrical connection, and also for breaking the same at will at any desired distance from the operator.

3,697. J. A. KINGDON. London. Improvements in the construction and application of transformers for the distribution of electricity for lighting and other purposes.

3,708. J. KENT. London. An improved method for joining electric conductors.

3,730. H. M. GOODMAN. London. Improvements in apparatus for use with cables when it is desired to establish electrical communication between a moored lightship or other vessel and some place at a distance therefrom, whether on shore or otherwise.

March 4, 1889.

3,761. H. C. L. HOLDEN. Woolwich. Improvements in electric tubes and fuses for firing ordnance and exploding torpedoes and mines and for like purposes.

March 5, 1889.

3,808. J. C. RICKETSON. London. Improvements in electric signals for engine shafts.

3,813. A. R. BENNETT. Glasgow. Improvements in telephonic switching apparatus.

3,835. E. BÖHM. Shepherd's Bush. A new or improved incandescent electric lamp.

3,836. L. HANSON. Halifax. Improvements in electric arc lamps.

3,841. W. P. THOMPSON. Liverpool. Improvements in or relating to regulators for systems of electrical distribution (The Westinghouse Electric Co., United States).

3,870. H. H. LAKE. London. Improvements in electric-motors and dynamo electric machines (O. Lugo, United States).

3,881. J. W. BALET. London. Improvements in the method of and apparatus for regulating electric currents.

March 6, 1889.

3,889. F. G. HOWARD and A. J. OBERMAYER, jun. London. Apparatus for opening or closing the shutter of a photographic camera by means of electricity.

Digitized by Google

3,907. T. Parker and E. S. G. Rees. Manchester. Improvements in electrical switches.
3,940. G. A. Schoth. London. Improvements in galvanic batteries.
3,954. P. M. Justice. London. Improvements in electric signalling systems and apparatus for railways (T. P. Worrall, United States).
3,971. J. J. Rathbone. London. Improved compound or admixture of ingredients suitable for producing electric energy.

March 7, 1889.

3,987. A. Wright and G. J. Philpott. Brighton. Improvements in measuring and regulating instruments.
3,990. W. P. Thompson. Liverpool. Improvements in dynamo-electric machines, whether generators or motors (La Compagnie Continentale Edison, France).
4,004. R. H. Courtenay. London. Improvements in electric apparatus which may be combined with mechanical apparatus for the transmission of sound. The combined apparatus may also be applied to other useful purposes.
4,029. G. Wilkinson. London. Improvements in the distribution of electric energy.

March 8, 1889.

4,029. W. F. Smith and J. Sinclair. London. Improvements relating to electric lamps.
4,125. W. O. Rooper. London. Improvements in holders for incandescent electric lamps.

March 9, 1889.

4,171. W. L. Wise. London. Improvements in accumulators or secondary batteries (F. C. Glazer, Germany).
4,192. Siemens Brothers and Co., Limited. London. A new or improved regulator for transformed electric currents (A. M. Taylor, India).

March 11, 1889.

4,208. H. T. Harris and A. Gay. London. The automatic regulation of E.M.F. or current in dynamo machines.
4,235. J. Conte. London. Improvements in coin-freed dynamo-metric apparatus.
4,250. J. E. Spagnoletti and J. Crookes. London. Improvements in apparatus for attaching and superseding electric lamps.

March 12, 1889.

4,287. J. W. King. London. Improvements in instruments for measuring electric currents.
4,296. J. Kynoch. London. Improvements in galvanic batteries.
4,336. T. Spencer. London. Improvements in electrical switches (H. T. Paiste, United States).

March 13, 1889.

4,371. G. Hookham. Birmingham. Improvements in electricity meters, parts of such improvements being applicable to electrical clocks and other electrical instruments.
4,407. H. E. M. D. C. Upton. London. Improved method of and means for code signalling with electric telegraphs.

March 14, 1889.

4,448. F. E. Elmore. Cockermouth. Improvements in or pertaining to incandescent electric lamps.

March 15, 1889.

4,518. G. Shackleton. Bradford. Improvements in apparatus for electrically regulating the "drag" on the fibres during the operation of spinning and twisting.
4,519. W. Hartnell. London. Improvements in electric cranes and hoists.
4,530. H. S. Price and H. J. Dowsing. London. Improvements in coin-freed apparatus for obtaining a current of electricity during definite periods of time for producing electric light and for other purposes.
4,559. D. G. Fitzgerald. London. Improvements in voltaic batteries.
4,566. W. L. Preece and J. Sayers. London. An improved method of distributing electricity for lighting purposes.
4,569. W. F. Dennis. London. Improvements in metallic telegraph poles.

March 16, 1889.

4,586. A. Milton, H. W. Bishop and F. Brown. Walsall. An electric light switch.
4,586. S. Naylor. Halifax. A portable electric alarm clock.
4,623. J. Farquharson. London. An improved metal reflector for electric search lights used in ships of war.
4,642. E. A. G. Street. London. Improvements in apparatus for measuring and registering the consumption of electric energy.

LEGAL INTELLIGENCE.

Chamberlain v. The Midland Electric Light Company.

A motion to rectify the register of this Company by striking off the name of Mr. Arthur Chamberlain, of Birmingham, as the holder of 2,074 shares of £10 each came before Mr. Justice North in the Chancery Division last week.—Mr. Birrell, in support of the motion, said that there was no contest as to the facts of the case. The only question was whether or not, having regard to the circumstances under which those shares were issued, it amounted to an issue of shares at a discount. The point turned upon a clause of an agreement dated April 4, 1887, by which the Company assumed the liability and undertook to repay all moneys Mr. Chamberlain might advance for the purposes of the Company, an account to be struck on the 31st of December, 1887; and that all moneys owing should be repaid, together with interest at 15 per cent. When the balance was struck it was found that the Company was indebted to Mr. Chamberlain in a sum of £18,041. 5s. 11d., which, with the interest, amounted to £20,740. Mr. Chamberlain elected to take shares instead of cash, and accordingly 2,074 £10 shares were allotted to him. Both Mr. Chamberlain and the company had since been advised that the transaction was equivalent to the company selling its shares at a discount, and was therefore obnoxious to the rule of the Court. The company was a very prosperous one, and both they and Mr. Chamberlain were anxions to have the opinion of the Court on the matter, the sole object of the application being to ascertain what the position of the parties was.—Mr. Parker appeared for the Company, and said he was instructed to leave the matter entirely in the hands of the Court.—His Lordship, in giving judgment, said that under the agreement Mr. Chamberlain was to get back the sums he had advanced, either in cash with interest or payment in shares, with equivalent interest in shares for the whole year. It was quite clear, therefore, that the allotment in shares must be for a greater amount than the cash could have been. The shares were therefore issued at a discount. The issue was therefore void, and he made an order removing Mr. Chamberlain's name from the list of contributories of the company in respect of the shares in question.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—THURSDAY, March 28.

In Committee of Supply on the vote of the sum of £2,085,616 to defray the salaries and working expenses of the Post Office Telegraph Service, attention was drawn by several members to the abuse of the free service message system by the railway companies, the yearly loss occasioned thereby amounting, it is alleged, to £50,000. The loss upon press messages was also stated to be as much as £200,000 a year, the rates charged for them being altogether inadequate. Mr. SHAW LEFEVRE questioned these figures, but recommended the commutation of the railway companies rights in respect to service messages. Mr. HENNIKER HEATON advocated the statements of Post Office accounts being formed on commercial principles, when the actual revenue would be found to be far better than it appears to be. The introduction of the telephone into every post office, and the adoption of half rates for night messages, were advocated by Mr. Labouchere.

Mr. RAIKES, the Portmaster-General, in replying to these observations, began by explaining the conditions under which the staff of the Submarine Telegraph Company were being taken over into the Post Office Telegraph Service. With regard to the acquisition of the business of that company he was not yet in a position to say what sum was to be paid to the company for plant and goodwill. Though they were on the eve of arriving at a settlement there was yet one nation, at all events, which desired further information before the ratifications of the convention were exchanged. He believed, however, that the committee and the country would be very well satisfied when they came to know the terms on which it was proposed to acquire the cable. Reference had been made by some hon. members to the painful but constantly-recurring subject of the loss entailed on the country by the purchase of the telegraphs. He was able to refer to a very gratifying diminution of that loss in recent years. The deficit of 1887, upon which the select committee commented last year, amounted to nearly half a million, but the accounts for 1888 showed that the deficit was only £6,000 in that year. He hoped that next year the small deficit of the previous year would be turned into a large sum on the other side of the account, and with the prospective profits from the submarine telegraphs now taken over, he trusted the profits would be very largely increased. He thought the figures of the last ten years would be of interest to the Committee. In 1879 the profit upon the working amounted to £280,000; in 1880 it was £296,000; in 1881, £325,000; so that that year the Service was within £1,000 of paying off the interest; the year following, 1882, the profit fell to £213,000; in 1883 it fell to £184,000; and in 1884 there was a deficit of £19,000; in 1885 there was a deficit of £36,000; in 1886, a deficit of £45,000; in 1887, a deficit of £145,000; and last year, 1888, a deficit of £6,000, which was the smallest deficit since they had got on the wrong side of the account. He ventured to believe that next year would see a substantial sum on the other side of the account. The deficit which began in 1884, was coincident with the extension of the telegraph service and the increase of telegraph salaries. Although the sixpenny telegrams had been a very great obstacle for some time, he trusted that obstacle was now surmounted, and that they were now on their way to earn a profit (hear, hear). The deficit of £145,000 in 1887, although due in some degree to the sixpenny telegrams, was in a large degree due to extraordinary expenditure in that year, which would not occur in following years. With regard to the loss on railway messages, he agreed that there had been a great departure from what must have been the original intention of Parliament (hear, hear). He did not think that Parliament could have contemplated that within twenty years the number of those messages would be multiplied tenfold. He should always be glad to extract a *quid pro quo* from the railway companies by enforcing upon them the necessity of giving greater facilities to the public, and he was quite aware that the private Bills coming before Parliament always afforded an opportunity of raising a question of that kind. As to how far the railway companies ought to be made to pay for the facilities given to them by Parliament he would not like to say. With regard to Press messages, they were very well worthy of the consideration of the department and of the public. He must demur to the exact phrase of "loss of £200,000 on Press messages." He thought that was not the most correct way of referring to that part of the question (hear, hear). There was no doubt that if Press messages were sent at the ordinary rates charged to the public the Department would receive £200,000 a year more; but if the same rates were charged to the Press as to the public many of those messages might never be sent at all, and the Department might not receive anything like £200,000 more than at present (hear, hear). That, no doubt, operated largely on the mind of Parliament and of the Ministers who were responsible for that part of the matter, as well as the question of the public convenience and benefit, quite apart from the personal profits of owners of newspapers which might result from cheap telegraphic rates to newspapers (hear, hear). The hon. member for Nottinghamshire made reference to both those questions, and he was extremely grateful to the hon. member for calling attention to the recommendation of the committee that there should be a more strict adherence to commercial principles, and he would be extremely obliged to hon. members if they would assist him in carrying out that recommendation and aid him in resisting applications from those members who applied for every form of uncommercial arrangement for the benefit of the particular localities they represented (hear, hear). He thought it might be sometimes desirable, not so much in the interests of particular localities as in the interests of the general public, to carry out telegraphic works in connection with very distant parts of the Empire which were not strictly remunerative (hear, hear). For instance, in some places in the Highlands of Scotland telegrams are very few, and the offices not likely to be self-supporting, but it was absolutely essential to the living of the people that they should have ready means of telegraphing for salt to salt their fish, upon which the existence of some of the natives might be said to depend. He thought there were a few cases also where the same thing had been done in the North and West of Ireland. He was quite sure the committee would not object to such expenditure, which was the exception from what he thought an excellent general rule (hear, hear). The hon. baronet the member for the Lichfield Division had urged the increase of the number of telegraph offices at railway stations. He found that there was a great objection on the part of railway companies to their servants acting as servants of the Post Office; and it was not desirable to force upon them duties which would interfere with their first duty. It would not, therefore, be easy to increase the number of telegraph stations in this direction. The hon. member for Falkirk had brought forward the question of half-rates for night messages. The present rate at which messages were transmitted was barely remunerative and it would be more than doubtful whether the revenue would stand the strain of messages at half-rates. He would remind the hon. gentleman that the American initial rates were very much higher than ours. Where the rate was 2d. or 2½d. a word it was possible to send at half-rate, but he could not hold out any hope that such a suggestion would be accepted in this country, where the charge was only a halfpenny a word. The tendency of messages was to get shorter and not longer. The average amount per message was now distinctly below 8d. It was 7·9d. And as the tendency was in that direction it was likely to be still further developed as time went on. Before the 6d. telegrams were introduced the average was 1s. 1d. per message. He did not think that the state of the revenue of the Department would justify him in holding out any hope with regard to a cheaper rate of telegraphic transmission. As to the telephonic system, the Courts had declared it to be a part of the Government monopoly in telegraphs. His predecessor (Mr. Fawcett) unfortunately stated in public that steps would not be taken by the Government to enforce the rights which that judgment gave them, and a state of things had thereby been created which required very careful handling so far as the Department was concerned. The patents, however, were likely to lapse very soon, and when they had run out that would be the time to make arrangements, which he trusted would differ in almost every respect from existing arrangements. With regard to telephones being put into post offices, that was subsidiary to the larger question. In some parts of England the telephonic system was under the control of the Government absolutely, and there it was of course comparatively easy to make arrangements such as had been indicated. So long as the telephone companies continued to ply their trade, it was not desirable, he thought, that the Government should commit itself to arrangements which might seem in any way to recognise or establish a vested interest, which he for one could not admit existed. The grievance of the public in this matter ought, no doubt, to be removed as soon as possible, and it should be done upon terms satisfactory to all parties. He congratulated the Committee upon having taken a step which had been looked forward to for many years by all who were anxious to extend our telegraphic system—the step of sanctioning the acquisition of the system of the Submarine Telegraph Company, from which he anticipated the most beneficial results alike for the public and for the Department (cheers).

During the discussion which followed, several hon. members expressed a hope that as soon as sixpenny telegrams were remunerative the free

Digitized by Google

addresses, or at all events, a certain number of free words for the addresses, would be restored; and Mr. HENNIKER HEATON complained that the cable companies paid a great deal too little, considering the profits they made, for the rental of the Post Office land lines.

Mr. RAIKES, replying, said that the estimated cost of reverting to free addresses was no less than £400,000 a year, and he would be a bold Minister indeed who would hold out a prospect of incurring such a loss in restoring the old system. His hon. friend wished them to institute a roving commission to ascertain how the Transatlantic and other submarine cable companies transacted their business. He did not see how such an inquiry could be prosecuted, as we had no right to overhaul the books of those companies. Therefore, he could hold out no hope of such an inquiry being instituted. There was no intention on the part of the Government to acquire the telephones by purchase. He might, in conclusion, take this opportunity of referring to the grievous loss the telegraph department had just sustained in the death of Mr. Patey, who was a most competent public servant (hear, hear). His loss was deeply felt and his memory was endeared to all who had had the advantage of serving under him (hear, hear).

COMPANIES' MEETINGS & REPORTS.

Western Counties and South Wales Telephone Company (Limited).

The fourth annual meeting of this Company was held at Bristol on the 27th ult., the Chairman (Mr. Charles Nash) presiding.

The SECRETARY (Mr. H. F. Lewis) having read the notice convening the meeting.

The CHAIRMAN said that it was customary to take the reports and accounts as read, and he would move that they be approved and adopted. The Directors met the shareholders at a somewhat earlier date that year than last, and upon the whole he hoped they would agree with him that it was a satisfactory report that they were now able to put before them. There were some results of the working during the last three years that he would put very briefly before them. Their gross revenue in 1886 was 27¼ per cent. upon the capital expenditure, in 1887 it was 27¾, and in 1888 it had risen to 28½ per cent. Upon the other hand, the working expenses had decreased during those three years from about 32 per cent. of the gross revenue in 1886 to less than 26 per cent. in 1888. Looking at the net revenue, that yielded a percentage upon the capital outlay of 5½ per cent. in 1886, 7 per cent. in 1887, and 8 per cent. in 1888, the figures being £3,184 in 1886, £6,007 in 1887, and £9,059 in 1888. From 1886 to 1888 the subscribers had very nearly doubled. They were 1,318 in 1886 and 2,610 last year, and the wire mileage had increased during that time very nearly threefold. Then he might add that, with scarcely an exception, at every one of the exchanges there had been a considerable increase in business. The rate of increase no doubt varied much. At Newport it had been more than doubled, at Bath and Exeter it had increased more than 50 per cent., at Cardiff 40 per cent., at Plymouth 30 per cent., at Portsmouth 25 per cent., Bournemouth and Torquay 20 per cent. All that had not been accomplished without very close attention to details, and the Directors had given a great deal of time and thought, and had exercised great supervision over the general working as far as they possibly could. He need not say that the result was largely and principally due to the energy and ability of the secretary, Mr. Lewis. His work, he could assure them, had not been a light one, to keep in view the working of thirty-four exchanges, extending from Shrewsbury in the north to Plymouth in the south, and westward from Portsmouth to Swansea and Llanelly. He did not think that it was necessary to say much about the future, but he might say this much, that their large district was very far from being covered; there was still a great deal of ground that they hoped might be profitably occupied, and those towns where business was already carried on admitted of an extension of business. Then again there was the trunk connection that they were looking forward to, to London, Birmingham, and other places in the north, which might have the effect of adding considerably to their local subscribers as well as bringing a considerable number of messages upon the trunks themselves, and all that, he thought, led them to the conclusion that there was room for considerable further development, and he could only say that it was the aim of the board to foster and develop it as far as they could.

Mr. MARK WHITWILL (Deputy-Chairman) seconded the resolution, and said that they would see that the business was growing fast, and it would be further developed as fast as they thought prudent. They looked forward with hope and confidence to the future.

The motion was carried.

The CHAIRMAN then moved—

"*That a dividend of 6 per cent. be paid to the preference shareholders, and that the amounts already paid by the Directors on account of such dividend be approved and confirmed.*"

Mr. T. POLE seconded the motion, which was adopted.

The CHAIRMAN then moved—

"*That a dividend at the rate of ½ per cent. per annum be paid upon the ordinary shares, payable on the 30th inst.*"

Mr. H. FEDDEN seconded the resolution, which was also carried.

The CHAIRMAN said that Mr. Mark Whitwill retired by rotation from the directorate, and was eligible for re-election.

Mr. A. POLE proposed Mr. Whitwill's re-election, which was seconded by Mr. STUCKEY, and carried.

Mr. WHITWILL having returned thanks,

The CHAIRMAN mentioned that Commander Douglas Forsyth, R.N., one of the Directors, felt that, owing to the distance he lived from Bristol, he was unable to continue upon the directorate. He thought they ought not to allow Commander Forsyth to retire without an expression of thanks for his past services.

Commander FORSYTH suitably acknowledged the compliment, and spoke of the valuable assistance he had always received from Mr. Lewis and the staff generally.

The CHAIRMAN proposed that £200 be placed to the special reserve fund, making that fund amount to £1,200.

Commander FORSYTH seconded the motion, which was carried.

Mr. MARK WHITWILL proposed the re-election of the auditors, Messrs. Hudson Smith, Briggs and Co.

Mr. H. FEDDEN seconded the motion, which was carried.

The CHAIRMAN said that, owing to the work of the auditors having increased, it was proposed to increase their remuneration to £99. 15s.

Mr. T. POLE seconded the resolution, which was agreed to.

The CHAIRMAN said that they were all aware that there had been some most calamitous floods in Bristol, and there had been large subscriptions given, not only by individuals and firms but by public companies, and he did not think that their telephone company should be left out. He did not know how the members would regard it, but the suggestion of the Directors was that they should contribute twenty guineas to the relief fund, to be paid out of the balance that was carried over to last year's accounts.

Mr. REED proposed that they should give twenty guineas.

Mr. WHITE seconded the motion, which was adopted.

Mr. J. INSKIP proposed that the remuneration of the Directors should be increased from £400 to £500.

This was seconded by Mr. REED, and adopted.

Liverpool Electric Supply Company (Limited).

The sixth annual meeting of the shareholders of this Company was held in the Law Association-rooms, Liverpool, on Tuesday, March 26th, Mr. A. H. Holmes presiding.

In presenting their sixth annual statement, the Directors reported a considerable extension of the Company's business during the past twelve months, and the accounts showed the amount of net profit available for dividend, including the balance brought forward from 1887, to be £1,788. 0s. 3d. Out of this sum the Directors recommended the payment of a dividend of 3 per cent., absorbing £1,067. The capital expenditure during the year on land, buildings and plant, including a proportionate charge for general expenses, amounted to £20,919. 16s. 4d. The greater part of these additions could not be brought into remunerative working condition during the year, but the effect on the earnings of the Company might be judged from the fact that the amount received for the supply of electricity during January, 1889, exceeded by about 20 per cent. the average monthly receipts for last November and December, and amounted to nearly four times the revenue derived from this source in January, 1888. In the month of June the Board of Trade issued to the Company a license authorising them to supply electricity by means of underground mains throughout certain portions of the city, and the Directors had opened negotiations with the local authority with the view of obtaining for the Company a Provisional Order, so as to secure the advantages afforded by the amended Electric Lighting Act of 1888. They confidently hoped that in the interests of the public as well as the Company these negotiations might be brought to a successful issue. The total number of incandescent lamps now in connection with the Company's system is three times greater than at the commencement of last year. The Directors have secured a suitable site in Highfield-street for the extension of the Company's most important station. Negotiations had also been completed for the purchase of a very favourable site for a central station for the Lime-street and residential districts of the city. The Company had in hand numerous orders for electric fittings, and had secured the contract for the electric lighting of two new steamers now building for the White Star line.

The CHAIRMAN, in proposing the adoption of the report, said the Company were proceeding with the underground mains as they were required by customers. Bold-street had been omitted from the area of license, but the Company were in negotiations with the Watch Committee in order to have the supply extended to that thoroughfare, and also to take advantage of the new Act of 1888. In their negotiations with the Watch Committee he had no doubt they would succeed. The position of the Company as a dividend-paying concern they knew. The initial expenditure was necessarily very large, but their receipts were increasing, and the Directors had written off a large sum for depreciation. To provide for the expenditure on underground mains and three new stations they would have to call up the remainder of the share capital.

Sir JAMES PICTON seconded the motion, and the report was adopted unanimously.

Messrs. A. H. Holmes and Mr. J. S. H. Banner were re-elected directors, and Mr. W. Jackson auditor.

Edmundson's (Limited).

The statutory meeting of this Company was held on their premises, 19, Great George-street, Westminster, on the 28th inst.

Mr. John R. Wigham, J.P., Chairman of the Company, presided.

The CHAIRMAN congratulated the shareholders on the satisfactory position of the Company. He stated that a larger amount of trade had

Digitized by Google

been done since the acquisition of the business by the Company, dating from July last, than in the whole of any year during which the trade had been carried on by their predecessors, and that the prospects of the Company, in view of the advances that are being made in electric lighting, are exceedingly encouraging. He also mentioned that the shares had been all taken up within a few days after the issue of the prospectus, and that they are held exclusively by the customers and the Directors, many of the former being amongst the largest consumers of electric light in this country.

The out-going Directors were all re-elected.

The Eastern Extension, Australasia and China Telegraph Company (Limited).

Report and accounts of the Directors for the half-year ended 31st December, 1888, to be submitted to the thirty-first ordinary general meeting, to be held at Winchester House, on Wednesday, the 10th inst., at two o'clock:—

2. The gross receipts, including Government subsidies, have amounted during that period to £238,854. 14s. 4d., against £232,660. 0s. 11d. for the corresponding half-year of 1887.

3. The working and other expenses, including £23.883. 2s. 7d. for cost of repairs to cables, and expenses of ships, absorb £71,519. 7s 4d. against £69,570. 16s. 5d. for the corresponding period of 1887, leaving a balance of £167,335. 7s. 0d. From this is deducted £3,049. 15s. 0d. for income tax, £41,585 for interest on debentures and contributions to sinking funds, and £4,492. 7s. 11d. for rebuilding staff quarters at Cape St. James, leaving £118,198. 4s. 1d. as the net profit for the half-year, which, with £47,903 4s. 1d. brought forward from the previous half-year, shows an available balance of £166,101. 8s. 2d.

4. One quarterly interim dividend of 1¼ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount, making, with the interim dividends paid for the first half-year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 3s. per share, or 1¼ per cent., making a total distribution of 6¼ per cent., for the year 1888. The balance of £66,101. 8s. 2d. has been carried to the general reserve fund, which, after being credited with the interest on investments received during the half-year, and debited with the cost of the partial renewals of the Java-Australian cables off the Lombok Straits, amounting to £18,986. 19s. 5d., now stands at £690,454. 18s. 4d.

5. In pursuance of the conditions upon which the issue was made 119 of the Company's Five per Cent. Debentures of 1880 were drawn by lot on the 11th ultimo for payment at par on the 1st May proximo.

291 of the Company's Five per Cent. Australian Government Subsidy Debentures were also drawn on the 1st instant for payment at par on the 1st July next.

(Numbers of the drawn debentures will be found in our advertisement pages.)

6. The Company's maintenance ships have been employed on various repairs during the half-year under review, as shown in abstract C, but no interruptions of a serious nature have taken place beyond those on the Australian section referred to in the last report, and subsequently for a few days whilst carrying out the renewals off the Lombok Straits. All the Company's cables are now in good working order.

7. Since the close of the half-year telegraphic communication with the Australasian Colonies has been greatly strengthened by the extension of the Company's system from Java to Western Australia. This extension, as explained in the last report, gives the Colonies a third cable to Java, and brings into use the Western Australian land lines as an alternative system to the South Australian overland line, thus minimising the risk of interruptions in the future.

8. Your Directors have the pleasure to report that an agreement has been recently concluded with the Government of Tasmania, by which the Company's exclusive privilege of telegraphic communication between Tasmania and Victoria, which by effluxion of time would expire next year, has been extended for a further term of twenty years. The subsidy of £4,200 per annum, payable to the Company by the Government, will be continued for the same period.

9. In accordance with the Articles of Association, Sir James Anderson and Francis Augustus Bevan, Esq., retire by rotation, and, being eligible, offer themselves for re-election.

1 . The auditor, Mr. Henry Dever, retires, and offers himself for re-election. The auditors, Messrs. Quilter, Welton and Co., also retire, and offer themselves for re-election under their new style of Welton, Jones and Co., adopted since the death of Mr. Quilter.

The Oriental Telephone Company (Limited).

Report of the Directors for the year ended 31st December, 1888, to be presented at the ninth ordinary general meeting of the Company, to be held at the Cannon-street Hotel, London, E.C., on Tuesday the 16th inst., at one o'clock.

The revenue account shows a balance at credit of £6,651. 12s. 8d., which has been transferred to profit and loss. Including the sum of £3,602. 16s 1d. brought forward from the previous year, the amount available for disposal is £10,254. 8s 9d., which the Directors recommend should be dealt with as follows: To place £2,500 to a reserve fund; to apply £3,000 in final extinction of preliminary expenses; to write off £341. 4s 8d for depreciation of stores and balance cost of reconstruction of the Rangoon Exchange, and to pay a dividend of 3 per cent, free of income-tax, on the paid-up capital of the Company, other than the vendors' shares, carrying forward £685. 18s. 11d.

The Directors consider that until some satisfactory arrangement has been come to with the holders of the vendors' shares, the soundest policy is to pay small dividends and to build up a reserve fund sufficient to meet whatever contingencies may happen.

The amounts received and to be received from the Indian companies for dividends for the past year on the shares held by this Company, and which have been brought into the revenue account, include £150 belonging to 1887, and a small surplus arising on final settlement of the guarantee to the Bengal Telephone Company.

The returns from the Indian companies show a moderate improvement, but the business in India generally is heavily weighted by Government and local taxes; and the continued restrictive policy of the Indian Telegraph Department acts detrimentally. An alteration in the management of the Bengal Company, carried out by your Directors, has effected considerable saving in the working expenses of that Company.

The Telephone Company of Egypt maintains its revenue, and has declared a dividend of 6 per cent. for the past year, free of income tax, carrying forward a sum of £1,069 14s. 11d. The Directors of that Company have placed £5,000 of debentures in Egypt, bearing interest at 6 per cent., and were thereby enabled to pay off the loan due to this Company.

At Rangoon and Singapore the branches are making satisfactory progress; but at Madras, Colombo and Mauritius the revenues remain stationary.

The China and Japan Company's accounts for the past year exhibit a small surplus after paying debenture interest.

The question of the Company's rights in the Australasian Colonies has been settled by an agreement being come to with the Western Electric Company of Chicago, whereby that Company has undertaken to pay certain royalties. A payment has already been received in respect of these royalties, which has been applied in part reduction of the outlay incurred.

The retiring Directors are Mr. Henry Grewing and Mr. Thomas Lloyd, both of whom being eligible offer themselves for re-election. Messrs. Deloitte, Dever, Griffiths and Co., the auditors of the Company, retire, but offer themselves for re-election.

Electrical Power Storage Company (Limited).

Report of the Directors, to be presented to the shareholders at the eighth ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on Wednesday, the 10th inst., at 12:30 p.m.

The gross profit for the year is £13,273. 15s. 3d., which includes all royalties and receipts, the bulk of this profit being derived from the manufacture of storage batteries and special apparatus in connection therewith. The expenditure for the year, including debenture and other interest, &c., is £11,709. 3s. 8d., and the balance added to the amount standing to the credit of profit and loss, makes the sum of £8,372. 13s. 6d., out of which the Directors would recommend a dividend were it not that the increasing volume of business demands a larger working capital, and the best method of securing this has been, and is, a subject of anxious consideration by the Directors.

During the year under review there was a considerable increase in the Company's business, while, as compared with the corresponding period of the year 1888, the orders received this year up to date have already nearly doubled. To meet this rapid growth of business it has been necessary to make a considerable outlay on the Millwall Works, and to increase the staff. This additional outlay amounts to £1,827. 3s. 6d.

The Directors are glad to state that the Company is not engaged in any litigation.

Among the many new electric light installations employing storage batteries may be mentioned the Lyric Theatre, where a 1,000 sixteen candle-power E.P.S. battery is erected; the London Joint-Stock Bank, the private residences of Sir Henry Meux, Bart.; J. Fletcher Moulton, Esq., Q.C.; Alfred de Rothschild, Esq.; Dr. John Hopkinson, F.R.S., and the Royal Arsenal, Woolwich.

The new form of battery, known as the "1888" type, continues to give satisfaction.

A number of scientific and technical institutions have adopted accumulators, viz., the Central Guilds of London Institute, Millard Laboratory, Oxford; Cavendish Laboratory, Cambridge; University College of Wales, Cardiff; Heriot-Watt College, Edinburgh; Queen's College, Cork; and the University of Japan, Tokio.

A gold medal was awarded the Company at the Brussels Exhibition for their exhibit of storage batteries and accessory apparatus.

Central station lighting, which the Directors have regarded as ultimately the main source for the use on a commercial scale of storage batteries, is at last beginning to attract the serious attention of the public, and it is hoped that many of the applications for provisional orders now before the Board of Trade may be granted and confirmed by Parliament during the current year, as, until that result is attained, the full effect of the alteration of the law by the Electric Lighting Amendment Act of 1888 cannot be felt. The only Company in the metropolis which possesses the requisite Parliamentary powers is the Chelsea Electricity Supply Company, under 50 Vic., cap. 18, with which Company a contract has been made for the supply of a large accumulator battery for its central station and sub-station; the Chelsea Company will work its central station on the distribution system of the E.P.S. Company, and will supply light during the present month. Batteries have also been furnished for central stations in various parts of the kingdom.

Accumulators for train lighting have been in demand. Extensions have been made to the lighting plant of the London, Brighton, and South Coast and Great Northern Railways, and batteries for this purpose have also been furnished to the Midland, London and North Western, and Taff Vale Railways, and South Western Railway of Russia. For ship and yacht lighting a new type of accumulator has been designed, and has been supplied to the British navy, the Italian and Danish navies, and to yachts, among which may be mentioned the "Mohican," "Wanderer," and "Torfrida." The lighting of forty omnibuses of the London General Omnibus Company is carried out by means of E.P.S. accumulators.

In surgical batteries a new use for accumulators has been found, and a portable type battery has been made from which current is supplied to cauteries, induction coils, motors, and lamps; and to give special facility for recharging in London, Messrs. Coxeter and Sons, the surgical instrument makers, have established a charging station in Grafton-street, W.C. For the propulsion of electric tramcars a large order has been received from the Electric Traction Company for storage batteries for six cars for working on the Barking line. An interesting experiment has also been made by Mr. Sandwell in propelling tramcars by batteries carried on a separate truck or bogie.

In electric launches, worked from storage batteries, progress has been made, as E.P.S. batteries are used in the "Maldon" and the "Viscountess Bury," the latter a boat 65ft. long by 10ft. beam. E.P.S. accumulators are also employed by Mr. Radcliffe Ward in his method of propelling vehicles on ordinary roads by electricity. Throughout Europe the advantages of the use of storage batteries are gradually being realised, but several causes have tended to delay their general adoption. This year the Directors hope the amount of royalties will be substantially increased, as the various companies and firms with whom arrangements have been made to manufacture E.P.S. batteries under royalty have completed the erection of their factories. These are to supply the batteries in Germany, Austria, Hungary, France, Russia, Finland, and the Scandinavian countries.

The Electrical Accumulator Company of New York is pushing the business vigorously in all directions on the American Continent, and a pamphlet published by that Company, showing how successful it has been in establishing its patent rights in the United States, will be read by the shareholders with much interest.

The retiring Directors are Sir Daniel Cooper, Bart., and J. Irving Courtenay, Esq., who, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever and Co., also offer themselves for re-election.

NEW COMPANIES REGISTERED.

THE HALIFAX MUTUAL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—Registered by C. Doubble, 14, Serjeant's-inn, Temple, E.C., with a capital of £20,000 in £5 shares. Objects, to generally carry on the business of electrical engineers, manufacturers, contractors and electric lighting, and to acquire concessions from or with Governments, municipal or other authorities, for the supply and produce of same. The number of directors shall not be less than three nor more than seven. Remuneration to be determined in general meeting.

THE NEW PORTABLE ELECTRIC LAMP AND POWER SYNDICATE COMPANY (LIMITED).—This company have resolved to wind up, and Mr. James A. Hays and Mr. Benjamin Nicholson are appointed joint liquidators.

PLANET ELECTRICAL ENGINEERING COMPANY.—This company was registered on the 26th inst., with a capital of £20,000 in £5 shares, to carry on the business of an electric light company in all branches. One of the original subscribers is Mr. A. L. Shephard, of 2, Victoria-mansions.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY.—At a meeting of the Board of this Company, held on March 29, it was resolved to declare an interim dividend for the quarter ending March 31, 1889, of 12s. 6d. per cent. on the Ordinary Stock and 25s. per cent. on the Preferred Stock, less income tax, payable on May 1 to the stockholders registered on the books of the Company on April 1, 1889.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of March was 5,992, estimated to produce £4,500, against 4,919 messages, producing £3,835 in the corresponding month of last year. The traffic receipts for the month of December, estimated at £3,500, realised £3,508.

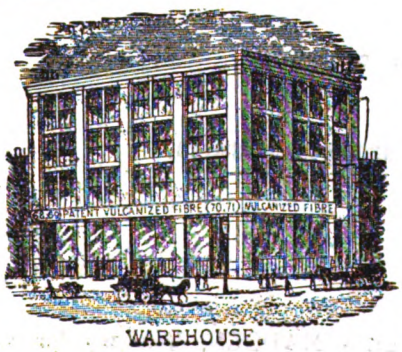
DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of March amounted to £2,129, as compared with £1,900 last year.

TELEPHONE COMPANY OF AUSTRIA.—The directors have declared the usual half yearly dividend to 31st March on the preference shares, at the rate of 6 per cent. per annum.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the month ended 31st March, 1889, amounted to £5,950.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this company for the half-month ended March 31st, 1889, were £3,714, against £3,714 for the corresponding period last year.

THE NON-CONDUCTOR OF ELECTRICITY.

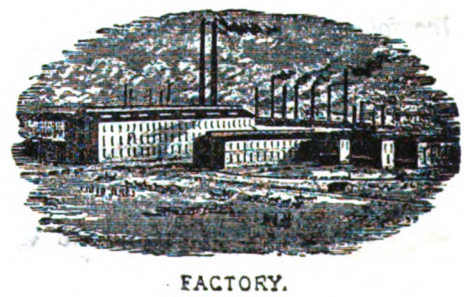


WAREHOUSE.

VULCANISED FIBRE,
PATENTED.

This new material is supplied in two qualities, Flexible and Hard.
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.
It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.
The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.
Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 569.—Vol. XXII. FRIDAY, APRIL 12, 1889. Price Fourpence.

NOTES.

The progress made during the week by the Board of Trade Inquiry is, we suppose, as great as could reasonably be expected. The evidence on behalf of the "London" and the "Metropolitan" Companies has been completed, and Mr. Moulton (in a speech of marked ability, full of keen satire and accurate science) has opened the case on behalf of the Chelsea Electricity Supply Company. In so doing, he intimated that he put himself forward as the champion of all the companies who offered to furnish a direct current supply. The case on behalf of the storage battery could scarcely have been better put, although, of course, no new argument was introduced.

A very considerable amount of time is wasted at the Inquiry by the attempts of unscientific counsel to extract technical information from directors, managers, and other unscientific witnesses; but the representatives of the Vestries and other local authorities are eager to pick up all the knowledge they can. There is a general impression that The London Electric Supply Company intends to pump the electric fluid from Deptford through Mr. Ferranti's tubular mains at an enormous pressure, which, but for the pedantry of the scientific gentlemen, might be expressed in pounds per square inch. It is obvious that the electric fluid will squirt out at the joints if these are not carefully made, and, therefore, the road surveyors are most pertinacious in their inquiries on this point.

After prodding the insulation with penknives and thumb-nails some of the more practical vestrymen think that, considering the present prices of copper and the large capital of the company, it would be doing things in a more handsome style if the mains were made of solid copper tubes.

It is rather a pity that, as the Inquiry did not sit on Tuesday, Thursday, and Friday this week, there were not a few lectures on elementary electricity delivered on those days for the instruction of some of the people engaged.

The Committee of the Electrical Section of the Chamber of Commerce has lost no time in taking action upon the suggestion of the Chairman as to the appointment of a permanent official, and the arrangement has been carried out on the lines indicated in our last issue. A special meeting of the Committee was held on Saturday last, when, as we are happy to announce, the appointment was offered to, and accepted by, Mr. A. P. Trotter. As to Mr. Trotter's many qualifications for the position we need not stay to speak; we feel sure that the appointment is one which will be received with universal satisfaction, and which the Section will have no cause to regret. We may add that Mr. Trotter's business address is No. 2, Victoria-mansions, Westminster (Telephone No. 3086). The exact nature and extent of the duties attaching to the office have not yet been clearly defined, but it is quite evident that Mr. Trotter will find plenty of work immediately to hand in looking after the general interests of the Section.

Our readers will be glad to learn that the Board of Trade has signified its willingness to receive a deputation from the Electrical Section on the overhead wire question. It has, however, been considered desirable to postpone the matter until the conclusion of the present inquiry.

Perhaps the most interesting point in Prof. Forbes' report to the Electric Lighting Committee of the Paddington Vestry is contained in the proposal to obtain the whole of the fuel for maintaining 15,000 50-watt incandescent and 400 arc lamps from the parish dust-bins. Prof. Forbes has himself designed a furnace for the consumption of refuse, for which he expects to obtain a horse-power for about 15lb. of fuel of this class per hour. It is also suggested that the clinkers be ground up to make paving stones, as is already done at Southampton. The arc lighting is to extend over every court and alley of the district, and is to cost in the end £9,044 per annum, or about £4,000 more than the present gas lighting. Prof. Forbes further estimates that the Vestry will be able to supply the private consumers at 3s. 6½d. per Board of Trade unit—or 4¼d. in the old measure. The estimates are not given in sufficient detail to allow of much criticism. We notice, however, that as many as 50 lamps are allowed on the average for each consumer, and, what is more striking, the arc light cables are to be purchased and laid (not including the conduit) for £100 per mile. We are glad to see that the estimated revenue is based upon the reasonable figure of 700 lamp-hours per lamp per annum.

We publish this week a series of Memoranda by Dr. Oliver Lodge in connection with the proposal to establish experimental lightning conductors at certain telegraph stations abroad where thunder-storms are periodic phenomena. We have already stated that the Eastern Telegraph Company has expressed its

Digitized by Google

willingness to lend assistance, and we have also received letters from members of that Company's staff who are anxious to take part in the observations. We have, therefore, every reason to anticipate that results of considerable scientific and practical importance will eventually be achieved. As the observations will be carried out by duly qualified electricians, there should be no reason to fear any mishap to those concerned. It is sufficient to remark that the arrangements proposed will be as far as possible self-recording in character, and we need hardly say that in every case the observer will be careful to give the experimental conductor a wide berth during a thunderstorm.

On this subject we may remark that in the Report of the Lightning Rod Conference (1882), p. 2, we read:—"A man may with perfect impunity clasp a copper rod an inch in diameter, the bottom of which is well connected with moist earth, while the top of it receives a violent flash of lightning." Now this can only have been a pious opinion on the part of the members of the Conference, and we have now good reason to believe that the experiment would be foolhardy in the extreme. On the same page we are told that if the conductor be of sufficient height, of ample dimensions, and well connected to earth, it "might even be surrounded by gunpowder in the heaviest storm without risk or danger." This assertion was made, we need hardly say, before the discovery of the "side-flash," but it was perhaps a little unscientific on the part of the Conference to make such dogmatic assertions for which direct evidence was certainly wanting. In the light of present knowledge we can only conclude that either event might happen a dozen times with impunity, and on the thirteenth a catastrophe might arise. The fact, however, of such statements remaining on record as the authoritative expression of the opinion of the leading electricians of the day emphasises the need of thrashing out the whole subject with the least possible delay.

In reference to the progress made with negotiations for the amalgamation of the three leading Telephone Companies, which we recently announced, the following is the text of a circular issued by the Lancashire and Cheshire Telephonic Exchange Company:—

"Manchester, 5th April, 1889.

"For the past eighteen months your Board of Directors have been in frequent consultation with the United Telephone Company and the National Telephone Company with a view to amalgamation. The details of the amalgamation have not been finally settled, but it has been provisionally arranged that the basis of such amalgamation shall be the market value of the respective shares, estimated as follows:—United Company, £15; National Company, £6; and £1. 11s. 6d. as the value of each £1 share in the Lancashire and Cheshire Company. When the necessary formalities are completed, a circular will be forwarded inviting you to attend an extraordinary general meeting of shareholders to consider and (if thought fit) to approve of the draft agreement which will then be submitted.

"Joseph Thompson, Chairman."

We announced a fortnight ago that the United Telephone Company had commenced an action against the New Telephone Company. We may add that a separate action has been entered against each Director individually. We have reason, however, to believe that the case will be settled out of Court.

A statement has appeared in the daily papers to the effect that M. Courlon (Chef des Postes et Télégraphes) had "ordered a series of experiments to be undertaken with a view of establishing telephonic communication between London and Paris." This announcement is obviously incorrect as it stands. It is true that the question of the desirability of establishing such communication has been taken into consideration by the two administrations concerned, but nothing has yet been decided, pending reports from the technical officers. A special cable would of course be required.

In saying last week that nobody had protested against the new rates to the Continent we reckoned without our Henniker Heaton. That eminent authority on cable charges had written his protest, but it did not appear in *The Times* until the morning we published our editorial note. Even Mr. Henniker Heaton, however, has failed to spot the particular point on which we commented. What he complains of is that the word rate to France has been reduced only to 2d. instead of to 1d. as it ought to have been. We fail to see why it ought not to have come down to a halfpenny on his showing; for his argument is based on the absurdity of charging 2d. across the Straits of Dover while charging only ½d. across the Irish Channel. Perhaps when Ireland gets Home Rule that anomaly may be rectified. But, meanwhile, Ireland enjoys a halfpenny rate with England and Scotland because she is part of the United Kingdom, which is content to pay a trifle more than it otherwise need pay in order to keep up unity and uniformity of things. That higher rates prevail beyond national frontiers may be absurd, but they are not peculiar to this country; and if it were not for the fact that Mr. Henniker Heaton would be nobody if he had not a grievance against the British Post Office, we should be unable to understand why he does not "go for" the French, German, and Belgian Governments, who all alike maintain higher rates between each other, and are responsible for the still higher rates through these international cables.

But Mr. Henniker Heaton was mildness itself compared to *The Times* next day. According to that journal, Mr. Raikes has betrayed the British Parliament into sanctioning an agreement without that full discussion of its merits which of course would have persuaded the French Government to reverse the decision it had long ago come to with the several Governments interested. So argues *The Times*; but if nothing better than its own arguments could have been discovered in Parliament they would have convinced not even the British Government, much less either the French, German or Belgian. Why, asks *The Times*, seeing that Anglo-Continental letters are charged only the combined inland postage of the two countries, and nothing for the steam packet—why should telegrams be taxed an extra penny for the intervening cable? The question is self-destructive, since it might be asked of any cable connecting Great Britain with her colonies or with the United States. But as regards the particular case in question, the one practical answer which has probably prevailed is this: Postage is profitable and can afford a margin for unremunerative expenditure. The Telegraphs on the Continent as well as in England are

Digitized by Google

worked at a loss. When the inland tariffs were fixed no account was taken of a large outlay on present and future international cables; and by foregoing any return upon this extra capital the Governments would simply increase the existing losses, and probably perpetuate them; whereas by charging for the cable service now these losses may be recovered and the cables ultimately freed.

In the sad accident which occurred at Deptford on Tuesday morning it was only by the narrowest margin that both Major Marindin and Mr. Ferranti escaped from being numbered amongst the victims. At the moment when the steam-pipe burst Major Marindin had just passed the spot. Had the Inspector been accompanied by the Directors of the Company, as was at first proposed, we should in all probability have had to lament a distressing catastrophe. As it is, one poor fellow was killed on the spot by falling from a staging, though we are pleased to learn that the three men who were scalded are all doing well.

Our New York letter contains this week a detailed account of the important decision just rendered in the United States Courts in the action brought by the Electrical Accumulator Company against the Julien Electric Company, who were alleged to have infringed the patents of Faure and Swan for the construction of secondary batteries. In the end it will be seen that the Swan patents have been declared invalid, and only one claim in Faure's patent has been sustained. Our correspondent is of opinion that this decision practically leaves the Brush patent master of the field. He anticipates a great extension in the use of secondary batteries in the States at an early period.

We believe that the statement published by a contemporary to the effect that the Edison-Swan Company are about to commence an action against the makers of the Sunbeam lamp for infringement is not quite correct. Although we are without authoritative information, we believe it will be found that it is the Cheesbrough, and not the Edison patent, which is in question, and, further, that the makers of the Sunbeam lamp deny that the filaments are flashed. We also have some reason to believe that the matter is in a fair way of settlement out of Court.

St. Martin's-in-the-Fields Vestry.—This Vestry has decided to have the Vestry Hall lighted by electricity.

Italian Telegraph Department.—The King of Italy has recently signed a decree creating a Ministry of Posts and Telegraphs.

Saragossa.—A central station on the alternating current transformer system will shortly be in operation at Saragossa, the dynamos being driven by water-power.

Chelsea Electrical Supply Company.—This company commenced the supply of current yesterday (Thursday) evening, from which period the supply will be continuously maintained,

Telephones in Russia.—A *Standard* telegram mentions that a Franco-Russian Company has been formed to establish telephonic communication between Berlin, Moscow, Warsaw, and St. Petersburg.

The Brooks' Underground Cable System.—We learn that Messrs. Johnson and Phillips have been appointed sole licensees and manufacturers in the United Kingdom of Brooks' underground wires method of laying mains.

The Royal Society.—The Bakerian Lecture was appointed to be delivered yesterday (Thursday) afternoon by Prof. Thorpe, F.R.S., and Prof. Rücker, F.R.S., on a Magnetic Survey of the British Isles for the Epoch January 1, 1886.

The Electric Light at University College.—The library of University College (London), which has for some time past been closed of an evening owing to the damage done to the books by the gas, will we hear be wholly lighted by electricity.

Lurgan.—At a recent meeting of the Lurgan Town Commissioners a committee was appointed "to confer with the gentleman who had introduced electric lighting in Ballymena, with a view to ascertaining the probable cost of electric lighting in Lurgan."

Milan.—A new central telephone exchange will shortly be opened in the Galerie Victor Emmanuel at Milan. The exchange will be capable of accommodating 3,000 subscribers. The entire service will now be concentrated in this building, and several switch rooms hitherto in use will be closed.

A New Post Office Submarine Cable.—The Telegraph Construction and Maintenance Company has just manufactured for the Post Office one of the largest shore end cables which has hitherto been constructed. The cable is a 4-core one, and is very heavily armoured, weighing nearly 28 tons per mile.

Paris.—M.M. Tschierer and Fuchs, of Puteaux, have recently established a central station at 18, Rue Beaubourg, for the distribution of power by electricity. The plant, says the *Bulletin de l'Electricité*, comprises a 110 horse-power horizontal Corliss engine and two Gramme machines, giving 370 amperes and 110 volts.

Harleston.—Messrs. Knights and Stacey have received an order to fit the extensive mills and maltings of Messrs. Edwards and Co. with the electric light. This firm are the agents for the Eastern counties for Spiel's petroleum engine, and have recently given several demonstrations of its suitability to dynamo driving.

Telephonic Directory for the Aberdeen District.—In addition to the usual alphabetical list of subscribers, this directory contains a carefully compiled list of subscribers arranged under their professional and business headings. The lists are accompanied by a map showing the existing and projected system of the National Telephone Company in Central Scotland.

Coast Telegraphs.—In reply to Mr. Johnston, Sir M. Hicks-Beach said, in the House of Commons on Tuesday evening, that the question of telegraphic communication between lighthouses, coastguard stations, and lifeboat stations round the coast was a matter for the consideration of the Post Office and the Admiralty, subject to the Treasury, rather than for the Board of Trade.

Electric Light in Spain.—The central lighting station at Durango (Bilbao) has just started operations, the streets of the town being lighted by 300 incandescents. The towns of Cestova, Arpeilia, and Azcortia, in the province of Guipuzcoa, where water power is available, also contemplate central stations. A central station is also projected for the town of Oreuse.

Barnet.—At the meeting of the Barnet Local Board last Tuesday, the account sent in by the electric lighting contractor was referred back to the Finance Committee for further consideration. Complaint was made of the irregularity of the lighting and the smallness of the allowance made for defects. It was stated that the allowance for the past three months was only 21s. 6d.

Scarborough.—At the monthly meeting of the Scarborough Town Council, held last Monday, the Sanitary and Lighting Committee reported that communications had been received in reference to the electric lighting of the borough from Messrs. Drake and Gorham and from the Anglo-American Brush Electric Light Corporation. The committee had referred the communications to a sub-committee for consideration.

Chelsea Vestry.—At a meeting of this Vestry last week, the surveyor reported that the London Electric Supply Corpora-

Digitized by Google

tion had agreed to all the alterations in its Provisional Order which the Vestry demanded. He would, therefore, like the Vestry to authorise the chairman of the Electric Lighting Committee to attend the Board of Trade inquiry and withdraw the notice of opposition. The suggestion was acceded to.

Accident at Deptford.—About noon on Tuesday last the bursting of a steam-pipe at the station of the London Electric Supply Corporation now in progress at Deptford carried away a staging on which were a number of men, precipitating some of them into a pit below. One man, who had sustained serious injury to his back, died before reaching the hospital, and three other men seriously injured were taken to the Seaman's Hospital at Greenwich.

Overhead Wires.—In the House of Commons on Monday last, in answer to a question of Sir G. Campbell's, Mr. Ritchie said he had communicated with the President of the Board of Trade, who was considering the possibility of making regulations with regard to overhead wires, but no power could be given to local authorities to deal with this matter without legislation, and the Government did not at present propose to introduce a Bill on the subject.

The Birmingham Exhibition.—On the application of Mr. T. C. Sharp the Board of Trade have certified, under the provisions of the Patents, Designs, and Trade Marks Act, 1883, that the Electric and Industrial Exhibition to be opened at Bingley Hall in August is to be regarded as an International Exhibition. The arrangements are progressing satisfactorily, and the demand for space gives promise of an unqualified success being achieved.

International Novelties Exhibition.—An exhibition will be opened on May 29th, in the Central Hall, Holborn, at which it is announced that the latest novelties in the arts, sciences and manufactures which have been produced at home and abroad will be on view. Great care will be exercised by the committee of selection to admit only those exhibits possessing the most recent and improved designs. The exhibits will include, amongst other things, machinery in motion, scientific instruments and applications of electricity.

Damage from Lightning.—A severe thunderstorm passed over the south-west of Devonshire at midday on Saturday. One of the pinnacles of Walkhampton Church, on the fringe of Dartmoor, was struck by lightning, and serious damage was done. ——The parish church of Cowden, Kent, was seriously damaged by lightning on Tuesday evening. The spire was struck, and the shock passing downwards carried away a large portion of the steeple. Some damage was caused to the hammer of the great bell and to the interior of the church.

Cowles Patents in Germany.—The Cowles patents for the manufacture of aluminium alloys by electricity have been upheld by the German courts. This decision is the outcome of an action for the revocation of these patents, which was recently brought forward by Dr. H. Kunheim, of Berlin, who relied on the so-called anticipations of Sir W. Thomson (1879), Benzon (1858), Faure (1882 and 1883), and John Calvert (1856). The Heroult process, which is employed at Oerlikon, is not, so we are informed, patented in Germany.

North Staffordshire Mining Institute.—A meeting of the members of this Institute was held on Monday evening at Stoke-on-Trent, Mr. James Heath presiding. A Paper was read by Mr. T. M. Winstanly Wallis on "Electricity as Applied to Coal and other Mines, &c." In reply to an expression of disappointment that the Paper had not dealt with electricity as a motive power, Mr. Wallis said the transmission of electricity as a motive power was quite as large a subject as its use for lighting. A vote of thanks was accorded to Mr. Wallis for his Paper.

Brighton.—The Gas Committee of the Brighton Town Council recently received a letter from Viscount Torrington, Chairman of "Crompton and Co., Limited," inquiring whether the Committee would be willing to consider a scheme for the lighting of Brighton by electricity. It was resolved that Viscount Torrington be informed that the Gas Committee are not at present in a position to entertain a proposal for the supply of electricity in the borough. At a subsequent meeting of the Town Council the proceedings of the Committee were unanimously confirmed.

The Lighting of the Queen's Yacht.—The *Portsmouth Times* says:—"The electric light has completely spoiled the attractiveness of the Royal yachts as floating palaces; hence the Queen's determination not to sleep on board the "Victoria and Albert" in setting out from Cherbourg. When Her Majesty remained on board for a whole night at Portsmouth it was impossible to sleep in consequence of the horrible din kept up by the machinery, and though various improvements were effected on the yacht's return to this port the machinery is anything but perfect yet." Somebody should be hung.

Electric Fire Alarm System at the British Museum.—A complete system of electric alarms has been fitted at the British Museum by H. Dale and Co., of Ludgate-hill. Pulls with special indicators are arranged in various parts of the building in communication with the firemen's room and with the front hall of the building. Upon any alarm being given not only are the police and firemen, by means of an annunciator, informed of the situation from which the alarm is given, but by an automatic relay an alarm is also given at all the entrances and in the principal librarian's house. The arrangements have met with the entire approval of the authorities.

Ipswich.—The introduction of the electric light into the reading room of the Mechanics' Institute at Ipswich was celebrated last week by a conversazione. The installation, which has been put in by Messrs. Laurence, Paris and Scott, of Norwich, under the direction of their local manager, Mr. W. B. Sisling, comprises one 200 candle-power and several 16 candle-power incandescents, the current being supplied from the central station in Carr-street. Amongst the numerous scientific exhibits which were shown on this occasion was one of Edison's perfected phonographs and two half horse-power electric motors made by Messrs. Laurence, Paris and Scott. The light gave universal satisfaction.

Ward's Electric Omnibus.—At the last meeting of the London County Council the Highways Committee reported that they had had before them a letter from the Commissioner of Metropolitan Police stating that an omnibus propelled by electricity occasionally traversed the streets within the hours prohibited for locomotives, and asking whether the Council thought it desirable that any action should be taken in the matter. Having regard to the fact that the Committee understood that the vehicle caused neither noise nor obstruction, they recommended that the Commissioner be informed that in the opinion of the Council there was no necessity, at all events at present, for any action to be taken. The recommendation was adopted.

The Purchase of the Submarine Cables.—The Eastern Telegraph Company have issued the following notice:—"As a certain amount of doubt appears to exist as to the cables which have been taken over by the Government from the 1st inst., I take this opportunity of pointing out to you that the lines which are now being worked by the Government are the cables which connect Great Britain with France, Belgium, Holland, and Germany. Messages intended for India, all places beyond India, Egypt, South Africa, Turkey, Greece, Gibraltar, Malta, the East and West Coast of Africa, Spain, and Portugal should still be handed in at this Company's stations, or if sent from a postal telegraph station should bear the indication *viâ Eastern*."

The Mix and Genest Microphone.—Many of our readers are no doubt aware that in the Mix and Genest microphone the sound-plate consists of a thin diaphragm of finely-fibred firwood. The acoustic qualities of the material are most excellent, but it absorbs moisture very freely, and is consequently liable to get warped and disturb the adjustment of the carbon contacts. After trying several kinds of varnish without obtaining good results, Messrs Mix and Genest now cover both sides of the sound-plate with a thin plate of mica, which is found to protect the wood very effectively, and if not cemented on to it the mica in no way interferes with its acoustic qualities. This improvement naturally renders this form of microphone very suitable for damp climates.

Edison's New Phonograph.—A large party of the Press were entertained by Colonel Gouraud at lunch on Saturday afternoon at the Gainsborough Gallery, and afterwards to a private view of the latest and most improved form of Edison's phonograph. The new model, weighing only 34lb. including the new pedal motive power, is in marked contrast with Edison's first model, which was also on exhibition, having just arrived in this country, and which weighs over 100lb. The new model can be worked either by pedal or by the electric current. These various machines are now on exhibition at the Gainsborough Gallery, 25, Old Bond-street, and as the phonograph now appears to have emerged from the experimental into the practical stage, it is to be hoped that no time will be lost in perfecting the manufacturing facilities, so that the public may be enabled to benefit by the use of the invention.

Exports of Electrical Apparatus.—The exceptionally favourable features of the trade returns for March, which have been published this week, have been reflected in the shipments of telegraphic wire, &c. It will be remembered that the exports for 1888 were about 36 per cent. less than in 1887, and were 47 per cent. less than in 1886. The value of our exports under this head last month was, however, exceptionally high, and as there had been also a considerable increase in January, the aggregate exports for the quarter ended March 31st are not very far short of the total for the previous twelve months. The following is a comparative monthly statement of exports to the end of last month:—

	1887.	1888.	1889.
January.....	£14,442	..... £41,231	..... £112,230
February ...	44,137	 14,051	 32,086
March	73,300	 32,795	 285,993
The quarter	£131,879	..... £88,077	..... £431,309

The Newcastle-on-Tyne Meeting of the British Association.—The list of officials for the coming meeting of the British Association, which will take place early in September next at Newcastle-on-Tyne, under the presidency of Prof. Flower, F.R.S., has just been arranged. Captain Abney will preside over the Mathematical and Physical Science Section; Sir I. Lowthian Bell, F.R.S., over the Chemical Science Section; Prof. Edgeworth, M.A., F.S.S., over the Economic Science and Statistics Section; and Mr. W. Anderson, M.Inst.C.E., over the Mechanical Science Section. The following are the arrangements for the meeting as far as they have been completed:—The first general meeting will be held on Wednesday, Sept. 11. The succeeding evening there will be a *soirée*; on Friday evening, a discourse on "The Hardening and Tempering of Steel," by Professor Roberts-Austen, F.R.S.; on Monday evening, September 16, another discourse; and on the next evening a *soirée*. Excursions to places of interest in the neighbourhood of Newcastle-on-Tyne—including, of course, the Roman Wall—are being arranged for Saturday, Sept. 14, and Thursday, Sept. 19.

Royal Institution.—The following are the Lecture Arrangements after Easter:—Dr. Jean Paul Richter, three lectures on The Italian Renaissance Painters: their associations, their education, and their employment (with illustrations); Prof. E. Ray Lankester, four lectures on Some Recent Biological Discoveries; Mr. Eadweard Muybridge, of Pennsylvania, two lectures on The Science of Animal Locomotion in its Relation to Design in Art (illustrated by the zoopraxiscope); Prof. Dewar, five experimental lectures on Chemical Affinity; Mr. Joseph Bennett, four lectures on the Origin and Development of Opera in England (with musical illustrations); Prof. W. Knight, of St. Andrews, three lectures on (1) The Classification of the Sciences, Historical and Critical; (2) Idealism and Experience in Philosophy and Literature; (3) Idealism and Experience in Art and Life (the Tyndall Lectures). The Friday Evening Meetings will be resumed on May 3rd, when a discourse will be given by Sir Henry Roscoe, M.P., on Aluminium; succeeding discourses will probably be given by Prof. Dewar, Prof. Silvanus P. Thompson, the Rev. S. J. Perry, Prof. D. Mendeleef, Mr. A. Geikie, Mr. C. V. Boys, and other gentlemen.

Sir R. Rawlinson on the Electric Light and Gas.—At the general meeting of the Commercial Gas Company on the 5th inst., Sir R. Rawlinson (a shareholder) expressed his gratification at the reduction which had been made in the price of the Company's gas—from 2s. 6d. to 2s. 4d. per 1,000 cubic feet—as, he said, a very difficult task was coming before gas directors. At that moment a very important inquiry was taking place in connection with electricity before the Board of Trade as to granting permission for the laying of mains and the introduction of street and domestic supplies. His object in addressing the meeting was to urge the directors to bend their energies to meet the difficulty before them by doing their utmost to making the best possible gas at the lowest possible price. A moiety of the complaints against gas arose from defects in the service or the burners, and if the companies would devote their attention to preventing the extension of such complaints they would be doing much to defeat the opposition which was springing up. He had necessarily had to attend a great deal to electricity, and there was no escaping from the fact that it had to a certain extent established itself. He thought it possible that some wealthy persons might choose to give the electric light the preference over gas, but he was absolutely satisfied that the electric light had no chance of ever coming into competition with gas for street lighting, for the general purposes of illumination, or for the domestic purposes of fire and cooking. He knew from information that had been conveyed to him that in the best and most successful cases of electric lighting for domestic purposes the cost was at least double, and in most cases threefold, what it would be for gas. Gas companies must not in the slightest degree despair because a million or two of capital had been subscribed, grand stations were being built, and millions of lights were being introduced into London. All this should simply put them on their mettle.

Iron Sheathing and Speed in Long Cables.—Mr. A. E. Kennelly writes to the Editor of the New York *Electrical World* on the above subject as follows:—In the application of the duplex system to long submarine cables it is always admitted that the artificial line should be the exact representation of the actual cable in respect to resistance and electrostatic capacity, both singly and jointly considered. That this is, moreover, the true representation of the case is proved by the fact, to which I can personally testify, that there is more than one case on record where the artificial lines having been made with great care as faithful copies of the cables for which they were prepared, were found on application to balance them for duplex immediately with little or no adjustment. Of course this is not the general experience, and much time is sometimes required to adjust an artificial line before balance is obtained, but this is always found to be due to imperfection in the imitation of the cable's resistance and capacity, and the principal must, on due examination, be admitted that a perfect artificial line would be a perfect counterpart of the resistance and capacity in the actual cable, both individually as well as in their mutual relationship. This is equivalent to the assertion that a long cable sheathed with iron may be balanced for duplex by an equally long imaginary cable of precisely similar core, but no iron sheathing. Hence it follows that there is no appreciable effect of electro-magnetic induction, for if it existed it is evident to anyone who has measured electro-magnetic induction, that in order to obtain balance between duplicate, actual, and artificial cables it would be necessary to insert a corresponding amount of electro-magnetic capacity in the latter, or what in this case would be an equivalent resource, to diminish the electrostatic capacity of the artificial line, particularly near its commencement. Hence the acknowledged coincidence in the proportions of resistance and capacity throughout the nearer sections of actual and artificial cables conclusively proves experimentally the results obtained mathematically by Thomson, Heaviside and Charles Hockin, to the effect that the iron sheathing of long cables has no depreciatory influence on their speed of transmission. On the other hand, it is well known that very short cables worked at high speeds when balanced for duplex require less electrostatic capacity than a perfect imitation in their artificial line would demand, and this may perhaps be due to the effect of electro-magnetic capacity from the influence of their sheathings under those conditions of high speed and comparatively small retardation."

EXPERIMENTAL LIGHTNING CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You made a valuable suggestion some time ago (*Electrician*, November 2, 1888, p. 810) that at many telegraph stations abroad it might be possible to set up lightning conductors for experimental purposes, and thus accumulate experience concerning their behaviour more rapidly than by waiting for storms and visiting damaged buildings in this country.

You have asked me to make some suggestions as to how they should be rigged up, and what should be tried; and I should be glad to make such suggestions if they are likely to be any help. Skilled observers, who are frequently favoured with storms, will soon accumulate experience enough to render unnecessary any suggestions from me.

But to begin with it may be useful to draw up a few notes on the subject, and I accordingly transmit herewith a Memorandum which you may see fit to insert in your far-reaching paper.—Yours faithfully, OLIVER J. LODGE.

University College, Liverpool, March 30, 1887.

Memoranda with regard to the Erection of Experimental Lightning Conductors at Telegraph Stations Abroad.

1. It would not be wise to erect anything experimental on an inhabited building, still less on a building utilised for telegraph purposes. A detached shed or a flagstaff is a more suitable support for an experimental rod. A shed offers rather more scope for experimenting than does a flagstaff, though perhaps it is less likely to be struck. There are, however, a few experiments which can properly be made *in the neighbourhood* of an actual lightning conductor, always provided that it be not tampered with in the least. (*See* § 10 *et seq.*)

2. To gain experience as to the advantage or disadvantage of very thick conductors, a couple of conductors might be erected on the same shed or on a pair of adjacent poles:—one a very stout copper rod, the other a quite thin iron wire, even so thin as No. 27.

3. A lightning conductor might be erected on a pole, consisting of various thicknesses of wire in series. Suppose, for instance, iron wire is used. It should be No. 1, or very thick, at the top where the lightning strikes, because that is the place where local melting is almost certain; then it might change to No. 5, No. 8, No. 12, No. 16, No. 18, No. 20, and then once more to No. 5 to take it properly to earth. It would be instructive to find some of these wires melted and not others.

4. An obvious modification of the above experiment is to join copper and iron in series alternately, to use strip in some places instead of wire, and otherwise to vary the circumstances, but always making thoroughly good joints.

5. A distinct conductor might be erected, say of No. 5 iron, with a purposely bad joint, say ¼ inch gap, to see what happens there. At another part of the same conductor there might be an imperfect joint, the parts in contact but not joined properly.

6. Since it is the object to get these conductors struck, rather than to dissipate atmospheric electricity silently, it may be well to terminate them with knobs instead of points.

7. As detectors, to record whether a given rod has been struck or whether a flash has passed in a given direction, one may suggest—

(*a*) A small steel bar or needle placed pointing east and west at right angles to the conductor; to be tested after a storm for magnetism with a compass needle.

(*b*) Some form of lead or tinfoil fuse or cut-out inserted in the length of the rod itself.

(*c*) A branch cut-out adjusted in a tapping circuit, say a bit of wire joined to two points of the conductor a few yards apart, and having included in it an exceedingly fine piece of platinum or other wire to be destroyed by the branch current.

(*d*) A similar branch or tapping circuit, say of No. 16 wire, coiled several times round a quill glass tube containing a sewing needle; to be tested for magnetisation.

(*e*) Some form of registering Cardew or other voltmeter might be similarly connected to two points on the conductor.

(*f*) An Abel fuse or other convenient explosive might be used.

(*g*) A small bulb containing a mixture of hydrogen and oxygen, with a pair of Pt wires close together, would furnish evidence of a very minute spark.

8. To observe side-flashes, a short supplementary conductor, with a detector in its course, could be led from an independent earth to near a point on the conductor a few yards above ground, leaving, say, half an inch gap. A side spark might very well occur across it.

9. Side flashes may also occur to quite insulated conductors—for instance, a rod hung inside the shed on silk or glass or paraffin, with one end near the conductor; only the amount passing in this case, being small, is not so easily detected. A gas leak, or an Abel fuse, is the readiest way of obtaining a record of the passage of a small spark.

10. Near a main conductor—a real one or an experimental one—supplementary short rods might be erected, some earthed, some insulated, and at varying distances from the main conductor. Each of these conductors should have a detector in it, and induced surgings in totally disconnected conductors may then be observed, without any side-flash to them.

11. A horizontal incomplete circuit of wire may have one end connected with the lightning rod and the other end arranged anywhere. Spittings off are likely to occur from this free end, even though it be curved upon itself and brought back close to its beginning.

12. Along the walls of a shed a series of detached conductors, tinfoil strips, or thin wire, may be arranged, with moderate gaps between. They are very likely to spark into one another when a flash occurs, whether the final one of the series be connected to earth or not.

13. A pair of insulated wires arranged close together anywhere near the conductor but quite disconnected from it—one end of one being connected to the ground, and the other end of the other being connected with anything fairly insulated—are very likely to have a spark pass between them when a flash occurs. One way of proving the passage of such a spark is to have a powerful battery permanently joined to the two wires through a cut-out, for the spark will then start an arc.

14. Entirely uninsulated things, such as gas and water pipes, are liable to spark into each other when a flash occurs; and this also may be detected by a sufficiently sensitive recording arrangement, such as a suitably arranged gas leak, or the detonating bulb mentioned in 7 (*g*).

15. In all cases the best possible earth should be made for the experimental conductor, and by frequent testing no loophole should be left for any extraordinary and interesting occurrence to be explained away by the stupid and commonplace exclamation, "bad earth."

16. It seems to me at present of most interest to prove the existence under real lightning circumstances, and with a *perfect* conductor, of electric surgings in all manner of unlikely places—between insulated bodies, between earthed bodies, between bodies at a considerable distance from the disturbance. It will then be desirable to ascertain whether or not such surgings are not more violent when the lightning conductor is a stout rod than when it is a very thin wire, which is deflagrated while acting as a protector.

Manifestly the best protector is one which conducts the flash to earth and which yet sets up least side-flashing and surging. The object of the experiments, therefore, is largely to determine what it is that best satisfies those conditions, and at the same time to note and record all concomitant circumstances of interest. OLIVER LODGE.

REVIEWS.

The Scientific Papers of the late Thomas Andrews M.D., F.R.S., Vice-President and Professor of Chemistry, Queen's College, Belfast. With a Memoir by Profs. P. G. TAIT, M.A., and A. CRUM BROWN, M.D. (London: Macmillan and Co. 1889.)

By his researches on the constitution of ozone, by his discovery of the "critical temperature" and the "continuity" of the gaseous and liquid states, and by the accuracy of his determinations of the heat liberated or absorbed in numerous chemical reactions, Dr. Thomas Andrews has secured an honourable and a permanent place upon the roll of experimental philosophers, and has well deserved the recognition afforded by the publication of a collected edition of his Papers. Dr. Andrews' work—or at least the most original and important part of it—lay chiefly upon the borderland betwixt Chemistry and Physics, and in this department he was one of the very earliest, and during his own life-time one of the most distinguished, workers in our own country. It is, however, somewhat singular to note that the study of electrolytic phenomena, which afford the most conspicuous examples of the interaction of those processes which are distinguished as "physical" or "chemical," engaged but little of Dr. Andrews' attention. In fact, out of the fifty-one Papers in this volume only nine deal with electrical subjects, six out of the nine being, however, concerned with electrolytic or voltaic action.

At the Newcastle meeting of the British Association, in 1838, when Andrews was twenty-five years of age, and had already settled in Belfast as a physician, he read a Paper of some importance on "The Influence of Voltaic Combinations in Chemical Action." In this Paper he showed that with dilute sulphuric acid the effect of the presence of an electro-negative metal upon the rate of solution of pure zinc was to retard the action if the acid was present in any greater proportion than "one atom [molecule] of the dry acid to seven atoms [molecules] of water," but to accelerate it if the solution was more dilute. He also pointed out that seven molecules represents the water of crystallisation of sulphate of zinc. From this and other considerations, Andrews drew the conclusion that "the proper tendency of a voltaic circle is to diminish the chemical action of the solution on the electro-positive metal." Although this view scarcely accords with modern ideas, it is of interest because in supporting it Andrews incidentally shows that he was strongly inclined to believe that every case of "ordinary solution" is fundamentally an electrical phenomenon.

In the same year he published two other memoirs upon this subject, and arrived at a general law, which he stated in the following terms:—

"*The contact of an electro-negative metal increases the ordinary action of an oxy-acid upon an electro-positive metal if the acid is so dilute that the latter becomes oxidised from the decomposition of the water, and retards or arrests that action if the acid is so concentrated that the metal is oxidised from the decomposition of the acid itself.*"

Seventeen years passed away before the appearance of another paper by Dr. Andrews upon an electrical topic. Meanwhile he had been hard at work at the Royal Belfast Academical Institution (where he now occupied the Chair of Chemistry) upon his thermo-chemical investigations, and had also commenced his now classic research upon the constitution of ozone. The Paper just alluded to is entitled "On the Polar Decomposition of Water by Common and Atmospheric Electricity," and is somewhat noteworthy from the fact that it contained an explanation of the cause of the uncertain and discrepant results which had attended the experiments made by Faraday in 1883 (*Experimental Researches*, § 328) upon the decomposition of water by frictional electricity. Dr. Andrews showed that it was only necessary to operate in tubes of small diameter where the evolved gases would quickly dissolve to saturation in the electrolyte in order to obtain perfectly concordant results.

Of his great research on the constitution and properties of ozone we cannot here say anything—although electricity played a prominent part it was rather as an instrument than as a subject of inquiry.

The last electrical Paper is one dated 1875, on "Electro-Magnetic Machines and Recent Improvements in them, by M. Gramme." This was a lecture delivered to the Belfast Natural History and Philosophical Society. It contains a complete analysis of Pacinotti's memoir from *Il Nuovo Cimento*, 1865, with *fac similes* of the three original drawings. This is the best account of Pacinotti's work in the English language that we know of. The Paper exhibits a grasp of the subject which is scarcely less than surprising for the period in question.

How to Make a Dynamo. A Practical Treatise for Amateurs. By ALFRED CROFTS. (London: Crosby Lockwood and Sons, 1889.)

The instructions given in this unpretentious little book are sufficiently clear and explicit to enable any amateur mechanic possessed of average skill and the usual tools to be found in an amateur's workshop to build a practicable dynamo machine. We hope and anticipate that it will be the means of inducing many amateurs to try their hands at the task, and we also hope that the success which they may achieve will induce them to study more deeply the scientific principles which underly the design, about which Mr. Crofts has probably done well in saying very little. We cannot quite agree with the author in his estimate of the extent to which we are indebted to the "amateur" for the progress of electrical science; but since he calls Faraday an amateur, it is probable that our disagreement is a question rather of definition than of fact. The book is one which can be recommended as fulfilling very fairly the purpose for which it has been written.

THE BOARD OF TRADE INQUIRY ON THE LONDON ELECTRIC LIGHTING PROVISIONAL ORDERS.

This Inquiry has been continued at the Westminster Town Hall since our last report. The following gentlemen represented the various parties concerned:—

Mr. Pember, Q.C., Mr. A. K. Loyd, and Mr. J. C. Graham appeared for the London Electric Supply Corporation; Mr. C. A. Cripps for the Metropolitan Electric Supply Company; Mr. Moulton, Q.C., and Mr. R. S. Wright for the Chelsea Electricity Supply Company; Mr. Muirhead for the St. James's and Pall Mall Electric Light Company; Mr. Roger W. Wallace for the Notting Hill Electric Light Company, for the Kensington and Knightsbridge Electric Lighting Company, and for the Westminster Electric Supply Corporation; Mr. Moulton, Q.C., and Dr. Hunter, M.P., for the Electrical Power Storage Company; Mr. G. Prior Goldney (the City Remembrancer) for the City of London; Mr. T. Percy Gunyon (engineer) and two members of the Council for the London County Council; Mr. C. A. Cripps and Mr. F. M. Jenkins for the Strand District Board of Works; Mr. Hopwood (solicitor) for the Holborn District Board of Works; Mr. E. Bayley (clerk) and Mr. G. W. Thompson (surveyor) for the St. Olave's District Board of Works; Mr. James Spencer for the Greenwich District Board of Works; Mr. J. H. Horton for the Paddington Vestry; Mr. Hitchins for the St. George's (Hanover-square) Vestry; Mr. Wilkins (clerk) and Mr. W. Jenkins (chairman of the Lighting Committee) for the St. James's (Westminster) Vestry; Mr. Webster Murnane (clerk) for the St. Martin's-in-the-Fields Vestry; Mr. T. Eccleston Gibb (clerk) and Prof. Robinson, C.E., for the St. Pancras Vestry; Mr. Cripps and Mr. Greenwell for the Marylebone Vestry; Mr. H. J. Smith (clerk) for the Lambeth Vestry; Mr. Harrison (solicitor) for the Bermondsey Vestry; Mr. E. Moore (solicitor) for the Great Eastern Railway Company; Messrs. Payne, Son and Pollock (solicitors) for the North London Railway Company.

THURSDAY, APRIL 4TH (*continued*).

After the evidence of the Earl of CRAWFORD and BALCARRES, Mr. S. DE FERRANTI, the chief electrician and engineer of the London Electric Supply Corporation, was next examined by Mr. GRAHAM, and stated that he had had a considerable amount of experience in electrical matters for some years past. About eighteen months ago he worked out a map showing the different proposed districts of supply and the number of lights to be apportioned to each district. The map also showed the position of every distributing station and the number of lights allocated to each. He had also worked the matter out a second time with Mr. Ince, one of the directors of the company, and discussed the subject a number of times with the different directors. The works at Deptford were commenced about a year ago. Excavations covering a space of 200 feet square were made, and in that buildings were erected to contain the plant capable of working up to 40,000 horse-power. They had just completed the erection of two engines, each of 1,500 horse-power. Two larger engines, each of 10,000 horse-power, are now being erected. He had seen one of the engines of 1,500 horse-power running, and believed the second had been running as well. Each of those sets of engines is easily capable of generating electricity for 25,000 lamps of 10 candle-power. In November next there will be a 10,000 horse-power dynamo ready and another of a similar size in December, when the machinery will be capable of an output of 250,000 lamps. The company

Digitized by Google

have also contracted for erecting further plant, which will give, with that already spoken of, a total output of 450,000 lights. He saw nothing remarkable or extraordinary in the size of the engines of the company; in fact, he was rather disappointed that they had not got larger engines, considering the way steamships had increased the size of theirs. The engine of the Grosvenor Gallery had worked up to nearly 900 horse-power indicated. Although the whole capacity of the lamp supply would be 250,000, it was not proposed to work up to more than 150,000, so as to allow a very large margin to facilitate repairs and also to provide an absolute security against failure in the supply to the current. They were going to lay down six mains with concentric conductors between the Deptford generating station and the distributing stations in London—from Deptford to London Bridge. At London Bridge two would go to Cannon-street, two to Blackfriars, and two to Charing Cross. They are carried in cast-iron brackets along the railway. These cast-iron brackets are provided with India-rubber or porcelain supports, on which the cables can be laid. Each main will carry 100,000 10-candle lamps, so that there will be a carrying capacity of 600,000 lights, although it is not intended to work up to that capacity. In the first place, there will be an enormous margin in the mains. Later on it may be found desirable to have less, but it is always proposed to have a considerable margin in the mains. The mains are so arranged that any one of them may be thrown into connection with any other of them at Deptford, so that to have a total failure of lighting there must be a total breakdown of both engines and mains at the same time. There will be two mains at least in each distributing station, supplied from two separate dynamos, so that the supply is in duplicate, and to have a failure of current from the distributing station both the sources would have to fail. If one only failed from any cause, the other would be of ample capacity to supply the whole demand. In the event of a breakdown in the converter the current would be thrown over by a switch to the other supply, and the converter itself will be cut out by its own fuses automatically. The loss of potential in the Deptford trunk mains he calculated to be one-fifth per cent. per mile run. With respect to the insulation between the inner and outer conductors, he had tested the insulating capacity in a number of lengths up to 1,000,000 volts without getting through or injuring insulation in any way; therefore, with the pressure at which it was proposed to work that would give a safety margin of 100 to 1.

In further reply to Mr. GRAHAM, Mr. FERRANTI said the system proposed by his company has been carried out at Nancy (which has 10,000 lights at the present time). It was also used at first on a large scale at the Grosvenor, but the space available was too small for the plant, which is placed on a number of different levels averaging 25ft. below the street. It was almost impossible to ventilate the place, and the greatest troubles arose from that.

In cross-examination by Mr. MOULTON, who appeared for the Chelsea Electricity Supply Company, Mr. FERRANTI thought every detail of the system proposed by his company was special to the London Supply Corporation, and that success depended principally on details. He thought the amount of coal required per day for 100,000 lights would be 200 tons. He was not prepared to say it would take only 20 on the storage system. He was not acquainted with what they took. As to injunctions, they had had a good deal of trouble with them at the Grosvenor. He had never personally stated that the complaints were unfounded. The company had. With regard to the size of the dynamo, he did not think it was a new experiment, insomuch as the design of the dynamo makes it a combination of a lot of small ones. It was twenty times the size of the one at the Grosvenor. The tension of 10,000 volts at which they work is four times the pressure that has been ordinarily used in London. At Nancy all the wires are underground, working at a pressure of 2,400 volts, the same as at the Grosvenor. There had been cases in which the converters leaked from the primary to the secondary; they had been badly made. In the case of such a leak it would not mean bringing a tension of 10,000 or 2,400 volts into the houses, as the use of their automatic cut-out apparatus would prevent that. It works by burning the fuses which supply the house, and the current is absolutely cut off at the consumer's door. Coming back to the question of insulation, the majority of mains at the Grosvenor were overhead, and some trouble had arisen with them. At Nancy there had only been one single fault, which he thought showed that underground wires are better than overhead wires. The underground wires of the Grosvenor are partly under the Park. They are not tapped every few yards, because consecutive houses are not supplied.

Lord CRAWFORD, in reply to Major MARINDIN, said: The wires run from the back of the War Office to Marlborough House, from thence back to the War Office gate to the corner of Spring-gardens. That is one underground main. Our second one runs from Walsingham House, at the north-east corner of the Green Park, and runs along the south side of Piccadilly on Crown property as far as St. George's-place, at the corner of Hyde Park, and thence it crosses into Hyde Park, also on Crown property, runs on to Albert-gate, whence it is laid under the Pavilion-road as far as Sloane-square. Those are our underground mains. They cross Piccadilly by permission of the local authorities.

Mr. FERRANTI: The underground mains are tapped in many places. There were about 280 installations altogether. At Nancy the mains are tapped every few yards.

Friday, April 5th.

Mr. FERRANTI, on being recalled, was further cross-examined by Mr. MOULTON: He said that the conductors were rigid, and were therefore made in lengths. The Edison Company in New York had found some difficulty in connecting rigid mains, but he thought he had got over the difficulty. The mains at Nancy were all concentric. They consisted of stranded core, then insulation, then wire stranded round that again. They proposed to connect to earth at the Deptford end, but to insulate along the line in order not to disturb telephone and telegraph work. They had experimented on the Underground Railway to see whether concentric mains supplying the current put to earth at one end would give a shock, and they could not feel it. In a long main there would be perhaps 100 volts shock if you got to the bare copper; this was only the ordinary pressure in a house. He did not object to the clause in the order for providing testing stations at various points of the mains if they were to be mere boxes in the street, but he objected to paying rent for places where the mains could be tested. At the Grosvenor Gallery the station is under the demand, and the dulness of the lights is due to the want of steam and nothing else. For fairly complete electric lighting about one light per head of the population is a fair allowance, and the present plant would be equal to a population of about 250,000 allowing for lights not used. He did not know whether his company had entered into any arrangement with the Chelsea local authority. He had heard a good deal talked about Chelsea, but personally he did not know of any agreement.

Cross-examined by Mr. SHIRESS WILL, representing the House-to-House Company: The whole success of the scheme rests upon the power to carry the electricity at the tension of 10,000 volts for the distance of seven miles and maintain insulation along the route. As regards the coal question at the Grosvenor, he reckoned that it would take 100 tons of coal a day in the winter time to maintain 100,000 lights of 10 candle-power; that was calculated on working with 10,000 horse-power at 5lb. of coal per horse-power per hour 10 hours a day with non-condensing engines. With the first-class machinery the company proposed to work with at Deptford it would be nothing like that.

Cross-examined by Mr. WALLACE: As the rigid concentric mains were a modern idea he had had no lengthened experience of them, but he had considerable experience with flexible India-rubber concentrics. The distance from Deptford to the Westminster Underground Station would be about seven miles. Up to London Bridge the mains would all be carried together on the wall of the railway. In the event of anything happening to that wall the whole of the area would be in darkness until they had got power to take another route. The company had another route by the London, Brighton, and South Coast Railway, but they must lay one route before they could lay a second. After their orders were right they would bring another set of mains up by the roads. They proposed to cross streets with the rigid concentric mains in the same manner as gas and water-pipes were carried. Where they were laid under the foot-pavement they would be carried as near the surface as possible, as there would be no danger of heavy weights. In crossing the roads no doubt they would dip down.

Cross-examined by Mr. LYTTLETON: The electrical difficulties at the Grosvenor Gallery were due to their very confined position and numerous other disadvantageous circumstances of position. They were twice flooded by a leaky sewer.

Mr. MUIRHEAD, representing the St. James's and Pall Mall Electric Lighting Company, cross-examined the witness as to the advantages of supplying electricity to the St. James's district from Deptford as against local generation.

Cross-examined by Mr. RUSSELL GRIFFITHS: He did not say that every light would run 10 hours out of the 24, but that the running during night and day would be equal to that; but he did not think that applicable to the City. The street lamps, taking fogs and everything into account, would run about 4,000 hours a year. He did not know that there were 3,000 street lamps in the City that would require lighting, but if that were the number it was nothing very frightful. If they were proposed to be 2,000-candle arc lamps he thought it would be excessive for every lamp-post. He thought 600 arc lamps would be sufficient to replace the 3,000 gas lamps existing at present; but it was only an estimate. That would exhaust about 400 horse-power, or about 9,000 of the lights we are able to supply. Up to seven o'clock at night, at which time the great bulk of the people would have cleared out of the City, they would be prepared to supply, publicly and privately, an equivalent of 100,000 ten-candle lights. According to Lord Crawford they had at present applications for 70,000 lights in the City, all of a private character, which would make, with the public lamps, 79,000 lights, besides any further applications that might be made. The proposed system did not necessarily require a transformer in each house—under certain circumstances there might be one to 20 or 30 houses. They could group the lamp-posts by running a separate circuit with the requisite pressure and put the lamps in series, say 20 lamp-posts to a group with one transformer. The transformers would not be in the streets, but at the distributing station, and worked with ordinary wires, which would be in the streets, the same as if the lamps were lighted by the ordinary direct supply. He had heard of the same system being used in America. With reference to the future development of electricity, he would not go so far as to say that electricity as a motive power would throw the use of it for lighting purposes completely into the shade, but the supply for motive power would be a more profitable one commercially, and would be much more in demand. They had not as yet commenced supplying electricity from their Deptford station. Mains are at present being laid across Blackfriars Railway Bridge. They had permission to take them along the Underground Railway, and they would do that. They would supply their present Grosvenor customers from the Deptford mains, Maiden-lane, and the Grosvenor would be a distributing station. He had not worked out the cost of lighting a street lamp under the arc system. He considered that public lighting would be the reverse of important to the Company. It would be commercially better for the Company if they could get what they wanted without doing the public lighting at the price which, as a rule, is proposed.

Cross-examined by Mr. WILKINS, clerk to the St. James's Vestry: There is no motor at present in the market which is applicable to the alternating current, but there is one likely to be in the market. He had tried a small one and tested it, but was not prepared to give any material information at present—it was not yet commercial. He was not going to say how long it would be before they were in the market. He could not say off-hand what proportion the cost of the

Digitized by Google

main bringing the current from Deptford to St. James's would bear to the cost of plant used in generating the current—he had not worked out the percentage. If the cost of the plant for generating the current at Deptford was £200,000, the cost per mile of bringing the current to St. James's would be a matter of proportion. He could not carry every figure in his head, but if Mr. Wilkins would formulate a question so that he could make a calculation on it he would do so.

Mr. WILKINS: I do not think I can formulate the question better than I have done—What is the proportion between the cost of the plant and the cost of the mains for conveying, say 100,000 lights, 10 candle-power for seven miles—that is, to bring it to St. James's.

Mr. FERRANTI said he would take the question down and let Mr. Wilkins have the figures.

[Later in the day the witness in answer to Mr. Wilkins, said that putting the cost of plant at Deptford at 100, the cost of the main would be 7 per cent., practically an inappreciable amount. That included bringing the current from Deptford to the distributing station in St. James's, and would also include the cost of the mains themselves, of the excavations where necessary, and of reinstating the surface.]

Continuing, Mr. FERRANTI said that the saving on coal would be 50 per cent., and that the site at Deptford would be a large saving in many ways on the cost of production. They proposed to give up the Grosvenor Gallery station altogether. Their plant was so much divided at Deptford that it would be impossible for an explosion to blow up the whole of the machinery. They were enormously divided for safety, but they had got no storage station.

Examined by Captain CARDEW: They proposed to work the mains along the railways with a small amount of insulation between them and the earth. The insulation would be at each support, and not continuous. With regard to the test he had made of the insulation with a pressure of 1,000,000 volts, it had been made with a Wimshurst machine, giving over a 12-inch spark.

Re-examined by Mr. GRAHAM: They were perfectly willing to supply any amount of electricity for public lighting purposes—it was purely a question of price. Their object was not to supply motors driven by an alternating current, but to supply electricity and allow the consumer to do what he liked with it. Their objection to the clause relating to testing stations was not with regard to having testings taken, but to having to pay for the ground on which the testing stations are to stand. They were perfectly willing to allow the Board of Trade, or the local people, or anybody else to test so long as the company were not put to the expense of furnishing a room.

Saturday, April 7.

Mr. C. A. CRIPPS, on behalf of the Metropolitan Electric Supply Company (Limited), wished to explain the views of that company with regard to the Provisional Orders they were asking from the Board of Trade. There were two main points which they could easily establish. The first was that the company he represented was in a thoroughly sound financial position, was supported by men of great eminence in financial circles, and, as they had ample capital, if any more were required there would be no difficulty whatever in finding it. The other point was that the system proposed to be adopted by this company was the best and safest, would stand comparison from an economical point of view with any other system, and as regarded safety and convenience to the consumers, it stood in the best position of all. He was not desirous of criticising the views put forward on behalf of the London company, because they did not fear the competition of any other electric company. The capital of the Metropolitan Electric Supply Company was £500,000 in £10 shares. He believed that when the prospectus was issued the amount was subscribed more than twice over, and the number of shareholders was no less than 700. They had come under obligations already to expend £380,000, or any further sum that might be necessary. The directors did not propose to ask for any compulsory powers with regard to the North London Order, the application in respect of which was withdrawn. The first order upon which they asked for decisions was the Mid-London Order, which comprised the City of London and the Liberties, and the following parishes and places in the County of Middlesex:—St. John the Evangelist, Westminster; St. Margaret, Westminster; St. George's, Hanover-square; St. Giles-in-the-Fields; St. George, Bloomsbury; St. Andrew, Holborn-above-Bars; St. George the Martyr; St. Sepulchre, Saffron Hill, Hatton Garden, Ely Rents, and Ely Place; the Liberty of Glasshouse Yard; St. Anne, Soho; St. Paul, Covent Garden; St. John the Baptist; Savoy, or Precinct of the Savoy; St. Mary-le-Strand; St. Clement Danes, and the Liberty of the Rolls, together with the extra-parochial places known as the Charterhouse, Gray's Inn, Lincoln's Inn, Staple's Inn, Furnival's Inn, and the close of the Collegiate Church of St. Peter. The next order to be dealt with was the South London Order, which comprised the following districts: Lambeth, otherwise St. Mary, Lambeth; Christ Church, St. Saviour's (including the Liberty of the Clink); Streatham, otherwise St. Leonard's, Streatham; and Clapham. Then there was the West London Order. As far as Kensington was concerned the company did not ask for a Provisional Order, but they did for Lower Marylebone and Paddington in the West London Provisional Order.

Major MARINDIN: You may strike "St. Mary Abbot, otherwise St. Abbot's, Kensington," out of the schedule.

Mr. CRIPPS: Yes, you may strike that out as well.

Mr. WALLACE, of the Kensington Court Electric Lighting Company, asked Mr. Cripps if he intended to include that portion of St. Margaret's which was attached to Kensington, the outlying portion of St. Margaret's, Westminster.

Major MARINDIN: That is in the Mid-London Order.

Mr. CRIPPS: We propose to have a station at Whitehall with a capacity of 12,000 lights; we have arranged for a station at Sardinia-street with a capacity of 50,000 lights, at Rathbone-place with 24,000 lights, Manchester-square with 50,000 lights, Eccleston-place with 40,000 lights, and Waterloo Bridge with 20,000 lights.

Major MARINDIN: Are all those arranged for?

Mr. CRIPPS replied in the affirmative, and proceeded to state, with reference to the City, that they had purchased a wharf, known as Greenmore Wharf, which gave them a centre capable of and convenient for supplying the City district. This wharf would be able to carry a plant of a capacity of 120,000 lights. The Whitehall station was supplying a very compact district by means of the direct-current system and storage batteries. The reasons which had influenced the Metropolitan Electric Supply Company to bring forward their present scheme would be given in evidence. He must deny the various suggestions that had been made as to the costliness of coal with reference to the various generating centres. As regarded the question of noise, vibration, and smoke, they were in a very sound position indeed. Of course Mr. Ferranti had a natural bias in favour of the large centre which he was constructing down at Deptford, whilst the Metropolitan Electric Supply Company had a bias in favour of their smaller centres. They were not seeking a monopoly of supply; they relied only on their system being the best and most efficient. They were not there in antagonism with regard to other companies who sought for powers over the same districts. He would give evidence how far the opposition of the various companies extended against the Mid-London Order. With regard to the City of London Provisional Order, the local authorities affected were the Metropolitan Board of Works—which was again merely a formal matter—the Wandsworth District Board, the Lambeth Vestry, and the St. Saviour's District Board of Works, whose wishes they were desirous to meet. As to the question of overhead wires, they were satisfied they had no powers. As the question of the time within which a supply should be given had been raised, they proposed eighteen months, which he thought a reasonable limit. He need only now say that if the local authorities or any companies wished to bring forward any matter in reference to the area comprised in the Bill, they would have the same power as if they were asking anew for a Provisional Order.

Mr. WILKINS, Clerk to the St. James's Vestry, asked whether Mr. Cripps would undertake to introduce the necessary amendment in Committee to make the Bill conform to the terms of the Provisional Order granted by the Board of Trade.

Mr. CRIPPS replied in the affirmative, and he added, in reply to Mr. RUSSELL GRIFFITHS, that he was willing to introduce into the Provisional Order of his company the same amendment as regards all the Orders that was introduced into the "London," or an amendment to a similar effect.

Sir JOHN PENDER, who was then called and examined by the Hon. ALFRED LYTTLETON, said he was chairman of the Eastern Telegraph Company, director of other telegraph companies, and chairman of the Metropolitan Supply Company. The authorised capital of the company was £500,000, divided into 50,000 shares of £10 each. In August last 43,900 ordinary shares were applied for, and there were now upwards of 700 shareholders on the register; £3 a share had been called up, giving a total of £131,700. Of this sum £40,211 had been expended in the purchase of the Whitehall station. The Whitehall Company was taken over on promotion by the Metropolitan, which had since acquired working stations at Rathbone-place, and were now erecting stations in Sardinia-street, Manchester-square, Eccleston-place, and Waterloo-place. For this purpose the company would have spent £351,000 out of the £500,000 when the stations were completed, which left a large margin for working expenses and moderate extensions if required. If large extensions became necessary, he had not the least doubt they would be able to obtain a large amount of capital.

Cross-examined by Mr. PEMBER, representing the London Electric Supply Corporation: He did not object to a wholesome competition at all.

By Mr. R. S. WRIGHT: He thought the great object was to obtain for the public the cheapest light it was possible to produce for a fair return. Their present system was one of separate installations. That upon which they meant to make their mainstay was the alternating system. He should not object to two companies competing in one district, as that one which brought most practical knowledge to bear on the subject was likely to be successful. He thought the Board of Trade ought to be the judge how far it was desirable for one, two, or three companies to take possession of one particular district. He would start all over London with the parts that were likely to pay best in each parish. They had powers to increase their capital, but they had got over £100,000 to spare. They could call up half a million if necessary. A million would be sufficient for lighting all the streets in the whole area they went for. They were not in Chelsea parish nor in Kensington.

Cross-examined by Mr. RUSSELL GRIFFITHS: He believed that they had secured ample space to supply the district they had taken up.

By Mr. WILKINS: As soon as they had done their one work efficiently they would turn their attention to power.

Mr. C. A. CRIPPS here stated that the Wandsworth Board did not oppose the scheme, but rather wished to render it every facility.

Re-examined by the Hon. ALFRED LYTTLETON: They did not object to reasonable competition. He believed that very great developments would yet take place in electricity.

Mr. JOHN EDWARD HENRY GORDON, examined by Mr. C. A. CRIPPS, said he was the electrical engineer to the Metropolitan Electric Supply Company, and had charge of the designing and working of the various installations. The Whitehall station was worked on a system of direct current and storage batteries. They used in it Siemens dynamos and Elwell-Parker batteries, and had no difficulty as regarded either noise or smoke or vibration. They had adopted in the rest of the stations the transformer system, which was a perfectly safe one. The work at Sardinia-street station was nearly completed. They were preparing it for 50,000 lights. Into the Rathbone-street station they were putting plant for

Digitized by Google

24,000 lamps. The Manchester-square station would be capable of working and supplying 40,000 lights. The Eccleston-place station at Victoria would accommodate 150,000 lights, and a large number would be placed at Waterloo Wharf. The company were now spending for machinery about £195,000, on buildings about £50,000, on mains from £80,000 to £100,000, giving a total cost of about £370,000. There was nothing experimental in the system they were proposing. They did not reopen the street—which had only a small demand at first—for every thousand lamps that were ordered, but simply went to a testing box and put in a main and drew it through by means of cords.

Cross-examined by Mr. PEMBER: At the Paddington station the consumption of coal was about 12 tons a day throughout the year for 25,000 lights. In all the others it was rather more economical. They had room for the storage of coal at the stations, besides great facilities at Waterloo Wharf. They had six stations at present, but if they were to supply the whole of the district they would probably treble the number.

Cross-examined by Mr. SHIRESS WILL: They desired to adopt the experience of all countries in this matter—American, English, or European.

By Mr. WALLACE: They could supply a two-mile radius from the Eccleston-place station. They calculated that the lights required in the district would be about one per head of the population. They only proposed to light a small proportion of St. Margaret's, Westminster, from that station, and had made no arrangements for the remaining portion as yet. They proposed to connect the houses with the mains by passing the house mains into the openings at the side of the box, and make a proper joint. The mains could be easily drawn backwards and forwards through these openings. To draw out an old main the joint would have to be cut, but that would have to be done anyhow. It would not be necessary to draw out the whole length of a main in which some connection had gone wrong. Faults could be localised by cutting the connection at a junction box on each side, not at the test boxes, pass a new length of main through, and connect it across before cutting the other, so that the only interruption would be just between those two junction boxes. They were now drawing mains under the pavement in a very small way at Whitehall. None of these mains had required repairing; at Paddington they had repaired frequently. At St. George's, Hanover-square, they proposed to use a transformer station. They were supplying the same alternating current as the London Company, and as soon as a suitable meter came upon the market customers could use it.

Mr. WALLACE here said they would like to have an opportunity of visiting the Eccleston-place station.

Witness continuing, said that plant for it had been ordered of Elwell-Parker, Willans and Wilcox—alternating plant. He had no doubt it could be thrown into parallel.

Cross-examined by Mr. MUIRHEAD: If they got orders for power from St. James's they should very quickly supply it. The alternating-current system could not be used with storage batteries.

Cross-examined by Mr. RUSSELL GRIFFITHS: The lid of the junction box did not appear on the pavement—only the lid of the testing box. The whole process of opening a junction box would take about six hours, and could be done at night. He thought they could find room to put a system of tubes through the city; if there was no room for a full-sized junction box they must modify it. He agreed that there was no known commercial motor that could be used with an electric current. He would place mains 12 inches under the pavement, but under a road with heavy traffic deeper. They would have no overhead wires at all. The Greenmore Wharf, Southwark, intended for the City installation, was between one-third and a-half acre in extent. They would use another wharf for coal storage. 1,000 volts would be the extreme pressure, and a plant could be put on the Greenmore Wharf for 100,000 to 150,000 lights. At present he preferred dynamos of about 200 horse-power each; out of each they would get 4,000 lights. He should advise ten such engines to begin with. The transformer would probably be in a fireproof cellar in the house—as to its position they would be glad to take Mr. Heaphy's directions.

Cross-examined by Mr. J. H. HORTON (Paddington Vestry): They had not yet arranged for a station for Paddington. They would be able to work from South Mews, Manchester-square. Witness put up the Paddington Great Western electric light; the objections were chiefly due to dirt; Mr. Justice North decided that there was no vibration. There had been no complaints for two years.

Re-examined by Mr. C. A. CRIPPS: He looked upon the small unit engine as an economy—either they were working at full power or stopped. At Philadelphia there had been a very instructive instance of one station helping another when the Brush Company had a station burned down.

Mr. RUSSELL GRIFFITHS said there was one very important amendment put in that morning. The company proposed, as in the case of the London Company, to amend section 7, sub-section 7c, by these words: "Provided that nothing in this order should authorise the undertakers to place any electric wires underground, along, over, or across any streets without the express consent of the local authority."

Dr. JOHN HOPKINSON, examined by Mr. LYTTLETON, said this was a system of many stations. With regard to the uniformity of distribution of electricity, it would be much more uniform unless you worked on an exceedingly high potential with few machines; its great advantage was that, as the consumption varied, you could vary the number of machines employed during the small hours of the morning and afternoon, and so on. On the Metropolitan Company's plan one might say that it would be impossible that the supply should fail in any district. It was obvious that bringing a main along a line of railway would increase the danger. They had carefully considered the question of adopting 10,000 volts, or the Grosvenor Gallery 2,000 volts, or to go to 2,500, and had come to the conclusion, although there were some advantages of going to the higher potential, that they would be completely counterbalanced by the possible disadvantage of breakdown in the insulation either of transformers or of mains. There were insulation difficulties even with 2,500 volts. The Metropolitan Company proposed to use one transformer only between the machine and the lamps. They only transformed once, and every transformation meant a loss. This system gave a direct supply, the advantage of which over accumulators lay chiefly in cost. He dared say accumulators would run to £30 per horse-power in the maximum amount put in, and they lost 30 per cent. of power.

Cross-examined by Mr. LOYD: The 1,000,000 volts mentioned by Mr. Ferranti he did not consider a sufficient test of insulation. M. Ferranti spoke of a 12-inch spark.

Cross-examined by Mr. WALLACE: He did not object to accumulators for the purpose of supplementing dynamos.

Cross-examined by Mr. RUSSELL GRIFFITHS: The proper arrangement to prevent disturbance to telegraphic and telephonic wires would be whenever there was a current going out there must be one coming back carrying the same currents within something like six inches. There would be no necessity for a re-arrangement of the telegraphic and telephonic wires.

Further cross-examined by Mr. WALLACE, witness said that they proposed to lay special mains between each of the central stations for the purpose of supplying one another. In case of the destruction of a connection by a fire at any one station they could make a connection outside the building.

Dr. FLEMING, re-called, and cross-examined by Mr. MOULTON, said electricity supplied from storage batteries was undoubtedly favourable to a long life in the lamps, but he did not know that there was anything in the alternating current *per se* which should shorten the life of a lamp. Assuming absolutely constant voltage, the one would not give a longer life than the other. As at present used, the transformers probably shortened the life of the lamps. Transformers were liable to fluctuations of voltage. But assuming that the primary E.M.F. is constant, then there is nothing to cause the secondary electromotive force to vary.

Mr. MOULTON: Not if you put on a large number of lamps? If you load the transformer too much the electromotive force would fall.

Witness continued that there was more difficulty with the transformer in getting that absolute uniformity of electromotive force than with the secondary battery. In the United States the Pittsburg transformer installation of 12,000 or 15,000 lamps was the largest. There was no experience of jointing under anything like the high pressure proposed by the London Company.

By Mr. PEMBER: The transformer system had met with as general adoption in the United States as the direct or storage systems. The strain on the lamps might result from overloading batteries. He had had lamps that lived 7,000 to 8,000 hours.

Dr. HOPKINSON, recalled, and cross-examined by Mr. MOULTON: Variation of voltage—putting too high a potential on lamps—prevented them lasting so long. He should not say it was more difficult to secure uniformity of voltage with the transformer than with the storage battery system. With regard to insulation, the joints were the weakest parts. The real practical question was the probability that faultless joints would be made and maintained during a long run. The Metropolitan Company's dynamo would run about 200 to 250 horse-power.

Re-examined by Mr. C. A. CRIPPS: The variations in pressure could be made lighter with the Metropolitan system than with the battery system, because with the battery system you must go by steps in one cell at a time. Supposing 50-volt lamps were being worked, one of those battery cells would give a potential of about two volts, and so your step must be, say, from 49 to 51 volts—that was a very large difference. He should think the variations under the Metropolitan system could be easily kept within 2 per cent. in the house. As to the variation in the mains, it could be reduced to nil.

Mr. ALFRED HENRY WALTON, examined by Mr. LYTTLETON, said he had been manager of the Paddington works since the Great Western took them over. There had been no complaints for two and a-half years. There had been a slight alteration in the construction of the machines to get rid of nuisance; the field-magnets which revolve had pole plates at the extremities, and the fixed coils on the machine were supposed to have one-eighth clearance all round. On one side of the machine they took out the coils, and shortened them on the top sides, so that they gave a quarter of an inch in front at the left-hand side and a quarter of an inch on the back on the right-hand side. By this means the two sets of coils set up a different note, and so misconstrued one another, and the reduction of noise was found to be considerable. They ran 4,000 lamps of 25 candle-power and about 100 arc lamps from that station.

Mr. THOMAS SPENCER, examined by Mr. CRIPPS, said that he was the engineer of the Westinghouse Company, which company had adopted by preference the transformer system. One thousand volt pressure was employed.

Prof. FORBES, examined by Mr. CRIPPS, said that in his opinion the system proposed by the Metropolitan Company was the best that at present could be adopted. It would preserve a high constancy—the loss in the distributing mains between the feeding points would not exceed one-half per cent. The constancy of pressure was better in high tension than in a low-tension direct supply. The question of the transformers as to keeping the pressure constant was a point of the greatest importance. A fall could not be allowed of more than 3 to 4 per cent. between the hours of maximum and minimum supply. The wiring of the houses generally took 2 per cent. of this, the transformer itself would take 1½, bringing it to 3½ per cent., leaving usually 1½ to play with in the mains. The Metropolitan Company, however, having only one transformer, lost that 1½ per cent. only once. Their system was also highly economical. The E.P.S. was a very interesting but a very costly system, almost prohibitive from an economical point of view.

The INSPECTOR stated that he had been asked to visit the works of the London Electric Supply Corporation. The representatives of the Metropolitan, of the Chelsea, and of the St. James's also invited the Inspector to visit their works.

Digitized by Google

The INSPECTOR replied that when he did so it would not be on any scientific point, but merely to get a general idea of their size and site.

The inquiry was then adjourned to Monday.

MONDAY, 8TH APRIL.

Prof. GEORGE FORBES recalled, cross-examined by Mr. MOULTON, said the Metropolitan Company intended to use the transformer system with 1,000 volts pressure, and his preference would be to have each distributing main connected while in action with only one generating source. He had been asked to examine the cost of batteries in many schemes, but had never had one in his own hands as engineer. He had gone into the question of batteries as a source of distribution very carefully quite lately in connection with the proposed lighting at Paddington by the Vestry, but it seemed prohibitive at present. Of course there is a storage of energy in the accumulator system which there is not in the direct supply system. He had seen the transformer system in America, but had never seen it put to earth there. He thought to put the secondaries to earth a very good thing indeed, but he objected most positively to putting the primaries to earth. The system he had seen worked at Berlin was the most economical production of electricity for a central station in the world—that is to say, the combination of engines and dynamos with condensing arrangements, &c. There was less fuel used for the electrical unit given out in the central station than he had ever seen anywhere else. The greatest variation of pressure allowed in the mains at Berlin was 1½ per cent., which was, he thought, a proper regulation, but necessitated enormous expenses for mains.

Cross-examined by Mr. RUSSELL GRIFFITHS: He had had experience of the system now worked at Rome and Milan. At Rome it is altogether alternating—high-tension alternating—at Milan a mixture of three different systems. At Rome the conducting mains are of wire running below the surface. The public and private lighting would be 6,000 or 8,000 lights of 16 candle-power, but it is a new thing, and they are putting down engines as rapidly as they can. The public lighting consists of about 20 or 30 lamps. The biggest engine is of 400 horse-power. The cost of the lighting is pretty high—considerably higher than that spoken of for London. At Milan they have alternating current used for lighting up two large theatres, they have continuous current on the low tension for most of the incandescent lamps and some arc lamps, and they have also the arc lamp distribution over the whole town, lighting the public streets—high-tension continuous current. Nearly the whole of the arc lamps are used with direct current, either on the low-tension system or on the high-tension system, using the same generating stations but separate engines and separate dynamos. The station has 14,000 incandescent lamps of 16 candle-power, and supplying 350 arc lamps in the streets. The arc lamps were what is called 2,000 candle-power—that is about 500. They have been using Edison's rigid mains, jointed, but they have introduced largely wire mains. For the arc lamps, however, and only for the arc lamps, they use overhead wires. Coming back to the general question, if they had to light a large house like Winchester House, with a great number of rooms, it would not be necessary to have more than one transformer under the Metropolitan system in the house. There would be no difficulty whatever with working it with one transformer, but he did not say it would be the best way. He did not like to say what was the greatest load of lamp supply one transformer could safely carry. He did not think any limit had been proved. They had experimented a great deal in America, and the result of their experience was that they do not make transformers larger than 40 lights of 16-candles.

Cross-examined by Mr. MOULTON: He had been asked by the Vestry of Paddington to advise them on the subject of electric lighting. The plan which he was proposing that the Paddington Vestry should adopt was to burn their dustbin refuse in properly designed furnaces to get up steam. The principal difficulty in the way of doing that was that the dust was always coming in during the day and the burning of it would be all during the night. It was most desirable to get some means of burning the refuse both day and night, and this was, he might mention, the principal object that made him determine to put down secondary batteries as the first enlargement of the plant if the plan was gone on with.

Cross-examined by Mr. WILKINS: He did not think any experience had been had with working rigid mains with high tension current, and to work a rigid main, concentric or otherwise, on a high tension would be an experiment. On the low-tension rigid mains the joint was always the weak part, and the difficulty of making a secure joint was enormously increased by the tension of the current. He did not think there was any difficulty which could not be got over in connecting the service main with the house from a rigid main, but the chief question was that of insulation. He would not like to make the connection while there was a high-tension current in it.

Examined by Captain CARDEW: He would have no objection to putting the secondary to earth in the alternating current transformers, and he thought it would assist the safe working. If he had absolute control he thought he could work to a 1½ per cent. variation of pressure. The fact that a concentric main was being used would not increase in any way the danger of making a connection to a house circuit from a distributing main while it was charged—it was not the danger, it was the impossibility. He was aware there were larger transformers in existence than 40-light transformers.

Mr. ALEXANDER SIEMENS, examined by Mr. CRIPPS, stated that he was Vice-President of the Institute of Electrical Engineers, and that he had had large experience as an electrical engineer both abroad and in this country. His experience extended to Berlin, Moscow, Darmstadt, Munich, and Eberfeldt. In Berlin the system now proposed by the Metropolitan Company had been adopted. There were several small stations, comparatively small; they intend putting up a few more, and eventually to connect all of them. At St. Petersburg, which he did not know personally, they had merely a central station with the three-conductor system direct current. The first lighting started from barges on the Neva moored along the quay, but it was now on land in the usual way, near the places where the lights were used. At Moscow the system was the same as at St. Petersburg. Darmstadt is just being put up. There they have got a system of batteries, but they are employed in a totally different way from the E.P.S. system. It is a four-wire system. At Munich there are three conductors. At Eberfeldt there are also three conductors, and it has the peculiarity that all three conductors are in one concentric cable.

Cross-examined by Mr. SHIRESS WILL: In Berlin the installations are very near together—about half a mile apart, or something of that sort. It was in the busiest part of the city where the lights were all required. He did not attach much importance to the talk about noise, vibration, and smoke, because at the Savoy Theatre there was an installation with 1,200 lights, and nobody had heard anything of it at all. In Berlin he did not believe there had been many serious complaints, and the Government was very fatherly there and would have stopped them.

Cross-examined by Mr. RUSSELL GRIFFITHS: He was a member of the firm which lighted part of the City of London—that is, the Poultry, King-street, King William-street, and London Bridge. They lighted it for one year under contract, and were willing to continue it at the same price. There were six large arc lights and about twenty-eight small ones—the six arc lights were continuous arc lights, each with its own main, and the other lights were alternate-current lights in seven series. The mains for both were copper wires insulated with gutta-percha and covered with tape and drawn into iron pipes, partly under the footway and partly in the street. There were connecting boxes which could be used as testing-boxes at each lamp-post.

Examined by Captain CARDEW: With reference to the question of making connection with the mains while charged, one danger would be that of a short-circuit occurring, and thereby perhaps damaging the mains or setting off the fuses, which danger was equally apparent either with high or low tension, and he would never recommend such an operation to be done practically.

Sir WILLIAM THOMSON, examined by Mr. C. A. CRIPPS, said that he was aware of the system which the Metropolitan Company propose for the supply of electricity in London, and he considered that system as good as any other or the best which could be adopted for the supply of London. The system of alternate-currents and transformers was capable, in his opinion, of being used by means of central stations in crowded places. The highest pressure that he had known used in mains was that of the 2,400 volts at the Grosvenor Gallery installation.

Examined by Mr. GRAHAM: He was familiar with the working of the system proposed by the London Company, and had seen the works at Deptford. He thought there was great but not insuperable difficulty in going up from 2,400 volts pressure to 10,000; it was a very great experiment. He thought there would be difficulty with the insulation, but believed it could be practically carried out. He thought there was no more danger from a high potential than there was from a circular saw. Lighting by the direct current system had a long start of the alternating system—more than three years—he had had it himself since 1881.

Cross-examined by Mr. MOULTON: Difficulty had always been found by telegraph engineers in making permanent good joints under ground, but not insuperable difficulty. Defects sometimes did not show themselves at once, but developed gradually, and such defect would be greatly increased by great pressure. The circular saw, although safe in a workshop, might not be a good thing in the nursery, and it was exceedingly important to keep these high pressures as far away from the consumer as possible.

Cross-examined by Mr. SHIRESS WILL: The mains which had been produced here and which he now saw could, in his opinion, be used for 100,000 lights of 10 candle-power.

Major MARINDIN: Without any insulation outside?

Sir WILLIAM THOMSON said he understood the outside sheath would be insulated. They could be used perfectly with the outside sheath laid underground, but it would make a great disturbance in the neighbourhood. The insulation would have to be done at considerable cost. He recognised the propriety of having some reserve producing power.

Cross-examined by Mr. WALLACE: He could not give an opinion as to the tests that had been made of the high pressure spoken of without having seen them. He had not advised the company in the matter, he had simply supplied an electrometer to work up to 80,000 volts. He thought it better to have reserve power under a day's supply, but something to be effective in the case of stoppage—perhaps 12 hours' supply would suffice for a useful storage reserve.

Cross-examined by Mr. RUSSELL GRIFFITHS: He did not anticipate any disturbance to telegraphic or telephonic wires with the outside tube properly insulated. He thought an insulation sufficient for 200 or 300 volts would be more than ample. He had not thought of what material that insulation should be; it depended on how the mains were laid. If they were laid in an iron pipe, and water was not allowed to lodge in it, he did not think that lead would be necessary round the outside.

Examined by Captain CARDEW: He would recommend the earthing at the Deptford end and earthing of the supply wire in every house, one of the two supply low-tension wires in every house. With reference to the minimum amount of insulation at the mains, his opinion was that as long as the total leakage did not amount to sufficient to cause interference with telephones the amount of insulation would be enough; in fact, if there were no telegraphs and no telephones to be considered the main might be laid in the earth without any insulation at all—it would work perfectly well.

Mr. JAMES SPENCER BALFOUR, M.P. (examined by Mr. LYTTLETON) said he was a director of the Metropolitan Electric Supply Corporation. He thought the capital that had been subscribed was amply sufficient for the present purposes, but he contemplated a further extension of the company in the future, and it was so stated in the prospectus. The shareholders took the shares upon that basis. He had been extremely anxious that they should apply in the first instance only for so much capital as was

Digitized by Google

sufficient to obtain a perfectly complete experiment. He was the owner of a considerable amount of property in the south of London, and a great many applications came from that quarter. He anticipated from Streatham and Brixton a large number of applications for the electric light. He did not think there would be any difficulty in getting a large addition to their present capital (£500,000). The original capital was largely over-applied for. If they had sought for a million they would have got it.

Cross-examined by Mr. WALLACE: He had not entered into any agreement with the House-to-House Electric Supply Company, nor was he about to enter into any agreement or working arrangement of any kind. The public subscribed the capital. In the prospectus produced it was stated that they had applied for Parliamentary powers for a Provisional Order. The Provisional Order was not confirmed, but we obtained it.

Mr. MOULTON cross-examined as to statements in the prospectus affecting the supply of electricity in the parishes of St. James, Westminster, and St. Martin's-in-the-Fields.

Cross-examined by Mr. YOUNG, the witness stated that the whole of the £500,000 capital was subscribed, the amount of the commitments of which was £350,000 at present, but all of that was not expended—it was in course of expenditure. Perhaps £100,000 had been actually expended, leaving about £230,000 or £250,000 unexpended out of the commitments. The free capital was about £150,000.

Sir WILLIAM THOMSON said he desired to say that with reference to the answer he gave in which he said that he thought one of the secondary supply wires ought in every case to be connected with the earth, it was an opinion formed after very careful consideration. Now that the pressure was proposed to be very much higher, it would be dangerous to life, or at all events it would produce a very inconvenient shock, if the metal work of the lamps was at any such potential as 1,000 volts difference from the earth. A person standing on a wet floor or a person in the act of turning a water tap might at some time put his hand on some of the lamp fittings and get a shock that might be very considerable. The larger the transformer the larger its electro-static capacity, and the greater would be the amount of the shock. Such an accident as this produces no danger whatever of fire. His proposal was simply to connect one of the supply wires to the water pipes, to let this be done through a resistance of 10,000 ohms, or 5,000 ohms, and the result would be even in case of a dead earth on the supply wire. The greatest amount of current that could pass would be a few milliamperes. The insisting of that proposal would be no inconvenience to anybody, and people would have the satisfaction of knowing that they have only 100 volts potential in their houses.

Mr. EDWARD STOPFORD CLAREMONT, examined by Mr. C. A. CRIPPS, said he was manager of the Metropolitan Electric Supply Company. The machinery that would be used for the various stations would be perfectly noiseless, and there would not be any risk of nuisances arising from noise, smoke, or vibration. The first station is Whitehall Court, a perfectly isolated position, then Sardinia-street, a very low locality at the back of Lincoln's Inn-fields. Rathbone Place has been running for 18 months, and has never been threatened with an injunction. For the Manchester-square station they held a license from the Duke of Portland, authorising its erection. At the last station, Eccleston-place, there are two nuisances already existing, one a chimney, which they propose to utilise, erected 16 years ago, the other the Metropolitan Railway, the vibration from which must be much greater than could possibly be caused by the engines of the station. The estimate for laying down the mains was £1,250 to £1,350 per mile, which included the cost of opening up the streets, cables, and everything required. The number of applications for lamps already received was—Marylebone, 19,720; St. James's, 6,350; St. George's, Hanover-square, 1,370; City, 1,340; St. Martin's, 2,460; and the Strand, 3,140, making a gross total of 44,660. That did not include the lights they are supplying now.

The witness was cross-examined on behalf of the various companies and vestries interested.

Major MARINDIN said he had received intimation that it would be convenient for counsel that the inquiry should proceed on Wednesday and Saturday this week, and on Monday, Tuesday, Wednesday, and Thursday next week, and this was arranged to be done.

WEDNESDAY, APRIL 10.—SIXTH DAY.

Mr. CRIPPS commenced the day's proceedings by reading copious extracts from a draft agreement between the Metropolitan Electric Supply Company and the Strand District Board of Works. He stated that the agreement had not been actually dated; at the present time there was still some formality to be gone through, but he would hand in the undated printed draft as it stood.

Mr. EDWARD STOPFORD CLAREMONT, recalled, in reply to Mr. PEMBER, stated that except as a point of honourable understanding the agreement was of no validity whatever. Its terms differed slightly in some particulars from the Provisional Order.

Mr. BONNOR MAURICE stated that on behalf of the Metropolitan Electric Company he drew up the agreement.

Cross-examined by Mr. PEMBER: He had no doubt if the order was confirmed by Parliament it would be executed. He did not know whether the agreement would be drafted into the order or how that would be, but the effect would be that the agreement would be carried into effect. According to the second schedule of the agreement, the undertakers shall be entitled to charge 6s. 8d. per unit, but shall not be required to supply in any less quantity than two units per quarter. In the order the consumer is bound to take 15 units as a minimum for £5. 10s., and for every unit above that the company may charge him 6s. 8d. per unit. That minimising of the quantity may be a considerable concession, but on the other hand it may result in getting a much larger quantity taken. He could hardly say whether he would like to do a business with many people who only took two units a quarter. He could deal rather with the construction of the agreement than with the policy of it. There is a clause in the agreement that where the supply is "by lamps" the undertaker shall be entitled to charge for each light for a continuous supply at the rate of 30s. per annum, and for an intermittent supply during 18 hours at the rate of 25s. per annum. The only such provision in the order is a clause to the effect that they may charge a sum per lamp. Under the agreement they were put under a penalty of £100 for every default and a further sum of £5 a day during the continuance of such default.

Cross-examined by Mr. HUNTER: We make the concessions in the agreement with the Strand Board of Works, having regard to the peculiar nature of the Strand. We bind ourselves under clause 4 of the agreement to lay down and complete distributing mains within a period of eighteen months from the date of the agreement so far as the streets are coloured green on the map. Supposing a consumer situate half a mile from the nearest available source of supply, he must, before being entitled to a supply, along with others, provide 20 per cent. of the cost of connecting his premises with that supply.

Cross-examined by Mr. RUSSELL GRIFFITHS: Our company admits, as shown by the agreement, that there may be special reasons requiring different conditions for different districts. The amendment in the Provisional Order as to overhead wires is the same as in the London Electricity Supply Company's Order, word for word, but we shall not obtain by it any rights as to overhead wires; it would not give us any rights that we have not now. Taking the case as put, that having the right under the order to lay mains underground, and that the company lighted house A, and across the street lighted house B, they might, under agreement, use overhead wires, because those wires would not be laid under the order. They might supply, partly under their own Provisional Order and partly under their common law right; he did not say they claimed the right, but it seemed possible—it was arguable that they had a right to go overhead. Mr. Claremont, their manager, had said that in narrow streets they might be obliged to run wires overhead.

Cross-examined by Mr. H. C. JONES: They would furnish the Strand district under the agreement from the Sardinia-street station—that station was primarily appropriated to lighting the Strand. The station would be ample to supply also the St. Giles's district, but he believed there were objections to extending the provisions of the agreement to that district. However that was a question of policy which he was not able to answer. He was only there to answer questions with regard to the form of agreement.

Major MARINDIN: I think Mr. Cripps told me there was no objection on the part of the company to extend the agreement to anybody else.

Mr. C. A. CRIPPS: That is so. You may take that as the policy of the company.

Cross-examined by Mr. CRIPPS: He obtained instructions from his directors to negotiate an agreement with the Strand Board upon the lines suggested in a letter written by them dated 23rd November. He was instructed generally to make every effort to meet the views of the Board as far as their requirements seemed reasonable. He would not go so far as to say that the agreement was equivalent to a kind of partnership between the company and the District Board with regard to electric lighting in the district.

Re-examined by Mr. C. A. CRIPPS: As regards the steets coloured green there was no doubt they would have to lay their mains along and supply them; therefore, in submitting to compulsory powers as regards those streets, it was merely in conformity with what he considered would be the necessary course of the company's business. The intention, he believed, was to lay down those mains at once as soon as power was obtained. Outside the green-coloured district they would be bound by a requisition of six owners or occupiers; under the agreement they were to be given for the purpose of laying their mains a space 12 inches wide and 6 inches deep beneath the present surface of the pavement.

Mr. MOULTON, Q.C., in addressing the Inspector on behalf of the Chelsea Electricity Supply Company, said it was not only his own desire but the desire of the representatives of all the Electric Lighting Companies, who propose to give a continuous supply and to do all in their power to shorten the Inquiry, and therefore he would as far as possible open the general case with regard to direct supply, and especially with reference to the use of storage batteries.

Major MARINDIN: Do you mean to say on that point you are speaking for all the companies?

Mr. MOULTON said: For all the companies that propose to use the direct supply, simply so far as he was dealing with the scientific aspects of the question. He was also instructed by the Telephone Company, but he was not going to refer to them except to give notice of the fact and to say that at the end of the inquiry it might be that those clients would wish to put some evidence before the inspector bearing especially upon some of the statements made by the witnesses for the Metropolitan and the London Companies. His clients were of opinion that the steps taken by the Board of Trade in 1883 and 1884—steps taken after very long and patient consideration and examination of the subject—should not be departed from. He did not say that knowledge and experience had not increased—he would be very sorry if that were the case—but the bearing of electrical knowledge on the practical problem with which these electrical orders were intended to deal had only justified, only strengthened the grounds for the conclusions to which the Board of Trade then came. The Act of 1888, which altered the Act of 1882, although not an Act with which in all respects he could sympathise, was certainly a great concession to electric lighting companies in general, and it admitted that the legislation of 1882 was in error in the unfavourable character of the terms it gave to electric lighting undertakings, so far at all events as the period of concession was concerned. The company that he immediately represented at this moment—the Chelsea—was, he thought, the only company which was bold enough to obtain and try to carry out the order under the terms of the 1882 Act; but it had this clause in the model order which was in addition—and a very reasonable addition—that, supposing any general Act was passed

Digitized by Google

a little later making the terms as to length of concession more favourable to electric lighting undertakings, it should have the benefit of it. In September, 1886, it obtained those powers, and, as they had heard, until the 1888 Act was passed it was not able to set to work because it could not get its capital, but as soon as the 1888 Act was passed it obtained its capital and commenced to work. It had been foreshadowed by the evidence that for house-to-house lighting through a district of comparatively small area the direct supply was the cheapest, best, and most convenient form. It was best to the consumer, most easily capable of being made regular and dependable, and the one which was farthest removed from the risk of extinction. The transformer system had, no doubt, an enormous advantage in dealing with a straggling supply. Distance from the generating source—distance between the different distributing centres—was a matter of comparatively little moment. That which it gives to the consumer is far less valuable, the dangers which attend it are far greater, and its liability to immediate extinction is incurable; but the distance between the centres either of distribution or generation is a matter quite a trifle. Therefore all that those who are supporting the transformer system want is power over a large area. Given power over a huge area, what they will do is—occupy those places in which they can give electric light most cheaply, which were the cream of the whole, and in that way whether Parliament gives them a monopoly or not is a matter of very little concern to them. If they can only get possession of the good bits and can work those good bits on the favourable terms that good bits can be worked, it will not be easy to dispossess them from those strongholds by giving competitive powers to companies who would come in on no more favourable terms.

With reference to the price, he said that with even moderate supervision from the Board of Trade, from the local authority, and from the public, no electrical company could make exorbitant profits. They would not dare to do so, because if it did not reduce its price so that its profits were fair there would be a pressure of public opinion and a possibility of punitive competition. What his clients wished and were prepared to do, was the direct supply in an area, and what they were here for was this: that kind of dealing which the Board of Trade had thought fairest to everybody. The companies he represented were prepared to take clauses which would compel them to do their work, and no better clauses could be found than those in the model order. They were prepared to take their orders under the distinct understanding that if they did not do their duty others should be allowed to come in; but what they did say was, leave us time—give each company an area by itself, an area moderate in size that it could do thoroughly—let each company show how well it could perform those duties—at how reasonable a price it could give a good service to the public, but let it do that unhampered. Let it have a fair field to do that, and in a year or two, when these things were no longer in project but in actual working, they would then see what system was the best, and whatever system was the best then the others would have to adopt it or let competitors in.

It was admitted that the direct supply alone was capable of being used with equal advantage for lighting, but with infinitely greater advantage over motive power. What Mr. Ferranti had in his pocket in the way of motors which would work with alternating currents he did not know. Mr. Ferranti declined to take it out of his pocket. He (Mr. Moulton) could not pick Mr. Ferranti's pocket—that was beyond even the privileges of counsel; but nothing was more remarkable than the way in which inventors had solved just *the* problem of the universe that had never been solved before. He heard these things with deep sympathy. He did not say anything against this patent, but he looked on, should he say puppy patents, while still in their puppydom as things certainly not to be invested in. Now with regard to cheapness. The properties that make it so much the best for the public by reason of there being storage in it and connected with it are the very reasons for its being cheaper. The moment you introduce the power of storing electricity the whole of the curves of demand need not be provided for in the generating plant. Whether you supply entirely from storage batteries or not, you can be using stores that have been piled up during the day, and by combining direct supply with storage you can have all your machines working during those hours. You can have all your batteries discharging directly during those hours, and the consequence is you can easily meet every demand.

In conclusion, he submitted that what they were asking was a reasonable extension. They had shown a willingness and a capacity for doing what they undertook to do, and doing it practically in a much shorter time than they originally took for it, and he thought if this order was granted they would be able to give a satisfactory, steady, reliable, and safe supply of electricity under circumstances which would not excite nervousness in the minds of any reasonable householder. He thought therefore that the orders he represented were orders which should have not only the approbation of the Board of Trade, but that they should be supported by their influence.

Mr. ROOKES EVELYN CROMPTON, re-called, examined by Mr. MOULTON, said he was managing director of Crompton and Co., and from 1882 had given great attention to designs for central stations. Had designed and carried out installations at Vienna, Le Mans, and a central station at Kensington, which had all worked with the greatest success. He was of opinion that engines could not be so economically worked with the transformer system as with the direct system. Nothing increased the wear and tear of engines so much as running them lightly loaded for lengthened periods. Certain well-known makers of engines absolutely forbid it—Mr. Willans absolutely forbids his engines to be run with no load. The best unit area for supply he thought would be about half a square mile from each generating station, each generating station supplying four distributing stations if they could be easily obtained. The cost of carrying a main sufficient for the distribution of about half a square mile for 2,000 yards—that would be the average distance from a wharf site—would be about £5,000, added on to the capital charge.

The Inquiry was adjourned to Saturday next.

OBITUARY.

J. W. FULLER.

It is with great regret we have to record the death of Mr. J. W. Fuller, on the 8th instant, after a long and painful illness, at the comparatively early age of 46. Mr. Fuller's connection with telegraphy dates from a very early period, he having been connected with various telegraph companies for over thirty years, twenty-five of which were spent in the service of submarine cable companies. He joined the Electric and International Telegraph Company soon after its formation, and proceeded afterwards to one of the Mediterranean companies' stations at Benghazi.

On the formation of the Eastern Extension Company he was appointed General Manager at Singapore, and actively superintended the establishment and working of that Company's stations in the Far East. On his return from Singapore in 1874, he was engaged as traffic manager in The Direct United States Cable Company, then being established, and he there organised the traffic and staff arrangements. When that Company passed under the chairmanship of Sir John Pender, Mr. Fuller, in addition to his former duties, was made the Secretary of the Company. In this position he was actively engaged until in the early part of 1887 illness necessitated his retirement. He was a member of the Society of Telegraph-Engineers and Electricians. On behalf of the Direct Cable Company he attended both the London and Berlin Telegraph Conferences. His genial manner and obliging disposition won for him many friends who will regret the premature termination of an active and promising career.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, April 12th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "Electrical Measuring Instruments: Their Properties and Calibration." By SAMUEL JOYCE, jun., Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Iridescent Crystals." By the Right Hon. Lord RAYLEIGH, M.A., F.R.S.

SATURDAY, April 13th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Experimental Optics (Polarisation: Wave Theory)." By the Right Hon. Lord RAYLEIGH, M.A., F.R.S.

PHYSICAL SOCIETY.

3 p.m. "A Lecture Experiment Illustrating the Effect of Heat on the Magnetic Susceptibility of Nickel," and "An Experiment Showing an Effect of Light on Magnetism." By SHELFORD BIDWELL, F.R.S. "On the Dark Flash seen in some Lightning Photographs." By G. M. WHIPPLE. "On Quartz as an Insulator." By C. V. BOYS, F.R.S. "On a Refraction Goniometer." By A. P. TROTTER. "Apparatus to Illustrate Crystal Forms." By Prof. R. J. ANDREWS, M.D.

MONDAY, April 15th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture V., 4. "Instruments for the Measurement of Radiant Heat." By C. V. BOYS, F.R.S.

TUESDAY, April 16th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Discussion on "Armour for Ships." By Sir NATHANIEL BARNABY, K.C.B.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture. "Electric Tram-cars." By Dr. J. A. FLEMING.

WEDNESDAY, April 17th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting. Papers to be read "On the Deaths Caused by Lightning in England and Wales from 1852 to 1880." By ROBERT LAWSON, F.R.Met.Soc. "The Diurnal Range of the Barometer in Great Britain and Ireland." By F. C. BAYARD, F.R.Met.Soc. "Note on a Working Model of the Gulf Stream." By A. W. CLAYDEN, F.R.Met.Soc.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 4 p.m.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and now makes over 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

CONTENTS OF THE CURRENT NUMBER.

"THE ELECTRICAL WORLD" IN THE UNITED KINGDOM.

Arrangements have been made by which "The Electrical World" of New York *can be obtained from* "The Electrician" *Office, 1, Salisbury-court, Fleet-street, London, E.C.*

The Rate of Subscription (payable in advance), is **£1 1s. 0d.** *per annum.*

Single Copies of "The Electrical World" *can also be obtained,* **price 6d. each.**

GOOD FRIDAY NOTICE.

In Good Friday week "THE ELECTRICIAN" will be published on Thursday morning (April 18th), instead of on Friday (April 19th).

Correspondence, Business Notices and Advertisements for this issue must reach the Publishing Office, 1, SALISBURY-COURT, LONDON, E.C., not later than Wednesday morning.

NATURE ON "PRACTICAL MEN AND ELECTRICAL UNITS."

When, at the Bath meeting of the British Association, six months ago, the respective merits of the "practical man" and of the devotee of pure science became the theme of a somewhat unseemly and wholly profitless controversy, we ventured to remark that practical men were not entitled on every occasion to assume superior airs or invariably to speak of the mere theorist in tones of pitying contempt. To this opinion we still hold, but circumstances have now arisen in which it seems to be equally our duty to maintain that when a journal which exclusively represents the school of "pure science" discusses the status of the men who (to use its own words) "fulfil the useful function of putting together machines [*i.e.*, dynamos] they do not understand," the mood of intellectual scorn is after all equally inappropriate. Before entering further upon the argument we must briefly explain the causes which have given rise to this outburst of *Nature*. It appears (for we know absolutely nothing of the matter save what we find in the article before us) that a gentleman "who calls himself a practical man," and who is further described as "representing an important firm" of electrical engineers, recently went down into the provinces, and there addressed the members of an Institute "connected with one of

Digitized by Google

the most important of our national industries." This being the case, we can scarcely be far wrong if we surmise that his errand was really of a commercial character. It is, in fact, clear enough, from the quotations made by our contemporary, that the object of the expedition was not to instruct the members of the Institute in the science of electricity, but to induce them to employ electrical machinery in the industry with which they were associated. With this laudable purpose—however derogatory in the eyes of our critic—the speaker very reasonably laid stress upon the ease with which his auditors might learn what little it was necessary to know in order to deal in ordinary practice with electrical machinery. He told them how, by the aid of an ammeter and a voltmeter, electrical energy might be measured and expressed in units with which they were already familiar. But this is more than our captious critic can stand. "Do the supporters of the practical man," he asks, "think that this easy measurement, this simple connection, came by accident?"—an interrogation which is very little to the point, and seems to us to border upon the absurd.

We are nevertheless bound to admit that our practical man did not altogether succeed in handling his electrical units so as to be at once simple and accurate; in fact, he more than once blundered into inaccuracies of expression which we have not the slightest inclination to excuse. Here we must abandon him to the tender mercies of his critic, whose denunciations are of a wholly remorseless character. To talk of "watts per minute," or to state that "one watt is equal to 4·4 foot-pounds," are solecisms for which we can only express surprise and regret that an electrician should have been guilty. We may, however, remark that to the man whose proper sphere is in the drawing-office or the testing-room, the task of presenting electrical questions to an audience almost wholly ignorant of the subject, and yet deeply interested in its commercial possibilities, can scarcely be esteemed an easy one; in fact, it demands qualifications of a very special order. Had our friend—whoever he may chance to be—been aware that his effort would achieve the distinction of a lengthy review in the columns of *Nature*, he would probably have been a little more careful with his electrical units. But, as we have already said, for his carelessness he deserves rebuke. We are willing, and indeed anxious, to endorse our contemporary's dictum that, "if men are to be 'practical' and nothing else they must at all events be accurate. If they are to use formulæ which they do not understand, they must at all events know how to use them correctly."

But our readers will scarcely fail to notice in the words just quoted—and this is why we deem it necessary to take up the cudgels in defence—that our contemporary conveys the opinion that electrical engineers (and here the reference is more particularly to those engaged in the design of dynamos and motors), *as a class*, are practical "and nothing else," and are accustomed to use formulæ which they do not understand. This is a suggestion which is still more unmistakable in the remainder of the article, and it is one which we wholly repudiate. Our acquaintance with the class referred to—and it must be remembered that the class is a limited one—is probably both more extended and more intimate than that of our contemporary, and we have no hesitation in asserting that from a purely scientific standpoint their opinions are, *as a class*, entitled to the fullest and most respectful consideration. In intellectual calibre, and in the possession of a genuine regard for and a *scientific* interest in their profession, these men will bear comparison with any similar class in this or any other country. These assertions would, we are quite certain, be borne out by the opinion of those gentlemen of professorial dignity who in London come most in contact with them, and who by the way, never exhibit that tone of superior virtue which is so prominent in the article in question.

The reason which chiefly seems to have led the critic into the mistaken notion that electrical engineers are a set o unmitigated Philistines arises from the interpretation which he chooses to put upon a passage in the address referred to—certainly not altogether a happy one—to the effect that "we do not want to know what electricity is but what it will do." The critic takes it for granted that this observation affords a clue t the attitude of electrical engineers in general towards pure science. As a matter of fact, we unhesitatingly deny that it does anything of the sort. We are, moreover, strongly inclined to believe that its originator never intended any such interpretation to be put upon his words. Remembering the circumstances under which they were spoken, it is equally natural to suppose that the phrase quoted was nothing more than a rhetorical way of expressing the fact that for the purpose immediately in view it was not necessary for his audience to enter upon a study of electrical theory; they need not trouble themselves with the inquiry what electricity is, it would be sufficient if they became acquainted with "what it will do." Thus this supposed confession of a brutal utilitarianism sublimes into a mere commonplace of commercial life.

As a matter of fact, we believe that the antagonism betwixt the exponents of theory and of practice is confined to a far more limited number of disputants on either side than a perusal of our contemporary's article would lead one to imagine. The controversy which broke out six months ago had, we thought and hoped, already died away, and we are sorry that our contemporary should—on the very slender basis which we have indicated—have thought proper to fan the smouldering embers. As a matter of fact, in London circles at any rate, the leading men on either side are too well acquainted with one another, and they have too much good sense, to be at all anxious for the continuance of a controversy which is equally barren and factitious. At the same time, we felt that we could not allow to pass uncontradicted so gross a misrepresentation of the views of a class of men of which the profession has every reason to be proud.

THE FRITSCHE "WHEEL" DYNAMO.

The dynamo which we illustrate below has been brought out by Messrs. Fritsche and Pischon, of Berlin, as a low-speed multipolar machine, and some description of it has already appeared in our Berlin correspondent's letter of February 25. Most if not all such dynamos are really only several separate machines—as many as there are pairs of poles—joined in parallel, and to obtain the same E.M.F. as in a similar double pole machine the peripheral speed must be about the same. In the Fritsche winding, however many pairs of poles there are there is only one circuit in the armature—one, that is, in the same sense as there is one only in the ordinary Gramme ring or Siemens drum. The effect of all the poles is therefore obtained in series, and the speed is proportionately low.

In his patent specification (one of the most readable we have ever come across), Herr Fritsche gives the whole evolution of the winding, which we may here shortly reproduce. He first takes an ordinary Siemens drum, and flattens it out (Fig. 1)—a proceeding, *en passant*, which makes it much clearer than the ordinary perspective drawing given in text-books, and which future writers might do well to follow.

The shaded portions represent the pole-pieces; the straight lines, both full and dotted, the active wire on the surface of the drum. The idle cross-wires at the back end of the armature may then be represented by the diagonal lines at the top, while the connections to the commutator segments are at I., II., &c. The wires in the figure are all numbered, so that the circuit may be easily traced.

Digitized by Google

Herr Fritsche now removes the parallelogram A B C D, representing the active wire in the Siemens winding, and brings the remaining upper and lower "idle" wires together, alters the shape of the pole pieces, and obtains the winding shown

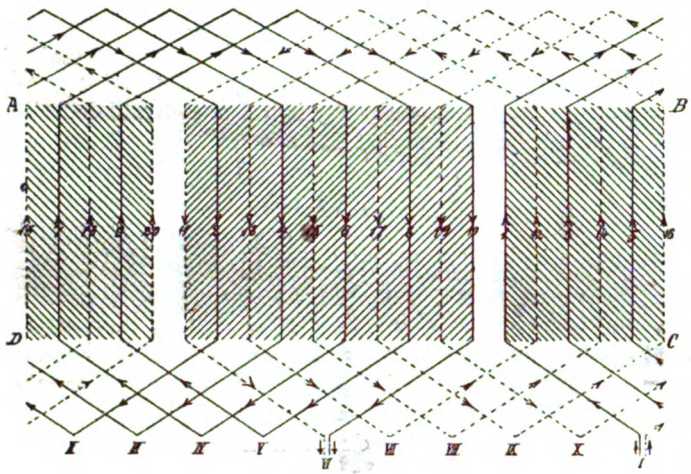

Fig. 1.

in Fig 2. In this form, however, the bends in the middle of each conductor would make it unpractical mechanically. Looking, however, at the point where the bends in two conductors are superposed, *e.g.*, 1 and 12, 3 and 14, 5 and 16, etc., we find, taking the first pair, that the current in the lower part of 12 is in the same direction as in the upper part of 1, while that in the lower part of 1 is in the same as in the upper part of 12; therefore, instead of bending each wire back on itself we can cut it and join the lower end of 12 to the upper end of 1, and *vice versâ*, and the same with all the other pairs. We thus arrive at the winding shown in Fig. 3, giving the equivalent of a Siemens winding composed only of what *was* the idle wire, and built up of plain, perfectly straight strips (except that there is a slight circular bend to form a round drum). For this form

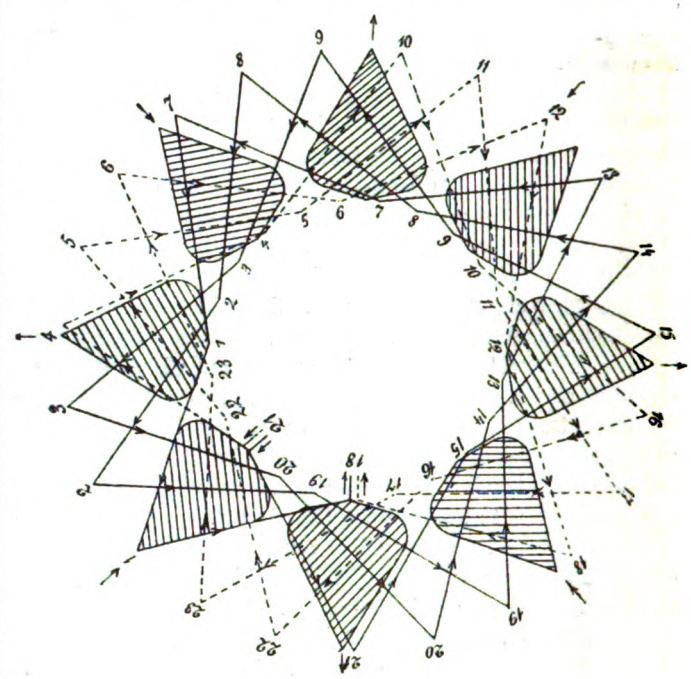

Fig. 6.

Herr Fritsche suggests the name of "wave-winding." Let us now apply these two windings to multipolar machines. Fig. 2 will extend to Fig. 4, giving no greater E.M.F. (*cæteris paribus*) than Fig. 1, and will require as many pairs of brushes as there are pairs of poles. Fig. 3, on the other hand, when extended to Fig. 5, still requires only one pair of brushes, however many pairs of poles there are, and the E.M.F. is increased in the same proportion.

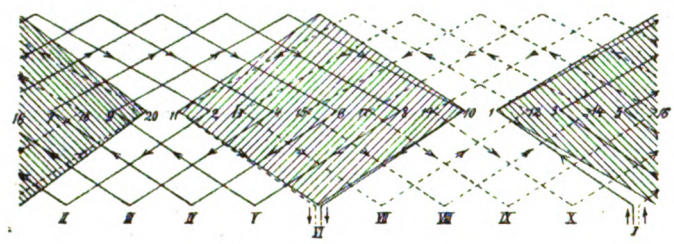

Fig. 2.

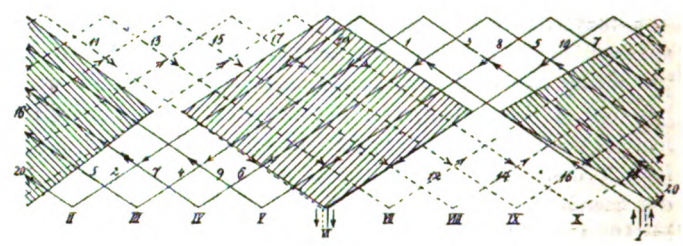

Fig. 3.

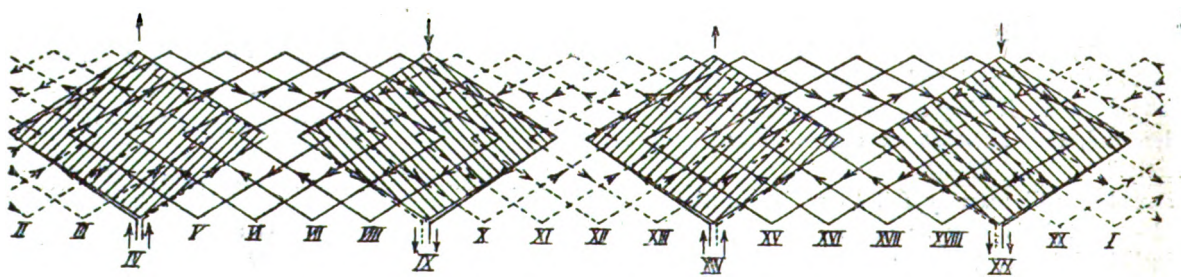

Fig. 4.

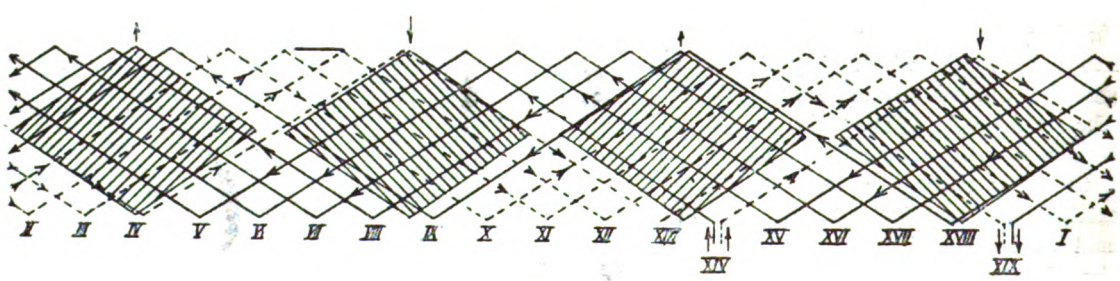

Fig. 5.

Digitized by Google

We have so far considered the winding as if it were a flat strip to be rolled up into a drum, but there is obviously no reason why the two ends should not be bent round *in the plane of the paper* until they touch, thus giving the disc armature shown in Fig. 6.

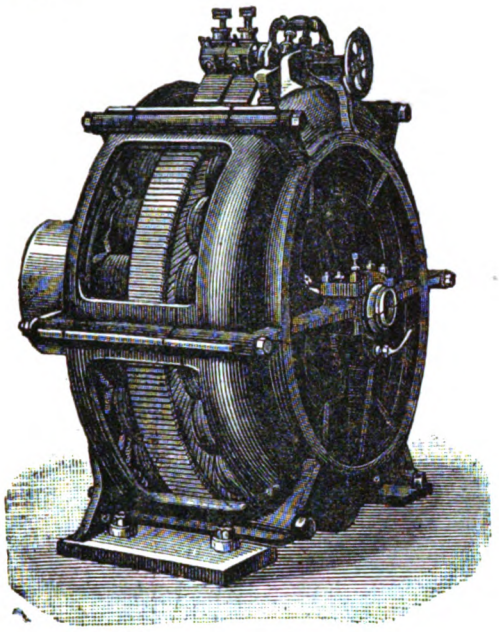

FIG. 7.

The drum form has, we are informed, been used with good results, but at the present moment the disc armature is of more interest as exemplified in a type of machine recently put in the market. This is shown in Figs. 7 and 8, and quite apart from the winding is remarkable from the fact that the armature is formed of wrought iron bars, with air insulation only, there being no core of any kind. The inventor claims that, owing to the use of iron instead of copper allowing greater heating, and to the very perfect ventilation due to the absence of all solid insulation, a large current density can be used—in fact, that the armature could be run almost red hot. A low magnetic resistance is also attained, and Foucault currents are

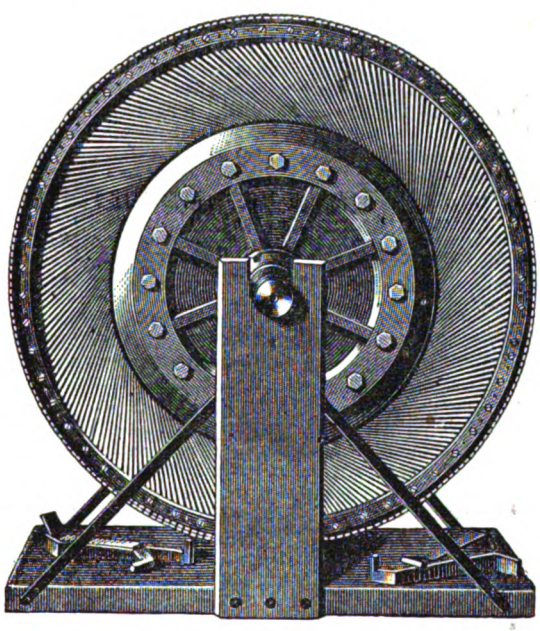

FIG. 8.

diminished. But while all this may be admitted, yet, when it is considered how small a proportion the cost of the copper in the armature of a good modern dynamo bears to the total cost of the machine, we take leave to doubt whether the employment of iron for the armature conductor is strictly defensible.

The following table gives some further details as to the machines actually constructed :—

Speed.	Current.	Output.	Armature Resistance.	Weight, cwt.	Weight, cwt. per h.p.
180	50	5,500	—	28	3·8
160	85	9,400	·06	42	3·3
160	130	14,300	·04	56	2·9
140	200	22,000	·025	76	2·6
140	330	26,300	·0138	102	2·9
140	540	59,400	—	140	1·75

E.M.F. in all sizes, 110 volts.

We may remind our readers that in our issue of March 29 (p. 602) Messrs. Jehl and Rupp claimed to be the inventors of a similar winding. We have some recollection of having received a description of the machine referred to by them about twelve months ago, and probably our reason for withholding it from publication was that the machine did not appear to have been actually built at the time.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

SECTION III.—MAGNETIC FIELDS OF COILS AND SOLENOIDS.

(*Continued from page 596.*)

149. *Intensity of Field at the Centre of a Solenoid.*—In the treatment of this subject there is involved the use of a branch of mathematics not frequently understood either by those who are commencing their electrical studies or even by old and tried practitioners. But while it is very serviceable to be able to sum up a series of extremely small quantities by the usual mathematical process, it is very much more important to have a common-sense view of what has to be done to attain the result aimed at. It is a cause of disappointment and dismay to many students who have been carefully following up a subject to find themselves, after much labour spent in trying to understand it, handicapped by a mathematical process which is said to attain the desired result, but of which they do not comprehend the meaning. The said mathematical treatment would be quite out of place in these Letters, and if the result were put down accordingly without any explanation of the process by which it is arrived at, the reader would be no better off than before. Hence, it seems desirable to steer a middle course between these two extremes. But the task so proposed has in it somewhat of the difficulty experienced by Ulysses on his voyage from Troy, when, to save his men from the grasp of Scylla, he ran the risk of getting wrecked in the whirlpools of Charybdis ; and it is possible that in trying to avoid one alternative we may in some way run foul of the other. The student will find, however, that if he gets a common-sense view even of the *manner* of arriving at the result, or clears up any previously foggy ideas on the subject, he will certainly have scored another point to the good.

To fix our ideas, let us suppose a solenoid six centimetres long, wound with five layers of wire, 40 turns to the layer, and therefore making in all 200 complete turns. Let the depth of the winding—that is, the thickness of the five layers, be half a centimetre, and the reel on which the coil is wound 3·5 centimetres diameter ; this makes the *mean* radius (r) of the coil two centimetres. Suppose that a current of three amperes is passed through the wire, it is evident that it circulates 200 times round the bobbin, and the total current passing round the bobbin is therefore $3 \times 200 = 600$ amperes. Although each turn is really in series with the rest, yet if we look at a section lengthwise through the coil the ends of the wires appear like so many separate conductors, each in "parallel" or "multiple arc" with the rest, and the total current is therefore the sum of the currents carried by each conductor, viz., 3×200; or we may regard the winding as equal to $200 \times 3 = 600$ ampere-turns, which may be replaced, without in any way altering the

Digitized by Google

field, by a single turn, occupying the same volume as the 200 turns, and carrying 600 amperes. This is the most convenient, and, at the same time, the most accurate way of looking at the action of a solenoid. We shall therefore think only of the total current circulating uniformly *once* round the bobbin and occupying the same space as the winding. Or, putting the same thing in a general form, to which any figures may be applied, let n be the number of turns of wire on the solenoid, and C the current in C.-G.-S. units passed through the wire. Then we can regard this as a current of Cn C.-G.-S. units making one turn round the bobbin. Now it is convenient to consider this single turn or belt of current as divided up into a large number of thin rings of current, because then we can calculate the field produced at the required point by each narrow ring. In short, the expression which was derived in paragraph 145, viz. :—

$$2\pi C \frac{r^2}{R^3},$$

for finding the field in C.-G.-S. units produced at any point on the axis of a ring of mean radius r centimetres, assumes that the current C is in the exact centre of the wire forming the ring. To make this clear, suppose we take a ring of *wire* and a wide flat *ribbon* of copper, which, when bent round, makes a single turn of cylindrical shape, of the same diameter as the ring. Now, although the same current be passed through the single turn of wire and the single cylindrical turn, the field produced by each at their respective centres is not the same; for in the wire the current is concentrated into a narrow space *immediately surrounding* the point where it is required to determine the field, whereas in the wide cylindrical coil the current is spread over the whole cylinder, and it is therefore only a small portion of the current which flows *immediately over* the centre point. Further, it is obvious that the remaining portions of the current which are flowing round parts of the cylinder further and further away from the centre must have less effect in producing field there than would be the case if the whole current was massed together right over the central point, as in a ring of wire. And therefore we can only apply the above expression to rings of wire or coils of several turns whose *breadth* is very small compared to their *diameter*. But it follows that the field produced by the entire cylindrical coil can be estimated by considering its current as divided up into a large number of very narrow, thin rings, the field due to each of which at the required point can be calculated by the above expression, and the several results for each ring so obtained finally added together. This gives the field produced at any required point on the axis due to the current *in every part* of such a cylinder, and is, in fact, the way in which the total field due to a solenoid is calculated. For the whole coil of wire of a solenoid is cylindrical in shape, and we have seen that it may be considered as one turn occupying the same volume, which is therefore also cylindrical.

(To be continued.)

REPORT TO THE VESTRY OF PADDINGTON ON THE ELECTRIC LIGHTING OF THE PARISH.

BY PROF. GEO. FORBES, F.R.S., M.INST.C.E., M.INST.E.E.

Gentlemen,—The report on the electric lighting of Paddington, which I now have the honour to submit, is divided into three parts, each of which I shall consider separately. These are :—

1. The advisability or non-advisability of the Vestry undertaking the lighting of the district themselves.
2. The best scheme for generating and distributing the electric current if the Vestry undertake the work.
3. The cost of laying down and working electric lighting plant.

1.—The Advisability or Non-Advisability of the Vestry Undertaking the Lighting of the District themselves.

. . . Whether the Vestry undertake the public supply of electric light, or leave it in the hands of one or more supply companies, one point ought to be insisted upon, namely, that the whole of the streets should be lighted by means of arc lamps. If this is done, the streets will have at least thirty times as much light as at present, leading to increased comfort, safety, cleanliness, and morality, assisting the police, and raising the rateable value of the parish immediately by attracting new residents.

The question remains whether it is more wise for the Vestry to undertake the work themselves or to put it in the hands of one or more supply companies. On this point public opinion has been divided, but it seems nearly certain that the granting of a concession to one company may cause an objectionable monopoly, whilst the introduction of competition will probably lead to disaster among some of the competitors and disappointment among the consumers. Furthermore, the work might be done by others in a manner that would not be approved by the Vestry. To take one example, neither the local authorities nor the Board of Trade have sufficient power to prevent a supply company from using overhead wires. The Board of Trade are actually going so far as to virtually give their authorisation to such overhead wires, and the Vestry must recognise the fact that overhead wires will be largely used by any supply company to whom they may grant a concession. If it be considered undesirable to have overhead wires, this is a strong argument in favour of the Vestry undertaking the work themselves. Another advantage gained by the Vestry doing the work themselves is, that the conduits laid for the conductors might be used for introducing a very complete system of fire alarms and signals.

The question, however, which must decide this point is largely one of cost. Will the street lighting cost the parish less when in their own hands, and will the charges for private lighting in this case be also less? There can be only one answer to this question, which is discussed in the third section of this report. The street lighting will cost very little more than at present if undertaken by the Vestry, and the private lighting will be done by them for charges about one-half of those proposed by electric lighting companies. . . .

The reason why the Vestry can so far benefit the residents of the parish are obvious. A supply company has usually to spend more in obtaining sites, carrying out works, breaking up streets, &c., than a Vestry; they must pay, besides the working expenses, a dividend; directors' fees must be paid; the whole capital must be paid back in 42 years, after which time they lose the goodwill in the business they have created. With a Vestry or other local authority this is not so, and the expenses of erecting and managing works are far less. . . . Finally, as will be seen from the second part of this report, a Vestry can economise fuel by burning the dustbin refuse of the parish, which it now costs over £1,000 a year to get rid of. In view of these facts, I have no hesitation in recommending the Vestry to undertake the electric lighting of the parish themselves.

2.—The Best Scheme for Generating and Distributing the Electric Current if the Vestry Undertake the Work.

I do not advise the Vestry to enter upon this work unless they thoroughly realise that this is no experiment, and that they are prepared to undertake to supply all the electric light required in the parish. . . .

The work which has to be done divides itself naturally into two parts :—(1) Street lighting, to be paid for by the rates; and (2) private lighting, to be paid for by the consumers. The parish will be divided into two districts, A and B, of which A is the richer and B the poorer portion. The district A will be dealt with immediately *in toto;* the district B will be added in due course.

I have taken into consideration every practical system of distribution which might be adopted, and I have no hesitation in arriving at the conclusion that the following plan is the most satisfactory which can be adopted for lighting the parish of Paddington, limiting my remarks in the meantime to district A.

Street Lamps.—There will be about 400 arc lamps, carrying a current of 9 or 10 amperes, giving a light which is spoken of in the trade as being 2,000 candle-power. The lamp-posts will be 30ft. high, and separated to a distance of about 80 yards. Additional illumination may be given in special cases, and the position of lamps has been so chosen that there will not be a single dark slum or mews in the whole district. The illumination may be looked upon as fully thirty times as good as the present illumination by gas. The lamps will be connected to eight circuits, 50 lamps being in series on each circuit. The lamps will be supplied with a current continuous in direction. Ultimately half the lamps will be put out at midnight. At present all are to be lighted together. A tracing is shown, which may be placed over the map of the district, showing the proposed arrangement of mains. The object aimed at has been to arrange the eight circuits so as to overlap. Thus, if ever it should chance that one circuit was defective, the streets would not be in darkness. This tracing is liable to modifications when it is actually decided to proceed with the work.

Conductors.—The conductors will consist of copper wire, insulated with vulcanised India-rubber and covered with protecting braid, and will at present be drawn though cast-iron gas-pipes, placed, where possible, under the foot-pavement, and in other cases under the kerb or in the roadway. Some of the long-feeding conductors may be carried along either of the railways if the necessary permission is obtained.

Private Lighting.—The private lighting, whether by incandescent lamps or by arc lamps, will be carried out by means of an alternating current combined with converters. By this means high-pressure currents can be carried through thin and comparatively cheap conductors over the whole district, and converted into the low-pressure currents required for private lighting by means of the induction apparatus called converters. Each of the street lamp-posts will have a space at its base, closed by a door. No joints of any kind will be allowed in the conductors, except inside these receptacles in the lamp-posts. When a house asks for the electric light branch conductors will be led from the nearest lamp-post into the house, where a converter will be placed. The mains laid down in accordance with this scheme will be supplied with current by conductors, called feeders, from the central station, the number of these feeders and their points of attachment being increased as the demand for light increases. The mains over this district will be sub-divided into sections, each supplied from a

Digitized by Google

separate feeder. It will be noticed that the private mains are totally independent of the street-lamp mains. Conduits being once laid, the mains for private lighting can be drawn in as required. Owing to this separation of the private and street-lamp mains the services of lamplighters are dispensed with, as the lamps can be lighted up or put out from the central station.

The Central Station.—The best site for the central station is in the neighbourhood of the Vestry's dust wharf, but no difficulty would be experienced if another site were preferred. Provision must be made at the outset for the supply of a maximum current for 10,000 incandescent lamps of 16 candle-power, or the equivalent in lamps of different candle-power, consuming about 1,000 horse-power, besides about 400 horse-power for the arc lamps. The size of the dynamos required will depend upon the practice of the manufacturer whose tender is to be accepted. The engines to be adopted will probably be compound tandem engines, working at high pressure. Condensing will not be adopted in the first instance, because, until the consumption of lights is very large the fuel will be an unimportant item and the cost of procuring condensing water will be excessive. But later on it will probably be desirable to sink artesian wells for this purpose.

Boilers and Furnaces.—A great economy can be effected by using the dustbin refuse of the parish as fuel. In connection with this part of the subject I have inspected numerous places where refuse is so burnt, but I do not find that the plans hitherto adopted are generally suitable for the present purpose. In many of these it is the practice to put on the furnaces everything which it is desired to get rid of, including animal matter in the form of sewage and also diseased meat and carcases of animals generally. This produces bad odours, and in the present case only the dustbin refuse should be burnt. I have examined this refuse in the parish of Paddington, and find it largely composed of coal, cinder, wood, and other materials which burn well. With ordinary care in firing no black smoke is ever seen. In cases where boilers have been used they are generally looked upon merely as an adjunct to the apparatus for destroying refuse, and are not efficient in producing steam from the heat of combustion, 150lb. of fuel being required in many cases to generate the steam for one horse-power for one hour. I have, however, prepared a design for combining a suitable furnace with a boiler in such a manner as to produce an efficient result, where we may certainly expect to obtain in actual practice one horse-power for one hour from the consumption of 15lb. of fuel. [A tracing of the proposed arrangement is appended to the report.]

If this system be adopted there will be a residue, consisting of a clinker or a slag, whose weight is about one-fourth of the total weight of fuel used; and a proper means of disposing of this must be prepared. At Bolton this clinker is pounded and mixed with lime and made into mortar, which is sold at a considerable profit. The Vestry of Paddington might dispose of a large quantity of their clinker in this way. At Southampton the clinker is pounded up and mixed with cement and made into paving slabs, which have a life of at least six years, and which are used by the Corporation for the paving of footways, thereby introducing a great economy. The Paddington Vestry may well adopt this plan on a very large scale. In the same way conduits for the electric light conductors may be made, which will be extremely suitable for the extension of the Vestry's electric lighting works.

Future Additions.—Although I have said that 10,000 incandescent lamps of 16-candle power, or the equivalent current, is enough to start upon, the fact must be realized that the cost of production and the cost charged to consumers will be reduced by an addition to this number. The reason of this is that the conduits sufficient for the larger number must be laid and other expenses incurred in the first instance, so that, to increase the number of 16 candle-power incandescent lamps to 25,000 with the same kind of machinery would not require a proportionate increase of capital. The first increase, however, to the capacity of the central station will be effected by establishing secondary batteries in the bath-houses owned by the Vestry, situated in the centre of a district requiring a large amount of light. These batteries will be charged during the day-time by the same machines which during the night are supplying the arc lamps. This will give a very large increase of output from the machinery with very little additional expense.

Preliminary Work.—If the Vestry resolves to undertake the work themselves immediate action must be taken to prepare the necessary drawings and specifications previous to asking for tenders. A trial of the plan proposed for utilising town refuse must also be made, for which purpose a small boiler and furnace should be put down, which might be utilised in preliminary trials for disposing of the refuse clinker.

3.—The Cost of Laying Down and Working Electric Lighting Plant.

In preparing the following estimates for the guidance of the Vestry I have considered it necessary to separate the street lamps from the private lighting. The estimates of capital expenditure include everything that is necessary for starting the works in a thoroughly satisfactory condition, giving current to 400 arc lamps in the streets and maximum current equal to that required for 10,000 incandescent lamps of 16 candle-power. This amount is found in actual experience to meet the requirements of 15,000 lamps actually put in place, only two-thirds being ever in use simultaneously. The estimates include cost of laying conduits over the whole district, so that with a few days' notice the supply can be given to any customer in the whole district.

The general result arrived at is that the total capital expenditure amounts to £95,540, of which £38,500 is spent on arc lighting in the streets and £55,040 on the private lighting, and £2,000 on mortar mills and paving-slab works. The annual expenditure on arc lights, including contingencies, is £5,096; the depreciation account is £1,898; and the annual payment of interest at 3½ per cent. and capital to be repaid in thirty years is £2,050; total, £9,044. The charges which would be made by a supply company for this lighting with underground conduits would be from £12,000 to £15,000. The annual expenditure on private lights, including contingencies, is £3,320; the depreciation account is £2,600; and the annual payment of interest at 3½ per cent. and capital to be repaid in 30 years is £2,970; total, £9,390.

There is some difficulty in examining the figures with respect to the arc lighting with a view to comparison with the present cost. In the first place, I have been unable to separate out the street lighting account in past years for the district A apart from the whole parish. And again, the plan proposed of disposing of the dustbin refuse introduces a great saving, which ought to go to the credit of the public department represented by the street arc lamps. In the annual report of the Vestry for the year ending March 25, 1888, the expenses of lighting the streets amount to £7,993, less a balance in hand of £749, giving a total cost £7,244; of this probably one-half, say £3,600, is spent upon the district which I call district A. The cost of sifting the dustbin refuse and removing it, less the receipts from sales of materials, is not easy to arrive at. It appears that a sum of £3,871 is spent in wages, sifting, haulage, canal dues, loading and unloading, of which £1,594 is for wages in collecting the dust—the difference is a saving of £2,277; but there are further expenses which it is difficult to apportion, but certainly there will be a saving of £168 for the engineer and assistant and stoker, making a total saving in the dusting department of £2,445, from which must be deducted the present profits from sales of materials, amounting to £1,065, leaving a total saving of £1,380. This, added to the £3,600 now spent in lighting, gives £4,980 as an approximate estimate of present expenses which will be abolished when the streets are lighted by electricity. I believe, however, that if the accounts could be properly sifted it would be found that this estimate is somewhat under the mark.

The private lighting is much more easy to deal with, though even here there is some uncertainty. Most of the district is of a residential character, and if we wish to be on the safe side it is not safe to allow for each lamp an average period of lighting of more than two hours a day, let us say 700 hours per annum. If the customers are charged by meter, with a rental for the meter of 14 shillings per annum, with an average of 50 lamps to the house, and at the rate of 4½d. per Board of Trade unit, the receipts will amount to £9,507. The total expenditure of all kinds, including depreciation and also annual payment of interest and capital, is £9,320, leaving a balance of £187. The cost at which supply companies in the metropolis are proposing to charge customers is from 7½d. to 1s. per Board of Trade unit, with a considerable supplementary annual charge generally added.

By the time that the 15,000 lights provided for as above are all taken up the demand for electric lighting will be pretty well established in the district, and it may be well to point out, that with an additional expenditure of about £40,000, involving total annual charges of about £5,000, in addition to the above estimate, the total number of lamps supplied would be increased from 15,000 to 37,500, increasing the income in the proportion of 5 to 2, which would reduce the charge which would have to be made to less than 4d. per Board of Trade unit.

I have not prepared detailed estimates of the expenses and receipts in connection with disposal of the clinker by converting it into mortar, paving-stones, &c., not having been able, so far, to obtain accurate data as to the prices which will be obtainable. I have, however, no doubt that this part of the business will add considerably to the profits of the undertaking, while the additional expenditure on account of capital is certainly not likely to exceed £2,000.

In preparing the estimate supplied herewith I have assumed that the work of laying the conduits is to be undertaken by the Vestry itself. If let out to contract the cost would be somewhat in excess of the estimate now arrived at.

It has been already stated that the cost of street lighting by electric arc lamps will be but little in excess of the present cost of street lighting. The estimates show a difference of £4,064. I feel confident that this, however, means no addition to the rates, but rather the contrary, because residents will be attracted and the ratable value of the parish sensibly increased by the great improvement proposed in the lighting of the streets.

The following is a statement of capital, expenditure, and cost of working:—

Preliminary Estimates.

Capital Expenditure on Street Arc Lamps.

Proportion of buildings, foundations, smoke-shaft, &c.	£5,000
Boilers, furnaces, brickwork setting, small engine, fan, pumps, steam-pipes, &c.	2,500
Ten dynamos for arcs (two spare), five engines (one spare), 400 arc lamps, belts, switches, instruments, and accessories	14,000
Tools, &c.	250
One-third of 25 miles conduit	5,450
Thirty miles cable, with laying and jointing	3,000
Four hundred lamp-posts and fixing	4,800
Engineering expenses and contingencies	3,500
Total for street lamps	£38,500

Annual Cost of Street Arc Lamps.

Depreciation on boilers, machinery, and lamps	£1,650	
„ cables	150	
„ buildings, &c., and lamp-posts	98	
		£1,898
Proportion of wages and salaries	1,350	
Proportion of rents, taxes, water, oil, waste, and stores	500	
Carbons	2,616	
Contingencies	630	
		5,096
Annual payment, interest and capital		2,050
Total for street lamps		£9,044

Digitized by Google

Present Annual Cost of Street Lighting.

Present cost for street lighting	£3,600
Present extra cost in dealing with refuse	1,380
Total cost at present	£4,980

Capital Expenditure on Private Lighting.
(15,000 16 candle-power lamps.)

Proportion of buildings, foundations, smoke-shaft, &c.	£10,000
Boilers, furnaces, engines, dynamos, and accessories, with traveller, spare machinery, and converters (for supplying a maximum current for 10,000 lamps of 16 candle-power)	23,500
Tools, &c.	750
Three hundred meters	2,100
Two-thirds of 25 miles conduit	10,800
Thirty miles cable, with laying and jointing	3,000
Engineering expenses and contingencies	4,890
Total for private lighting	£55,040

Annual Receipts from Private Lighting.

15,000 lamps of 50 watts each, averaging 700 hours per annum, at 4½d. per Board of Trade unit	9,297
Rent of 300 meters	210
Total for private lighting	£9,507

Annual Cost of Private Lighting.

Depreciation on boilers and machinery	£2,350	
,, buildings	100	
,, cables	150	
		£2,600
Proportion of wages and salaries	2,150	
Proportion of rents, taxes, water, oil, waste, and stores	1,100	
Contingencies	570	
		3,820
Annual payment, interest and capital		2,970
Total for private lighting		£8,390

Extra Capital Expenditure.

Extra capital expenditure on mortar mills works for paving slabs, &c.	£2,000

Total Capital Required for Works Proposed.

Street arc lighting	£38,500
Private lighting	55,040
Mortar mills, &c.	2,000
	£95,540
Estimated cost for a plan the same as above, but supplying 37,500 lamps of 16 candle-power instead of 15,000	£135,540

THE VAN DEPOELE SYSTEM OF ELECTRIC RAILWAY.

FIG. 1.—Van Depoele Electric Railway at Montgomery, Ala.

We give above illustrations of two electric railways run on the Van Depoele Overhead System. The capital city street line at Montgomery, Ala. (Fig. 1), is one of the largest in the world, having over twelve miles of track, with heavy grades varying from one to eight per cent. The equipment consists of ten cars with ten horse-power motors, and four cars with fifteen horse-power motors. The Windsor Electric Railway (Fig. 2) is a cheaply constructed line, running along the bank of the Detriot River between Windsor and Walkerville.

The Van Depoele Electric Company uses single or double overhead wires, or a conduit, according to circumstances. In the case of overhead wires the traveller usually runs on the top of the conductor, although, in some instances, a contact wheel pressing upwards against the conductor is employed. The overhead conductors in some cases are run in a rather novel fashion; poles are placed along the curb on opposite sides of the streets, from opposite poles a cross wire is strung, and from this cross wire is hung the copper conductor running the whole length of the track. Judging from American experience there can be little doubt as to the cheapness and practical efficiency of the overhead system, but it is to be feared that the narrowness of our streets, to say nothing of æsthetic reasons, will greatly hinder its use in this country.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March 30th*, 1889.

It would appear that the storage battery decision which has just been rendered by Judge Coxe in the United States Circuit Court here is practically the first of the kind dealing definitely with storage battery priority in this country, and that it may have an important effect on the future of the industry. The decision results from an action brought by the Electrical Accumulator Company against the Julien Electric Company upon four patents, one to Shaw and Rogers, one to Camille A. Faure, and two to J. W. Swan. The action was for infringement, which the Julien people denied, setting up various pleas of defence. Judge Coxe has taken the trouble to go into the subject in a very thorough and exhaustive manner, and his decision presents an interesting review of the progress of the art. The decision affects directly three patents, the first of the four patents in suit, that to Shaw and Rogers, being withdrawn by

Digitized by Google

the plaintiffs from the litigation, and practically given up. As to the two Swan patents, these were declared invalid, one being on the preparation of plates with perforations, cells, or holes extending through the plate into which the active material is packed, and the other on pretty much the same thing, "the support in the form of a plate with angular or equivalent holes or perforations extending through the same and separated from one another by webs, holes, or partitions of uniform cross-section, the active material being placed in said holes, &c." The first patent, No. 312,599, issued February 17th, 1885, was invalidated on the evidence of Prof. Eaton, of Brooklyn, who showed that as far back as 1881 and 1882 he made plates with perforations, his evidence being corroborated by witnesses who assisted in making the batteries and in punching the holes. The second patent the Court threw out because it held that after the first patent there was absolutely no room for the second. "When a patent has been granted for a plate containing rows of holes, another patent cannot be granted for the same plate containing uniform rows of holes. Neither can there be anything patentable in the mere shape of the holes. A patent for a device containing round holes will preclude a subsequent patent for the same device with square or triangular holes. Especially is this so when the applicant is confronted with his own express declaration that the shape is wholly immaterial."

The debatable ground thus being narrowed down to a consideration of the Faure claims, the Court goes into an elaborate discussion as to their merits, and concludes by recognising Mr. Charles F. Brush, of Cleveland, Ohio, as entitled to be considered the first inventor and patentee in this country of secondary batteries in which the active coating is mechanically applied. The Court says that after the patent, No. 252,002, of January 3rd, 1882, was granted to Faure, interferences were demanded by Brush, and on an investigation into his work they resulted in a decision in Brush's favour at all stages during the progress through the Patent Office. As to his priority on the broad method of applying the active material mechanically, Judge Coxe characterises the language of the Faure specifications as loose and inaccurate, and says that construed under it, therefore, the first claim is anticipated in every form except that in which the active material takes the form of a "paint, paste, or cement." Judge Coxe also declares against the broad sense of the Faure claim of the same patent, in which the grouping of the plates in a series of cells with non-porous partitions between them is described. This method of grouping is held as not being a new combination of familiar elements, but as a combination for which there was precedent and which would occur to anyone versed in the art. Having thus ruled on the claims, the Court has intimated that if all the Faure patent in claim I. be disclaimed except the specific method of applying the coat to the plate by means of "paint, paste, or cement," it will sustain the patent on such a claim. When this has been done the Electrical Accumulator Company will be entitled to an injunction and to an accounting, but in the meantime it has been taxed with the costs, and the Julien people now assert that it is not their practice to employ the active material in such a manner as a paint, paste, or cement, but as a dry powder. It is claimed by the representatives of Brush that this decision, with its narrowing of the Faure claims and the cancelling of the Swan patents, puts the Brush patent in the first place as one which must be recognised as a master patent by the Electric Accumulator Company as well as by others. This being the case, the results will be interesting and important in their bearing on the future of the storage battery.

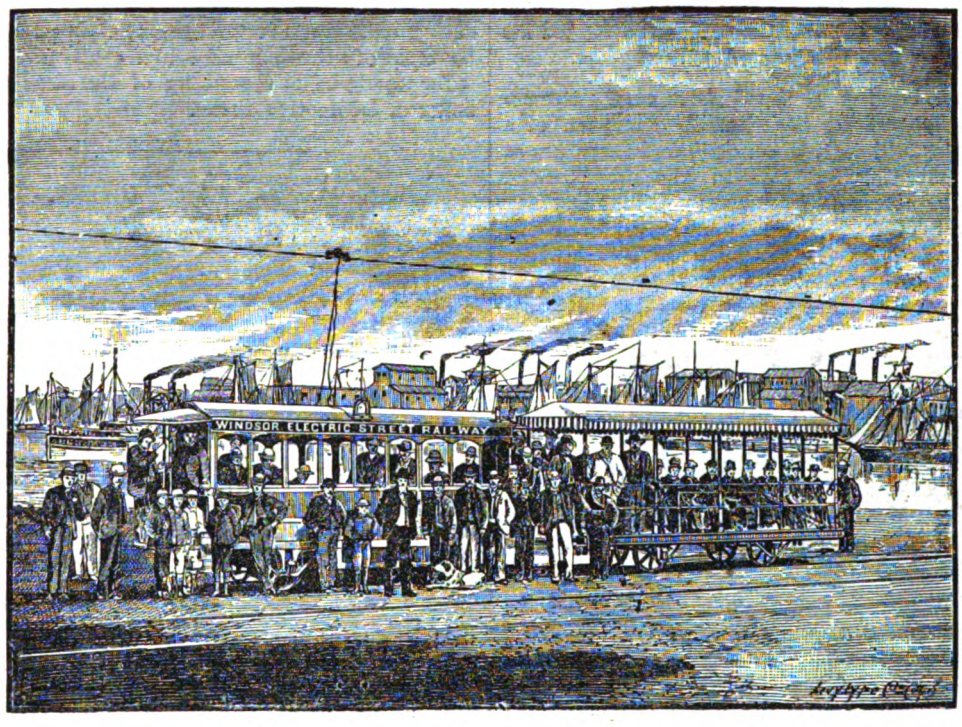

Fig. 2.—Windsor Electric Railway.

Interesting, too, is the fact that the decision thus rendered gives pre-eminence to the work of two American inventors in this field. Other American investigators of the subjects are considered, but their work is not characterised as reaching that degree of practical success which would entitle them to the control of the commercial storage battery. Thus reference is made to Kirchoff's U.S. patent, No. 31,545, in which the coatings of the plates were described as being produced out of and at the expense of the storage battery fluid, and as the gradual and slow result of charging. Reference is also made to the work of Dr. Van der Weyde, who gave evidence as to what he had done fourteen and twenty-five years ago. The doctor well deserves the compliment paid him by the judge, in speaking of him as a man of great learning and research, restless, energetic, and untiring in his labours in the dark and profound

Digitized by Google

mine of science. But the Court pointed out that if such a keen and ingenious man were the author of the great improvement made practical by Faure, it was extraordinary that he should have allowed the secret to languish and perish. Moreover, he doubted whether a man so busy, writing 5,000 articles on scientific subjects in a few years, would have had time to carry out work in this field exhaustively, or if he had done so, would not have recorded it in one of the 5,000 articles. Besides, the doctor during those years took out more than 30 patents, yet he did not consider it of sufficient value to make it the subject of a patent. On these grounds the Court held that it was not right to regard Dr. Van der Weyde's work as a satisfactory anticipation. There can be no doubt that the learned doctor has dabbled in every branch of electrical science and work. Those who attend the meetings of the New York Electrical Society in this city say that nothing is ever brought before that body but Dr. Van der Weyde is ready to recall something of his own exactly like it, and sometimes he produces the identical apparatus, dusty and mouldy and worm-eaten, as though he had just exhumed it from the catacombs of Greenwood. In fact, the doctor is a little like the well-known burgomaster in one of Offenbach's comic operas, who could never resist the inclination in his speeches to get back to the "year one," and who was regarded in consequence by some unkind people as very much of a bore. This is the doctor's only failing, which should be forgiven him, for he is undoubtedly a master of electrical science, and deserves much better luck than has attended his ceaseless and unwearying investigations these fifty years.

As I have said, the bearing of the decision on the storage battery art is important, as we have already some ten or a dozen companies in the field in this country, and there are at least half a dozen promising batteries in the experimental shape. The work to be done, too, grows every day, and it may be safely said that in electrical circles generally here the storage battery is in much greater favour than it was a year ago. The Electrical Accumulator Company announce this week that they have recently made some successful experiments in Philadelphia, and that Brill, of Philadelphia, is completing half a dozen more cars for them. The Julien Company, who regard the decision in an exceedingly jaunty and chipper way, report themselves as very busy, and John Stephenson, the car builder, has just received an order from them for 30 cars to be run on the Julien storage battery system on the Fourth and Madison-avenue line in this city. From Detroit encouraging reports come of the work done there in traction by the Woodward storage battery. Altogether this field promises to be full of activity during the present year.

There is a good deal of talk nowadays about electric light consolidations and combinations, and the *New York World* of Tuesday last has a column and a-half article on the growth of the business, and on a "trust" which it alleges to be near at hand. I would not attempt to deny the statements contained in the article, but if leading companies, in spite of their open and avowed attacks upon each other in the courts, as well as their vigorous statements in the columns of the papers, are actually engaged all the time in making amicable arrangements for a trust or combination, then I can only say that they are remarkably adept at concealing their emotions or assuming sentiments which do not inspire them. According to the *World*, a prominent electrician said to the reporter: "It is an open secret in electrical circles that a trust or a consolidation is practically agreed upon, and it will probably materialise in tangible form as soon as a few more of the pending suits are adjudicated. Each company wants to hold as many trumps as possible before showing its hand. A combination is, however, recognised as a foregone conclusion, but I have not learned whether it is to be a trust, a combination, or an absorption. The Brush Company is the only one making money, and it is in a position to dictate terms; but I understand there is money enough at the back of the Westinghouse Company to buy up all competitors on a reasonable valuation based on their profits and prospects. There has been a tendency towards consolidating electric light and power interests for some time, and there are now really only three or four important parent companies. Consolidation would not only do away with disastrous business rivalry, but would greatly lessen the expense of the service by abolishing and consolidating plants. Electricity is the greatest scientific and commercial factor of the age, and five years hence it will have more than doubled its capital and business if properly encouraged, but the heavy stockholders realise that concessions are necessary if profits are desired. The cut-throat practices have hindered the business, and not only prevented profits but hampered the growth of electric light and power. Although it has not been pushed as other enterprises have it has grown miraculously—has overcome monster obstacles by reason of its own inherent worth—and with a fair chance it is impossible to conceive what it would accomplish." The article closes by stating gravely that there are excellent reasons for believing that the rumours about the trust are well founded, and that the conclusion will be reached during the present year. It will be noted in the quotation I give that the Brush Company is spoken of as the only one making money. You will remember, however, that in my letter last week I gave some figures showing the Thomson-Houston Company to be doing very well. It is also stated that the Edison business is in good shape, and from the way the Westinghouse Company has been absorbing smaller concerns it is to be inferred that they have plenty of money and are quite satisfied with their prospects. The Western Electric Company is also believed to be doing remarkably well, and there are a number of other companies, all of which appear to be very active. Now that the business is down to a manufacturing basis there seems to some observers to be as little reason for trying to throw it all into a combination or trust as there is for trying to do something of the same kind with engine or boiler or locomotive works.

PARIS NOTES.

(FROM OUR CORRESPONDENT.)

April 9th, 1889.

The whole range of the Boulevards, from the Place de la République to the Madeleine, are in the hands of workmen, and at every corner the people passing meet holes of about one metre in diameter and four to six metres deep, joined together by trenches running alongside the footpaths about eighty centimetres wide and one metre deep. These excavations are intended to receive the mains of the companies which have undertaken to light the Boulevards. On account of the great traffic at these points, the companies have not been allowed to open the streets, and at the crossings they have been obliged to tunnel under the branch sewers which join the main sewers on the Boulevards. The general lighting will consist of about 190 arc lights of 10 amperes, worked and installed by the Edison Company, the Marcel-Deprez Company, and the Victor Popp Company. The motive power will be steam for the two first, and compressed air engines in the case of the Popp Company. The lamps will be placed on posts six metres high, erected in the middle of the street, sixty metres apart. Similar work is being carried out at the Place du Carrousel by the Edison Company, and by the Company du Secteur de la Place Clichy in the neighbourhood of the Rue St. Lazare, adjoining the Gare St. Lazare and the Terminus Hotel, where this company will light the shops under the hotel, the street, and the entrances to the station with 15 ampere arc lights manufactured by the Société Alsacienne at Belfort. Numerous private plants are being pushed on in different parts of the city, and the serious efforts which are being made everywhere foreshadow a large display of electric light.

On Wednesday night last, after the meeting of the Société Internationale des Electriciens, the present members of the committee visited the Station du Palais Royal. An explanation of the system was given by M. Fernies. The whole plant reflects great credit on the Edison Company and their chief engineer. Contrary to the Parisian Gas Company, which seems still to believe that the electric light is only a nice toy, the provincial gas companies of Angers, Montauban, and Rouen have been authorised by their shareholder to lay down electrical plants and to offer to their consumers either electricity or gas. The Compagnie du Gaz de Lyon, for whom a station was erected last year by the Société Alsacienne, is more and more satisfied at having taken this step, and sees without regret the daily increase of the demand for electric light.

The provisional installation of 45 1,000 candle-power arcs, which has been put up by the Edison Company on the Champs de Mars, is now completed, and night work will therefore now be possible. The motive plant is divided into two groups, each comprising a Weyber and Richemond portable engine and a dynamo giving

Digitized by Google

223 amperes and 75 volts. I may mention in this connection that M. Bechmann proposes to augment the brilliancy of the illuminated fountains at the Exhibition by the device of projecting the jet through an annular orifice, the beam of light being directed through the centre of the opening. By this means a hollow jet is obtained, and the loss of light due to transmission through the water in the chamber is avoided. It is, however, perhaps a question whether the perpendicular part of the jet will not appear less brilliant than before, since it would seem that less light will find its way through the water until the jet begins to break.

A few days ago the Conseil Municipal suddenly remembered that it had to nominate the "commission technique," consisting of three members, which is to deal with matters relating to the station at the Halles Centrales. Several names were proposed, but no agreement was possible, and after deciding to increase the number of members to five the councillors adjourned. Meanwhile the progress of affairs is arrested. The question of the lighting of the left bank of the Seine has again come before the Conseil Municipal. Four concessions have been asked for, but there seems little likelihood of their being granted, the financial question proving insuperable. It seems probable that the present "concessionaires" will be asked to extend their areas across the Seine, and that the main streets on the far side of the river will be included in the scheme of experimental lighting which the Conseil propose to carry out during the Exhibition period. An electric railway will be commenced shortly between the Porte d'Orleans and Montrouge.

The first scheme which the Government brought forward with regard to the French telephones has been dropped, and a new project is now before the Chamber. The Government requests permission to buy up the Société Générale des Telephones "in toto," purchasing all its instruments, wires, and exchanges. The State will borrow the sum necessary to effect this, the loan to be paid back in ten annual instalments, 40 per cent. of the gross receipts being set aside for this purpose, the remaining 60 per cent. being devoted to the expenses of working and maintenance. The tariff will be considerably reduced, and it is anticipated that the consequent development of the system will enable the loan to be paid off in less than 10 years if so desired. After arranging the question of finance and the case of towns already provided with exchanges, the Bill proceeds to deal with the case of towns as yet unprovided with a telephone system.

At a recent meeting of the Conseil Général de la Seine it was decided to invite tenders for lighting the Asylum at Vaucluse by electricity, and the sum of 142,000fr. was voted. The Asile de Vaucluse is 35 kilometres from Paris, and if the light proves a success there electricity will be gradually introduced into all the establishments controlled by the Conseil Général.

A large central station is in progress at Amiens. Some 5,000 lights have already been applied for, and it is reported that the magnificent cathedral of this town will shortly have the electric light.

CORRESPONDENCE.

DEFLECTION OF AN ELECTRO-MAGNETIC WAVE BY MOTION OF THE MEDIUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: This subject is of interest in connection with theories of Aberration, which requires to be explained electro-magnetically. A plane wave in a non-conducting dielectric is carried on at speed $v=(\mu c)^{-\frac{1}{2}}$, where μ is the inductivity and c the permittivity, and is not altered in any way, according to the rudimentary theory, that is to say, which overlooks dispersion. But if the medium be moving through the ether, it is altered in a manner depending upon the speed of motion and the angle it makes with the undisturbed direction of propagation.

Thus, let $\mathrm{E}_0=\mu v\mathrm{H}_0$ specify a plane wave in a medium at rest, E_0 being the tensor of the electric and H_0 of the magnetic force. Next set the medium in motion with velocity $\mathbf{u}$, changing $\mathbf{E}_0$ to $\mathbf{E}$ and $\mathbf{H}_0$ to $\mathbf{H}$, thus

$$\mathbf{E}=\mathbf{e}+\mathbf{E}_0, \qquad \mathbf{H}=\mathbf{h}+\mathbf{H}_0 \quad . \quad . \quad . \quad . \quad (A)$$

where $\mathbf{e}$ and $\mathbf{h}$ are the auxiliary electric and magnetic forces due to the motion. To find them, we have, first, the electric force due to motion of matter in a magnetic field, or

$$\mathbf{e}=\mu\mathrm{V}\mathbf{u}\mathbf{H} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (B)$$

which formula is well known, and is included in Maxwell's treatise. Next, the magnetic force due to motion in an electric field, or

$$\mathbf{h}=c\mathrm{V}\mathbf{E}\mathbf{u} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (C)$$

This equation, which is as necessary as (B), was, so far as I am at present aware, first given by me in one of the early sections of my "Electro-magnetic Induction and its Propagation," January or February, 1885, and was again considered later on in connection with the "magneto-electric force," which is as necessary as Maxwell's "electro-magnetic force."

We require one more relation, viz., between $\mathbf{E}_0$ and $\mathbf{H}_0$, viz.,

$$\mathbf{H}_0=c\mathrm{V}\mathbf{v}\mathbf{E}_0, \quad . \quad . \quad . \quad . \quad . \quad . \quad (D)$$

the property of a plane wave, due to Maxwell; and we can now fully find the auxiliaries $\mathbf{e}$ and $\mathbf{h}$ in terms of the originals $\mathbf{E}_0$ and $\mathbf{H}_0$. Here $\mathbf{v}$ is the vectorized v of the wave when undisturbed.

In the above V is the symbol of vector product. Thus $\mathrm{V}\mathbf{u}\mathbf{H}$ is the vector perpendicular to $\mathbf{u}$ and to $\mathbf{H}$, whose tensor equals the product of *their* tensors, u and H, into the sine of the angle between their directions. But this is merely used to state the general relations in a compact and intelligible form, instead of with Cartesian abominations.

Instead of taking the general case, it is convenient to divide into three, viz., (1) $\mathbf{u}$ parallel to $\mathbf{v}$; (2) $\mathbf{u}$ parallel to $\mathbf{E}_0$; (3) $\mathbf{u}$ parallel to $\mathbf{H}_0$. By putting the results together we shall obtain the mixed-up general case.

(1) $\mathbf{u}$ parallel to $\mathbf{v}$. Here the medium is moving in the same direction as that of undisturbed propagation, and there is no alteration of direction of either $\mathbf{E}_0$ or $\mathbf{H}_0$, so that it is only necessary to specify the tensors of the auxiliaries $\mathbf{e}$ and $\mathbf{h}$. Thus:—

$$e=-\frac{u}{u+v}\mathrm{E}_0, \qquad h=-\frac{u}{u+v}\mathrm{H}_0 \quad . \quad . \quad (1)$$

If, for example, the medium be moving at half the speed v, and *with* it, the displacement and induction in a given length are spread over a space half as great again as if the medium were at rest, so that their intensities are reduced to two-thirds of the undisturbed values. There is no discontinuity when u is equal to or greater than v.

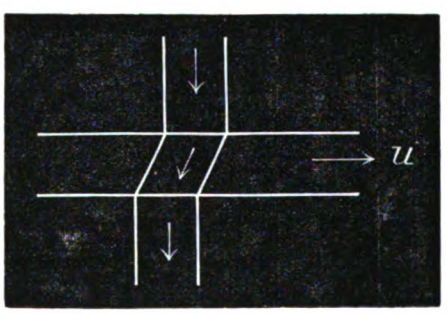

FIG. 1.

But if the medium move the other way there is compression into half the space, so that the intensities are doubled. As it is increased up to v, the compression increases infinitely. After that, with $u>v$, there is reversal of sign of $\mathbf{E}$ and $\mathbf{H}$ as compared with $\mathbf{E}_0$ and $\mathbf{H}_0$.

(2) $\mathbf{u}$ and $\mathbf{E}_0$ parallel. Here $\mathbf{h}_0$ is parallel to $\mathbf{H}_0$, but $\mathbf{e}_0$ is parallel to $\mathbf{v}$. Their tensors are given by

$$e=\frac{uv}{v^2-u^2}\mathrm{E}_0, \qquad h=\frac{u^2}{v^2-u^2}\mathrm{E}_0. \quad . \quad (2)$$

(3) Lastly, $\mathbf{u}$ and $\mathbf{H}_0$ parallel. Now $\mathbf{e}$ is parallel to $\mathbf{E}_0$, whilst $\mathbf{h}$ is parallel to $\mathbf{v}$. Their tensors are

$$e=\frac{u^2}{v^2-u^2}\mathrm{E}_0, \qquad h=\frac{uv}{v^2-u^2}\mathrm{H}_0. \quad . \quad . \quad (3)$$

In either case, (2) or (3), the angle of deflection θ is given by

$$\tan\theta=\frac{uv}{v^2-u^2}; \quad . \quad . \quad . \quad . \quad . \quad (4)$$

consequently the deflection is wholly independent of the plane of polarisation.

Thus, let a slab of (say) glass move in its own plane at speed u, and a plane-wave from the upper medium strike the glass flush. The transmitted rays are deflected as shown in Fig. 1, the deflection being given by the above formula, where,

Digitized by Google

observe, v is the speed in the *glass* when at rest, and u the speed *of* the glass with respect to the external medium.

The above working out of the effect of moving matter on a plane electro-magnetic wave is (if done properly) strictly in accordance with electro-magnetic principles. But it will be observed that Fresnel's result, relating to the alteration in the speed of light produced by moving a transparent medium through which it is passing, is not accounted for. It is said to have been thoroughly confirmed by Michelson. I should like to direct the attention of electro-magneticians to this question, with a view to the discovery of a modification of the above data, or correction of the working, in order to explain Fresnel and Michelson, which *must* be done electro-magnetically. Mr. Glazebrook has made Sir W. Thomson's extraordinary contractile ether do it by an auxiliary hypothesis; surely, then, Maxwell's ether equations could be appropriately modified.—Yours, &c.,

OLIVER HEAVISIDE.

THE WIRING OF HOUSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read Mr. Andrews' Paper on "Wiring Buildings for Electric Light" with very great interest, and am very much inclined to follow his lead. Whilst reading the Paper the thought struck me—why not earth one wire as suggested, connecting to gas and water pipes, and *leave it bare?* You would then save the expense of covering it, and might put the money so saved into extra good quality of insulation for the other (say the negative).

For indoor work, wire very lightly covered with lead might be used, and using the lead sheathing as positive lead, of course connecting a bare copper main to it at frequent intervals, to get the requisite conductivity. This would have the advantage of being waterproof, which I don't see is possessed by Mr. Andrews' armoured cable—I mean that the water is able to get at the insulation—is cheap, and also fulfils Mr. Andrews' object, viz., to convert a "partial short circuit" or "opening circuit" into a "dead short circuit." What do your readers think of this plan?—Yours, &c.,

GEORGE T. PARDOE.

LEGAL INTELLIGENCE.

United Telephone Company v. Siemens Bros. and Co.

In the Chancery Division of the High Court of Justice on Monday last, before Mr. Justice North, the action of the United Telephone Company Limited) v. Siemens Bros. and Co. was disposed of, the parties having come to terms. The action was brought for an injunction to restrain the defendants from infringing the Bell Telephone Patent.

It appeared that the defendants had supplied instruments manufactured by Messrs. Siemens and Halske, of Berlin, to certain persons in this country, and among others to Messrs. Lucas and Aird, on account of the War Department, for use on the proposed Suakin-Berber Railway. This railway was not proceeded with, and the instruments were brought back to this country and were recently put up for sale by the War Department.

The United Telephone Company immediately gave notice that they should take proceedings against any person purchasing and using the instruments, and they subsequently took action against Messrs. Siemens Bros. (Limited) for having imported the instruments from Germany and sold them in this country. The defendants admitted the infringement, but pleaded that they had acted inadvertently, and under these circumstances an injunction was taken by consent, the defendants paying the costs of the action and nominal damages, and the offending instruments (which had been recovered by the defendants from the War Department) being surrendered to the plaintiffs.

Mr. ASTON, Q.C. (with him Mr. Micklem), for the plaintiff, said that minutes of an order had been arranged, which Mr. Higgins, Q.C., for the defendants, had seen. The only point he desired to mention was this. There was an order that the defendants deliver up 16 telephones, which he understood were in the possession of the War Office, and upon these being given up the plaintiff company would be prepared to supply any telephones which the War Office might require.

His LORDSHIP said he did not see what he had to do with this, as the War Office were not parties to the action.

Mr. ASTON said that was so, but the telephones were in their possession.

Mr. HIGGINS said the order was made by consent. The parties were *sui juris*.

His LORDSHIP: I have not looked at the terms. I suppose they are all settled.

Mr. HIGGINS: Yes, my lord.

Durtnall v. Shippey Brothers.

At the Canterbury County Court on Tuesday, before His Honour Judge Selfe, the plaint of Durtnall *v.* Shippey Brothers, electrical engineers, of London, was a claim for wages amounting to £13. 16s. alleged to be due from the defendants as the promoters of the Herne Bay Electric Light Company.

In the course of the case the Judge stated there was no such thing as the Herne Bay Electric Light Company. It had never been formed or registered.

Mr. SHIPPEY said there was a syndicate against whom his firm were going to proceed for their money. He was a member of that syndicate, and would have to pay his share.

In giving judgment, His Honour said there appeared to have been two agreements entered into, one for a joint tenancy of certain premises, between Mr. Hamilton and Mr. Shippey, and the other between the same parties with reference to the work of carrying on the business. He was of opinion that Mr. Shippey and Mr. William Hamilton were partners in the business, and that whatever arrangement was made in March, 1888, on behalf of the Universal Electric Light Company to discontinue their arrangement with Mr. Hamilton, who had engaged the defendant, that arrangement had no effect in putting an end to the partnership.

Judgment was then given in favour of the plaintiff for £9. Defendant applied that judgment might not be entered up at present, with a view to his endeavouring to settle up the Herne Bay business, but the Judge declined to do this on the ground that he did not think a postponement would be of any service.

Cardiff Electric Engineering Company.

At Cardiff County Court on Wednesday, before his Honour Judge Owen, Messrs. Kotyra and Ivicki, described as managers of the Electric Engineering Company, Exchange, Pier-head, Cardiff, were called to answer a judgment summons for £13, which had been taken out against them by Mr. Louis Barnett. Mr. Braham Barnett appeared for the plaintiff.

Mr. KOTYRA only answered to the summons, and stated that he was unable to pay the instalments for which an order had been made, as he only received £1 a week. He did not know anybody connected with the Company except Mr. Watts.

The JUDGE (to the defendant): Mr. Watts is the company, and you and the other defendant are managers at £1 a week. Who pays the rent?

DEFENDANT: Mr. Watts. He pays £10 to £15 a year.

His HONOUR thought defendants could pay the instalments, and made an order committing them to 14 days' imprisonment in default.

THE CARDIFF ELECTRIC ENGINEERING COMANY.—The following, letter, which appeared in a recent issue of the *South Wales Daily News* will be read with some interest:—"Sir: I read in your issue of the 4th inst. a report headed 'Another Mysterious Cardiff Company,' &c. Kindly permit me to explain that there is no mystery connected with the Electric Engineering Company. The firm of Messrs. Kotyra and Ivicki having been twice sold up by the sheriff's officers, I, at the second sale, bought the whole of the plant, and removed it from Castle-street to the Merchants' Exchange, Pier Head Docks, where the business is now carried on as the Electric Engineering Company. Surely there is nothing 'mysterious' about this, as it is well known that thousands of people trade as a company although there may be only one in it. Being myself a plumber, of course I do not pretend to be a judge in electric work, therefore it suits the company's purpose to employ Messrs. Kotyra and Ivicki, whose reputation as skilled artisans is well known, and has for years been established not only in Cardiff but in South Wales and the West of England.—Yours, &c., F. T. WATTS."

COMPANIES' MEETINGS & REPORTS.

The Eastern Extension, Australasia and China Telegraph Company (Limited).

The thirty-first ordinary general meeting of this Company was held on the 10th inst., at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. F. E. Hesse) read the notice calling the meeting and the minutes of the last meeting, which were confirmed by the present meeting and signed by the Chairman as correct.

The CHAIRMAN said: Ladies and gentlemen, before asking you to approve the resolution which I shall submit to you for the adoption of the report, I will, as usual, make a few remarks upon the results of the last year's working. I am sorry that I cannot congratulate you on the brightness of the day, but I hope that the statement I shall place before you will to some extent compensate for the extremely unfavourable weather. The gross receipts for the half-year have amounted to £238,854, against £232,660 for the corresponding period of 1887, showing an increase of £6,194. This amount would have been considerably greater had it not been for the loss of subsidy (£2,744) and traffic, probably an additional £5,000, resulting from the unfortunate interruptions of the Australian section referred to at the last meeting, in addition to which there has been during the half-year the heavy loss of £6,947 on exchange, in consequence of the increased depreciation of the silver currency. The latter, of course, could have been averted by collecting larger payments from the telegraphing public, but as this would be practically increasing the tariffs, the Company do not wish to resort to such a step if it can be avoided. The working expenses for the half-year have been £71,519, against £69,570

Digitized by Google

for the corresponding period of 1887, showing an increase of £1,949, which is mainly due to the cost of repairs to cables being heavier during the past half-year than in 1887. Comparing the figures for the whole year, however, the results are as follows:—Gross receipts in 1888, £478,780, against £451,861 in 1887, showing an increase of £26,919, or over one per cent. on the share capital, whilst the working expenses for the same period show a decrease of £4,900, as follows:—1888, £140,911; 1887, £145,811. One interim dividend of 1¼ per cent. has been paid for the half-year, and it is now proposed to pay another of like amount on 15th inst., making, with the interim dividends for the first half-year, a total dividend of 5 per cent. for the year. It is also proposed to distribute a bonus of 3s. per share, which will make a total payment of 6½ per cent. for 1888. The balance of £66,101 has been carried to the general reserve fund, which now stands at £690,454, as shown by the following figures:—Amount of fund at end of 1887, £620,095; interest added during year, £23,244; balance of revenue, £66,101; total, £709,440; less cost of further partial renewals of the Java-Australian cables off the Lombok Straits, £18,986, leaving a balance of £690,454. In addition to which £15,401 has been charged against revenue for the cost of completion of the renewals of the Singapore-Saigon cable, and £4,492 for rebuilding staff quarters at Cape St. James. The net result, therefore, of the past year's working is that the reserve fund has been increased by £70,359; the cost of renewals of the Singapore-Saigon and Java-Australian cables, together with the rebuilding of the staff quarters at Cape St. James, amounting altogether to £38,879, have been paid for out of revenue; and 6½ per cent. distributed amongst the shareholders. It will be seen from the printed report that further drawings of the Company's Five per Cent. Debentures have taken place since the close of the half-year, which, when paid off, will reduce the capitals outstanding as follows:—Five per Cent. 1880 issue (the issue having been originally £100,000), £12,500; and of the Australian Government subsidy issue a balance will remain of £417,000, the amount having originally been £640,000. No provision has, however, yet been made for meeting the £320,000 Six per Cent. Debentures falling due in 1891. I hope I shall be able to put before you shortly a scheme for dealing with these debentures. Since the close of the year, the laying of the new cable between Java and Western Australia, to which reference was fully made at the last meeting, has been successfully completed. This extension, which gives the Colonies a third cable to Java, and brings into use the Western Australian land lines as an alternative system to the South Australian overland line, was not needed to meet traffic requirements, the existing cables between Java and Port Darwin having a large margin of carrying capacity, but to strengthen the system and minimise as far as possible the risk of interruptions in the future. The cost of the new cable, about £130,000, will be dealt with in the current year's accounts, and will probably be debited to the reserve fund. As stated in the report, a satisfactory arrangement has been concluded with the Colony of Tasmania for renewing the exclusive privilege of telegraphic communication between Tasmania and Australia, which by effluxion of time would expire next year, and for continuing the subsidy of £4,200 a year for the same period. For some years previously differences of opinion had existed between the Company and the Government as to the interpretation of the contract in regard to the payment of the subsidy after the termination of the twenty years' exclusive concession, the Company contending that by the terms of the contract the subsidy was payable in perpetuity so long as the communication was efficiently maintained, whereas the Government argued that the Colony could not be bound in perpetuity, and that the obligation must cease with the concession. Negotiations were, however, eventually entered into with a view to averting the unpleasantness and uncertainty of legal proceedings, and the following compromise was arrived at, which will secure the Company's position in Tasmania for the next twenty years, namely: The exclusive concession is extended for a further term of twenty years, the subsidy is continued for the same period, a traffic guarantee of £5,600 is given by the Government, and the Company is exempted from all taxation and duties chargeable in the Colony. This arrangement has been ratified by the Tasmanian Legislature and embodied in a formal agreement exchanged with the Government, so that all differences with the Colony are now satisfactorily adjusted. With regard to future operations, I may mention that it is proposed to renew during the current year the shallow water portion of the Saigon-Hong Kong cable, where we have had a great many repairs lately. About 300 nautical miles of cable will be required, costing at least £20,000. The amount expended on renewals and duplications up to date has been £444,239, making, with the £690,454 added to reserve, a total of £1,134,693 taken from revenue since the commencement of the Company's operations. Our repairs, however, are a very serious item, costing annually between £50,000 and £60,000, the cost from the beginning having averaged about £40,000 per annum. Now, gentlemen, I have given you, I think, a very full and accurate statement of our affairs. I have taken you entirely into our confidence, and have shown you what we have done during the last few years. Probably nothing that we have done has given more satisfaction than the prompt way in which we laid the third cable to Australia the other day. When we found that the two cables were interrupted and that the important commercial traffic was consequently severely suffering, we thought that if we were to maintain our position we were bound to give additional security. We therefore did not hesitate to enter into a contract without delay for a third cable, and it is now laid as a reserve. Everything is going on satisfactorily. I might say that we have only one cable interrupted at the present moment, but our duplicate and triplicate cables make the working so safe that that is scarcely worth referring to. As I have said on previous occasions, we know where a break occurs, and it does not alarm us much. The repair, of course, takes time, and there is the cost involved also; but as to being able to effect the repair we have never any doubt. I repeat now, with more confidence than I have said on any previous occasion, that we have now a substantial property to deal with. I may mention—and it is very remarkable, too—that whenever our general meetings come round we have some shareholder who takes a greater interest than others in your Directors' policy. Generally the reference is as to the dividend we ought to pay. A great many suppose that in the midst of our prosperity we ought to go on increasing the dividend every year. The communication we have received this time comes from a lady, who asks why we should not pay 2 per cent. bonus this year instead of 1½ per cent. I think I have shown you in the course of my remarks that we have taken this year out of revenue an amount which far exceeds this ½ per cent. bonus which the lady refers to. We did pay at one time an additional ½ per cent., but in view of these renewals and repairs and the fact that we may next year have to take part in another International Telegraph Conference, when the question of our tariffs may again be discussed, I think you will see the importance of our having a strong reserve fund. We made considerable sacrifices in our rates at the Berlin Conference, and we may find it necessary to reconsider our tariffs at Paris. We have to a great extent recouped the reductions we made at Berlin, and I have no doubt that if we decide to make further concessions at Paris the growth of our business will eventually recoup us for the reduction. I hope, however, that you will give us credit for exercising prudence and protecting your interests. If you do not get the additional bonus in money you get it in the increased price of your shares, and it is difficult for you to have it both ways. I think that a large reserve fund makes us independent, and enables us to meet such an emergency as we had to face the other day, when we laid the Western Australian cable. The more we can strengthen our reserve fund, and make our dividend from quarter to quarter steady, and one that can be depended upon, the more I believe we shall increase the value of your property, and the more we shall be doing justice to the interests of the community we represent. I think I have told you everything that it is necessary for you to know—in fact, everything that we know ourselves—affecting the general interests of the Company; and I say with all confidence that no company can be in a more satisfactory and progressive condition than the Eastern Extension Company at the present moment. I now beg to move:—

"*That the report and accounts of the Directors now submitted be received and adopted, and that a dividend be now declared of 2s. 6d. per share together with a bonus of 3s. per share, both free of income-tax, payable on the 15th inst., making, with the previous distribution, a total payment of 6½ per cent. for the year 1888.*"

The Right Hon. Viscount MONCK seconded the motion.

Mr. JOHN NEWTON congratulated the Directors on the substantial position attained by the Company. So long as their dividend ranged between 6 and 7 per cent. he should be satisfied, and he had no doubt that that feeling would be shared by the majority of the proprietors. With reference to the remark of the Chairman as to submitting a scheme hereafter for dealing with the Six per Cent. Debentures, he hoped that no mortgages would be raised on the property of the Company, and he suggested that there should be a further issue instead of ordinary shares at par to the shareholders, as in every way more advantageous to the Company.

The CHAIRMAN, in reply, observed that he had only, as it were, thrown out a hint in reference to the question of dealing with the debentures, for the reason that 6 per cent. seemed such a large rate of interest for a company in their position to pay. They would do nothing in any scheme that might be proposed that would in any way injure those who had invested money in the Company. The matter was, however, in embryo at present, but perhaps at the next meeting they would have something to lay before the shareholders which would enable Mr. Newton to speak with figures before him.

The resolution was then carried unanimously.

On the motion of the CHAIRMAN, seconded by Lord TWEEDDALE Sir James Anderson was re-elected to his seat at the Board, as was also Mr. F. A. Bevan, on the motion of the CHAIRMAN, seconded by Mr. G. G. NICOL.

The auditors, Mr. Henry Dever and Messrs. Welton, Jones and Co.' were then re-elected.

On the motion of Mr. GIBB, a cordial vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN: There is nothing that gratifies the Directors more than the approval of the shareholders. We are doing our very best to maintain this great system of submarine telegraphy in the position that it ought to occupy—namely, approved by the Imperial and Colonial Governments and by those who use it, and, I may also say, giving fairly satisfactory results to those who have invested in it.

The meeting then separated.

Electrical Power Storage Company (Limited).

The eighth ordinary general meeting of this Company was held on the 10th inst., at Winchester House, Old Broad-street, under the presidency of Sir Daniel Cooper, Bart., G.C.M.G.

The SECRETARY (Mr. Holland Dell) having read the notice convening the meeting,

The CHAIRMAN said: I now propose to offer some remarks and explanations upon the report and the figures in the statement of accounts where they seem to call for observation. During the past year there has been a gratifying increase of business. This increase is mainly made up of a great number of small orders for storage batteries, which are employed for the variety of purposes detailed at length in the Directors' report. By far the larger portion of the gross profit of £13,273. 15s. 3d. has been earned in the manufacturing branch of the business, as the firms and companies on the Continent who have agreed to manufacture E. P. S. batteries under royalty have taken a longer time to complete their arrangements than was anticipated. There is an increase of £165. 5s. 9d. in the item of rates

Digitized by Google

and taxes, owing to the payment of income-tax. We have not done so much advertising lately, so there is a diminution of £293. 6s. 8d. in that account. The shares allotted last year to the Managing Director have been charged against the reserve at par value. The Company has taken out what we believe to be valuable patents in the United Kingdom and in several Continental countries for improvements in details of arrangement in the E. P. S. accumulator, and also for distributing apparatus in connection therewith, and much time and thought has been given by Mr. Frank King, our chief engineer, and our technical staff to perfecting what is commonly known as the E. P. S. system of distribution by storage batteries. On the other hand, law costs and patent fees account is less by £194 2s. 3d., because we have had no professional fees to pay and are for the present free from litigation. The amount allowed for doubtful debts has proved more than ample for the purpose, and there is a balance over which we consider sufficient for this year. There has been, as mentioned in the report, some additional outlay owing to the increase of business on the plant and buildings at Millwall works, and further outlay will have to be made this year. The amount under the heading of sundry creditors is larger, but against this is the increase in sundry debtors account, while the cash balance at the bankers is £3,000 more than it was last year. In the report is given a selection from a long list of new electric light installations in which E. P. S. batteries are used. Reference is also made to various scientific and technical institutions which have adopted accumulators, and I do not think I need here enumerate them. You will have noticed that E P. S. storage batteries are now used for all kinds of purposes—train lighting, ship and yacht lighting, omnibus and carriage lighting, and for power in tramcars, electric launches, and again for surgical purposes. In short, their use is becoming general, as you will have gathered from the paragraphs which have appeared in many newspapers during the past year, and you may take it that, though the name of the E. P. S. Company has not always appeared, yet in 99 cases out of 100 the batteries were the E. P. S. type. Among the latest interesting applications of batteries I would mention the printing at the office of the *East Anglian Times*, at Ipswich, by power supplied by E. P. S. batteries, which are placed at the central lighting station of Messrs. Laurence, Paris and Scott (Limited), in that town, a description of which was sent to the shareholders with the report. I must now dwell for a moment on the subject of central station lighting, the importance of which to this Company cannot be overstated. The Company has applied for Provisional Orders for Paddington, St. Martin's, and the Strand Districts, and an Inquiry is now being carried on under the instructions of the Board of Trade, upon questions which relate to the whole of the applications for Provisional Orders in the metropolis. I shall refrain from making any observations thereon, as the matter is still *sub judice*. I will now pass to the Chelsea Electricity Supply Company, which is supplying light in the Parish of Chelsea. You may not be aware that this is the first company which has supplied electric light in London under the statutory powers of a Provisional Order. It has acquired these powers by Act of Parliament Vic. 50, cap. 18. The E. P. S. Company, in conjunction with the Anglo-American Brush Company and the Callender Bitumen and Telegraph Company, took up the Chelsea Company last July, and contracted to furnish the necessary plant, and they have now carried it through to its present stage; and I feel confident that the combined efforts of the three companies, each in its own special line, will result in a model central station. The system of distribution is that of the E. P. S. Company, by which the current is supplied from the main station to storage batteries placed in convenient sub-stations throughout the district to be supplied. We believe this system to be the best for such populous districts as Chelsea, and that the public will give the preference (when once they become acquainted with its essential features) to the only system in which a reservoir light, in case of accident from any cause whatever, is provided. Our Managing Director, Mr. Courtenay, is a Director of the Chelsea Company, having joined the Board at our request. You will, perhaps, have read the pamphlet issued by the Electrical Accumulator Company of New York. I need only remark that judgment has now been given against the Julien Company for infringing the Faure patent, and therefore that company will be put under injunction. The trial of this suit has taken more than twelve months, and the investigation has been one of a most searching and exhaustive character. The shrewd advisers of the American Company consider, as they state in the document referred to, that they had already got the control of the accumulator business in the States from their other patents, even without the Faure patent, and now that they have this basic patent also declared valid their position should be doubly assured. I beg to move the adoption of the report and accounts, and ask Mr. Sellon to second the resolution.

The VICE-CHAIRMAN (Mr. J. S. Sellon): Gentlemen, in seconding the resolution I have very little to add upon general points to the remarks of the Chairman, or to the matters dealt with in the report. It would, of course, have been gratifying, and doubtless for many reasons acceptable to all of us—and certainly more pleasant to the Directors—if we could have arrived at the conclusion to recommend the division of a dividend. One large shareholder remarked to me after the report had been published that if we had declared a dividend our shares would have immediately doubled in market value. This may be the case, although, in view of what is before us, I see no reason why our shares should not quadruple in value without our troubling ourselves about the dividend at present. In my view, the Directors are bound to consider the exigencies of the business they direct, and are not justified in diverging from what they consider necessary for the protection of the internal interests of the undertaking simply in order to affect the external value of the shares. It has been a labour of years to build up this business, to overcome violent antagonism, and to establish the secondary battery upon a firm basis as an indispensable and reliable factor in electric lighting. This has been at last accomplished, and a first great start given. Would it not be unjustifiable to do anything that might cripple us for a moment in grappling with the great extension of work before us! Instead of diminishing the resources at our command, we could with considerable profit employ further capital; in fact, every £1,000 in a growing business of this kind is of value, and I may say that, realising this, your Directors have not, I think, for at least fully two years taken out any of their well-earned fees. On former occasions I have somewhat exhaustively dealt with most of the technical questions in connection with this undertaking, and I have pointed out the wide and expansive range of work which lies before us. I need not therefore now detain you with any further remarks on such points, but perhaps you would permit me to say a few words on your position as owners of patents. [The Chairman alluded to the recent important decision given in the Courts of the United States in favour of the Faure patent after one of the hardest patent fights on record.] With the exception of one decision—sustaining one of the Thomson-Houston patents for an arc-light regulating device—this is the only electrical apparatus patent pertaining to lighting or motor business the litigation on which in the Courts of the United States has terminated favourably for the patentee. The Faure patent is one of those which, as you know, is held by the Electrical Accumulator Company of America—a powerful corporation formed to work our patent rights in the United States, and in which, I am glad to say, we hold a very considerable interest. The importance of the decision will be obvious to you when I explain that this patent entirely controls the use of active material applied to the plates, and I assure you that no efficient and practical secondary battery can by any known means be made without such application. It is a fundamental and essential point of construction. I ought perhaps to mention at the same time that the Swan patents for the simple perforation of the plates, came before the same Court and was not upheld; but the decision did not arise from any invalidity in the invention itself, but upon a matter of form, proof not having been put forward, probably through an oversight, as to the earlier date of the English patent compared with that taken out in the United States. If considered necessary, this can doubtless be put right, and its priority, which is incontestably capable of proof, can be established. But in any case the matter is of no great importance. Though the patent is an important one in itself, the manufacture of the plates, as carried on by all the infringers, comes within the claims not only of the Faure patent, which is upheld, but of several others in the group of the E. P. S. patents held by the Electrical Accumulator Company. Neither here nor anywhere else where we have patents is this Swan patent affected by any decision of the United States Court. I would take this opportunity of explaining to you that you possess in the E. P. S. group of patents some forty of more or less importance, fully covering each and every point and detail essential to our business; and, so far as is within my knowledge, not one single outside patent exists which would be of use to us in the manufacture, or, as they say in America, would be worth "a red cent" to us. Several of the patents are, as in the case of the Faure, governing or controlling patents in the sense that no economical and efficient secondary battery can be constructed without infringing them. Every perfect plate now made embodies the principle of no less than four of these patents in its manufacture, and in the completed cell others of minor importance as to details come into play. As several of these patents are of recent date compared with our basic patent, you have the great advantage of the prolongation of the term of your practical monopoly of manufacturing storage batteries, because, naturally, the most perfect battery is the one which will always command the market. You will therefore feel justified in considering your position in this important and indispensable branch of the electrical industry to be not only unique but unassailable. I would only further remark that, as time passes and experience is gained, the more absolute is the confirmation of the views put forward by myself and a few others some eight years ago, but doubted and criticised at the time by many electricians, even of eminence, that it is to the employment of the secondary battery that we must look for the attainment of the most reliable, safe, economical, and generally acceptable system of electric lighting; and I confidently anticipate that one of the results of the important investigation now being carried on under Commission of the Board of Trade sitting at Westminster Town Hall—which is literally absorbing the interest of the electrical world of England—will be to enable not only electricians, but the general public, more vividly to realise the solid and permanent advantages of the storage system which this Company advocates and controls. I have the pleasure to second the resolution for the adoption of the report and accounts.

Mr. SCHOMBERG said he had hoped on the receipt of the report to see the prospect of some return for the money he had had in the undertaking now for some years, especially when he saw that the net profit for the year had been £8,372. A dividend of 2½ per cent. on the capital of £150,000 would still have left a balance of £4,622 in the hands of the Directors, which he thought a very large sum to keep in hand to conduct a business like theirs. The Directors stated in the report that it had been a matter for their anxious consideration how to raise additional capital. Instead of the shares being as they were now, 10s., they would have been 15s. had a dividend of 6d. a share been recommended, while they would have been at par had a distribution of 1s. a share been proposed. That would have enabled the Directors to issue the balance of the capital of the Company at par. He congratulated the Directors on their attaining to the position of having no litigation. He would like to know the rate of interest paid on the debentures, and how it was proposed to raise the additional capital.

Mr. J. W. BARCLAY, M.P., said he could not agree with the views expressed by the last speaker. It would be a great misfortune if they were to starve the Company more than it was already. The capital of the Company was still inadequate for the further development of the business that was now opening to the Company, and he thought it would be a great misfortune if the shareholders were further to impoverish the capital by paying a dividend. He believed the course advocated by the Directors, who were large shareholders, was wise and judicious in the ultimate interests o' the Company. His principal object, however, in rising was to congratula the Directors and his brother shareholders on the very greatly mprov.

Digitized by Google

position which the Company had now attained, and he thought that the best thanks of the shareholders were due to the Chairman and Directors for the pluck and energy with which they had striven, and with so much success, to bring the Company from what was well nigh a desperate position into one which gave promise of very satisfactory, he might almost say brilliant, results for the future. He had an idea that the position of the Company was in reality much better than appeared on the face of the accounts. He believed that the inquiry which was going on at Westminster would bring before the public in some intelligible form the merits and demerits of the various systems of electric lighting now in vogue, and he had very great confidence that it would be proved conclusively that the E. P. S. system was not only as economical, if not more economical, than any other, but, in point of fact, the only system which could be relied upon to give satisfaction in electric lighting to the public. If, as he believed, that should be proved, there would be at once an enormous development of the business of the Company, because, if it proved as he had indicated, the whole system of electric lighting, not only in this country, but in Europe, would be dependent upon the supply of the article which their Company manufactured and which it alone possessed. If they turned to the report—and it had been confirmed by the Chairman—they would find that a large portion of the profits had been obtained from the manufacture of the article. and that on a very limited scale ; but he looked to very large profits—perhaps the largest portion of the profits—coming from royalties in other countries, and it was satisfactory to know that arrangements had now been completed in Germany, France, and Austria for the immediate development of the storage battery. That could not fail in the course of the present year, and more so in succeeding years, to bring in a large revenue to the Company. The Chairman had said comparatively little about the American company, in which their Company held such a large interest.

Mr. SCHOMBERG: What is our interest in that company ?

The MANAGING DIRECTOR (Mr. J. I. Courtenay): I will reply to that presently.

Mr. BARCLAY, continuing, said he had reason to know that the American company was in the hands of very able, energetic, and influential men, and he would not be surprised if within the next few years the value of this Company's interest in the American company would be equal to the whole of their capital. If the shareholders would only exercise a little more patience, they would, he had no doubt, reap a brilliant result at no distant period.

A SHAREHOLDER: Did not the first speaker over-state the amount of the profit for last year ?

The MANAGING DIRECTOR: The shareholder is quite right in drawing attention to the fact that the balance at the credit of the profit and loss account is the amount stated of £8,372, but that was not all made in the past year. The debentures bear 7 per cent. interest. With respect to the question of providing further capital, the Directors are not prepared at the moment to lay before you a scheme. I hope in the current year, however, that the Directors will propose a scheme taking into account the debentures that fall due in May next year. It will be necessary in our scheme for obtaining further capital to deal with the debentures, and we also propose to deal with the question of providing further capital.

A SHAREHOLDER: You will not deal with the matter without consulting the shareholders ?

The CHAIRMAN: As to the balance unissued, I dare say, when the shares go to a premium, we may consider the issue of a portion of them. We have to keep shares to the amount of £25,000 in reserve against the debentures. If the shares went to a premium at an early date the position would be very much simplified.

A SHAREHOLDER: The shareholders would have the preference ?

The MANAGING DIRECTOR: My impression is that the shareholders have the preference. The total debentures authorised amount to £25,000, but the Directors themselves have been advancing money to the Company.

The CHAIRMAN: The Directors make themselves personally liable to the bank whenever they want certain money.

The MANAGING DIRECTOR: The debentures are not all issued, but the Directors have advanced money against them, and, as they charge only 1 per cent. above the Bank rate instead of 7 per cent. which the debentures carry, they effect a saving to the Company of between 2 and 3 per cent. In regard to the question of our interest in the American company, I own that we have always been extremely reticent, but the Directors have now desired me to mention it. The total amount of our interest is nominally at par value £120,000, but I urge the shareholders not to form any exaggerated estimates from that statement. I believe that they have control of the business all over America. We are now in the midst of a hot conflict of systems in the metropolis, but I do not believe that the Storage Company will come out the worst.

The CHAIRMAN put the motion, which was unanimously adopted.

The retiring Directors, Sir D. Cooper and Mr. Courtenay, were afterwards re-elected.

The CHAIRMAN returned thanks for his re-election. He assured them that it had been no easy task to manage the Company. He and his colleagues had remained on the Board solely in the interest of the shareholders, and with the determination to do their utmost for them. He would not go into details, but if they had not repeatedly made themselves liable for considerable sums of money the Company would not now have been in existence.

The retiring Auditors (Messrs. Deloitte, Dever and Co.) having been re-elected,

Mr. BARCLAY proposed and Mr. SCHOMBERG seconded a vote of thanks to the Chairman and Directors, and the resolution was carried unanimously.

The CHAIRMAN, in reply, assured the shareholders that the Directors would continue to do all they could to promote the success and welfare of the Company.

Montevidean and Brazilian Telegraph Company (Limited).

The ordinary general meeting of this Company took place on the 9th inst. at the offices, Tokenhouse-buildings, Moorgate-street, under the presidency of Dr. Charles Cameron, M.P.

The SECRETARY (Mr. James Fraser) read the advertisement convening the meeting, and the report of the directors was taken as read. It stated that the percentage of gross revenue receivable from the Western and Brazilian Telegraph Company showed a considerable increase, being £3,604, as compared with £2,508 in 1887, and the directors were glad to note that, so far as could be judged from the published returns of the Western and Brazilian Company, the traffic continued to improve. An amount of £142 was charged against revenue under the heading "New Debentures." This represented the cost of obtaining subscriptions for £8,500 new debentures, bearing interest at the rate of 6½ per cent. per annum, to replace old debentures of that amount which bore interest at 8 per cent. per annum. They recommended the payment of a dividend at the rate of 3s. 6d. per share on the Preference shares (being 1¾ per cent. per annum), which would absorb £1,455, leaving a balance of £54 to be carried forward.

The CHAIRMAN moved the adoption of the report and accounts for the year ended December 31 last. He stated that the present report was more favourable than those which had been submitted on any previous occasion—a fact owing to the improvement in the revenue of the Western and Brazilian Company, on whose earnings their own revenue depended. The auditor's certificate was as follows:—"London, 30th March, 1889. Examined with the books and vouchers of the Company and found to be in accordance therewith. The Western and Brazilian Telegraph Company having objected to an inspection of their books, I have not been able to verify that percentage of earnings payable to the Montevidean Company." This difficulty had arisen under an agreement by which the Platino Company had a right of inspecting the Western Company's books, to which for many years their own auditor had access. After a while, however, the Western Company objected.

A SHAREHOLDER inquired if the point had been legally tried.

The CHAIRMAN replied in the negative, adding that they had not been in a position to spend money on legal proceedings. Continuing, he said he was glad to state that the Western Company had withdrawn their refusal of an inspection of their books, and their accounts had been inspected by the auditor of the Montevidean Company since the issue of the report now under consideration. In future they would meet with no difficulty in that respect. They had been enabled to replace their old debentures, which were issued at a time when the Company was in embarrassed circumstances, and when they were glad to raise money at even 8 per cent ; and they had issued a like amount at 6½ per cent. They had not gained any advantage this year by the alteration, the difference in the old and the new rate of interest having been swallowed up in the commission they had been obliged to pay to the gentleman who had carried out the operation. The old debentures used to be redeemed at the rate of £500 a year, but the Directors considered that that was dangerously slow progress, and the new issue they had arranged, with the shareholders' approval, to pay off at £1,000 per annum.

Lieut.-Colonel G. W. MACAULEY seconded the resolution, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. JOICEY, M.P., the dividend recommended was next agreed to.

Mr. JOICEY then proposed, and Mr. CANTON seconded, the re-election of Lieut.-Colonel Macauley as a director, and the motion was unanimously agreed to.

After the reappointment of the auditor (Mr. W. S. Ogle),

A vote of thanks to the Chairman was passed on the motion of Mr. CANTON, seconded by Mr. PFEIL, and the proceedings then terminated.

The Telephone Company of Ireland.

On Saturday, the 6th inst., the proprietors of this company held their tenth ordinary general meeting at the offices of the Company, Commercial-buildings, Dublin. Alderman Winstanley presided.

Mr. W. F. BOTTOMLEY (Secretary) read the notice convening the meeting.

The report, which appeared in our issue of the 29th March, was taken as read.

The CHAIRMAN, in moving the adoption of the report and statement of accounts, said that a dividend at the rate of 1½ per cent. on the ordinary share capital of the Company for the year ending 31st December last had been declared, and that the *ad interim* paid in August last at the rate of 1 per cent. per annum for the half-year ending the 31st June be confirmed. He said the total number of subscribers, it would be observed, was 970 on the 31st December, 1888. Owing to a change, however, in the mode of keeping the records so as to accord with royalty accounts an exact comparison could not be made, but it might be stated that the increase in the number of the Company's subscribers still continues. The Post Office having opened a telephonic exchange in Cork some years ago, the Directors were for some time unwilling to establish a competing telephone exchange in that city, until it could be seen whether the facilities given by the Post Office fairly met the requirements of the public ; but when, after the Post Office exchange had been opened for more than three years, it was found that the number of subscribers was limited to 30 to a population of about 100,000, whilst the number of exchange subscribers to the Company's telephone exchange in Dublin, with a population of less than 300,000, was upwards of 700, it became obvious that the telephonic wants of the public in Cork were not being duly provided for. The Post Office department and the Directors having obtained permission from the municipality to erect the neces-

Digitized by Google

sary poles in the public thoroughfares, resolved to extend the Company's operations to Cork and the surrounding district. The result had, so far, amply justified the policy of the Board, because on the 1st January, when the Company's exchange was opened, a larger number had already signed contracts with the Company than the Post Office had obtained after three years' work, and the number has already increased to more than 100, which might be considered exceedingly satisfactory for the first three months of the Company's operations there. For the purpose of developing Cork, and opening at Limerick and elsewhere, a call of 2s. 6d. per share was made on the Preference shares. He was distinctly of opinion that the telephone business of the country could be more satisfactorily conducted by private enterprise than under Government control. Personally he was always of that opinion, and he would commend a study of the above figures to those who are always clamouring for Government interference. It is the fashion to commend the administration of the Postal Telegraph Department, but he unhesitatingly asserted that, although the rates charged for telegraph service were very considerably less than in days gone by, still in the days of the old Electric and International Telegraph Company the service between all the more important commercial centres was much more prompt and satisfactory than it is now, and he ventured to say that if the telegraph service in the country were in the hands of private enterprise instead of being under Government control the service would be as cheap and certainly much more satisfactory than it is now. The Company's license from the Postmaster-General was for 31 years from January, 1882, and could not be revoked except by purchase on terms to be settled only by arbitration. He for one trusted, however, that the Postmaster-General would not avail himself of the right which he possessed under the terms of their agreement to purchase out the telephone companies next year, but he did hope that a liberal policy will prevail, and that the companies would be relieved of the heavy royalty of 10 per cent. on their gross revenue which they had at present to pay over to the department, and which was, he considered, an unfair tax upon the most active and progressive section of the commercial community. It was well understood, no doubt, by all the shareholders that the formation of the various subsidiary telephone companies—this amongst the number—effected some years since, was due to the desire of the United Telephone Company to obtain the advantage of the local knowledge and influence of men connected with the various cities and districts in the kingdom to enable the business to be pushed forward rapidly and simultaneously, and but for the obstacles thrown in their way by the dog-in-the-manger policy of the Postal Telegraph Department in the earlier years of the Company's existence much greater progress—satisfactory in one sense as that progress has been—would now be visible. And in this connection he might say that it was greatly due to the exertions of their late lamented Chairman, Mr. E. Dwyer Gray, that the old license from the Post Office was amended in some of its more objectionable features, and a new license granted on somewhat more liberal terms by the late Mr. Fawcett, then Postmaster-General, who grasped the subject in a statesmanlike manner. The business in the various centres having now been firmly established, he thought he ought to tell them that an amalgamation of some, if not all, of the companies, was under consideration, with a view to connecting by trunk wires all the principal centres, thus giving the means of almost instantaneous communication between the more important cities and towns. It might be interesting to some of the shareholders who did not closely follow the development of the telephone to learn that at the present moment there are no less than fourteen wires in constant use for telephonic conversations between Liverpool and Manchester, and the cry was still for more. Only for the misfortune that before this Company was formed the Ulster district had been given over by the United Company to one of the subsidiary companies in England, Belfast would now be connected with Dublin. The Board had actually entered into contracts for the materials of the line in its own district to the County Louth, but the English company preferred rather to develop their large district in England than spend their money here. In the event, however, of the suggested amalgamation of interests taking place, it was possible that the telephone system for all Ireland might be placed under the management here. If that be so, and if the counsel of this Board was followed, the very first step would be to reduce the rates in Belfast to those of Dublin, and to couple up Belfast with Dublin and other towns *en route*. The shareholders will naturally wish to know something about the terms of amalgamation, if such were to come to pass, but all he could say as to that at present was, that the Directors would do their best, consistent with fairness, to obtain such terms as would be satisfactory to the shareholders. He was pleased to say that they were enabled to give the shareholders a small increase in the dividend again upon this occasion. Of course they were aware that the working capital of this Company had been wholly provided by issue of Preference shares, and that each original subscriber to the Preference shares was allotted share for share—one Ordinary share as fully paid up, so as to allow the Preference holders to participate with the United Telephone Company in surplus profits after payment of the dividend upon the Preference shares. Each original subscriber, therefore, who now holds his shares receives £6. 12s. 6d. upon the amount originally subscribed by him, which, under all the circumstances, might be considered, he thought, as satisfactory. It gave him very much pleasure indeed to see amongst them their old friend Mr. Morgan, of London. His presence showed that the working of their Company had given the utmost satisfaction to the parent company.

Mr. ROBERT WORTHINGTON, J.P., seconded the motion, which was adopted.

The CHAIRMAN then moved the re-election of Mr. Arthur Dudgeon and Mr. Robert Worthington, the retiring directors.

Mr. JOSEPH BOND MORGAN, Managing Director of the United Telephone Company, seconded the motion, which was also adopted.

Alderman DILLON moved the re-election of Mr. John M. Kean as auditor, the joint remuneration of the auditor appointed by this Company and the United Telephone Company to be fixed at 50 guineas per annum.

Mr. JAMES EVANS seconded the motion, which was adopted.

Mr. JOSEPH B. MORGAN preposed a vote of thanks to the Chairman, who, he said, had always taken a great deal of interest in the development of telephone enterprise. He (Mr. Morgan) trusted they would always be able to work together in the same harmony and accord. So long as he was connected with the United Telephone Company he would do his utmost to maintain their cordial relations. When the telephone enterprise was just set on foot the Government of the day claimed that it was an infringement on their rights. They had a monopoly of the telegraph system, and the matter went into court, and it was held to be an infringement, but the judge expressed a hope that the Government and the Postmaster-General did not desire to hamper the development of so novel an enterprise. The then Attorney-General, Sir H. James, said the Government had no wish to do that, and that they only desired to have the telephone under their control and to give a license. The license was given after a short time, but as it was only for a limited area, it was found that it hampered the development of the system. Mr. Fawcett, with his broadness of character and pure commercial mind, had the matter brought before him, with the result that they got the license they were now working under. Under the license the system had developed very much, and would have developed more had more facilities been given by the Government with regard to the opening of post offices, &c.

Alderman DILLON seconded the motion, which was adopted.

Alderman WINSTANLEY, in returning thanks, mentioned that last year their gross rentals were £10,193, while this year, taking the first quarter into consideration, they were at the rate of £11,428, showing in the quarter alone an increase of £1,235 over the corresponding period of last year. This was most satisfactory, but of course it included what they had received from the Cork exchange.

The proceedings then terminated.

The Electrical Automatic Delivery Box Company (Limited).

An extraordinary general meeting of this Company was held at Winchester House, 50, Old Broad-street, on Wednesday, April 10, 1889, for the purpose of considering and (if thought fit) passing two resolutions respecting the amalgamation of the Company.

Major R. H. Murdoch presided.

The SECRETARY read the notice calling the meeting.

The CHAIRMAN said that they had been advised that day by their solicitor that it would be best if they dealt only with the resolution relating to amalgamation on this occasion, which he proposed to modify as follows :—

"*Resolved, that it is expedient to effect an amalgamation of this Company with the Automatic Trading Company (Limited), and that with a view thereof the Directors be authorised to take the necessary steps to effect the same.*"

The Directors, he might say, would not have advocated this amalgamation unless they had felt confident that it would be to the benefit of both Companies. The amalgamation ought to lead, he thought, to beneficial results for both sides. He concluded by formally moving the resolution.

Mr. DEAKIN seconded.

Mr. ABRAHAMS (the Solicitor) explained the legal aspect of the case, and stated that both this Company and the Automatic Trading Company would go into liquidation, and that a new company would be formed, and the shareholders of both companies would go into the new company on equal terms.

Mr. PAINTER, a holder of 3,000 shares, was in favour of the proposed amalgamation.

In reply to other remarks upon the subject,

The CHAIRMAN of the Automatic Trading Company stated that the books of that company had been open fully to the inspection of the Board of this Company.

The motion was, after a further discussion, in which the adjournment of the meeting was advocated, put and carried.

The CHAIRMAN then stated that if they failed to carry out the amalgamation the Directors would consider the question of selling the Company if they could get fair and reasonable terms. They had had an offer. He wished at that meeting to tender his thanks to several shareholders who had written to him confidentially making suggestions, for which he was obliged, and which he would utilise. He could assure them that their confidence would not be betrayed.

A vote of thanks to the Chairman for presiding terminated the proceedings.

Reuter's Telegram Company (Limited).

Report to be presented at the twenty-fifth ordinary general meeting of the shareholders, to be held at the Company's offices, 24, Old Jewry, London, on Wednesday, the 17th inst., at noon :—

The Directors report that the net profits for the year ending 31st December last, after payment of current expenses, and deducting rebate on unexpired subscriptions, amount to £1,222. 8s. 6d., including £61. 7s. 11d. brought forward from the last account. In accordance with the Articles of Association the Directors have tranferred £3,448. 15s. 2d. from the reserve fund, of which £538. 4s. 1d. is applied to extinguish bad debts, and the balance of £2,910. 11s. 1d. is carried to profit and loss account. From the amount thereby made available for distribution the Directors declare a dividend of 5 per cent., free of income-tax, for the year 1888. This will absorb £3,686. 18s., and leave a balance of £446. 1s. 7d. to be carried forward.

The Directors have to announce with great regret the retirement of their esteemed colleague Colonel James Holland owing to advanced age. The Hon. Mark F. Napier has been elected to the vacant seat at the Board. In conformity with the Articles of Association, Admiral the Right Hon. Sir John D. Hay, Bart., K.C.B., retires from the direction, but offers himself for re-election. Messrs. Welton, Jones and Co. (late Messrs. Quilter, Welton and Co.) offer themselves for election as auditors.

The dividend warrants are payable on the 27th inst.

NEW COMPANIES REGISTERED.

THE NORTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—Registered by Deacon and Co., 4, St. Mary-axe, E.C., with a capital of £20,000, in shares of £1 each. The object is to carry on a general electric motor and lighting business. Amongst the first subscribers is Mr. R. E. Crompton. The number of directors shall not be less than three nor more than seven. The remuneration of directors shall be determined in general meeting.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 29th, 1889, amounted to £5,351.

EASTERN TELEGRAPH COMPANY.—This company announces the payment by warrant, on May 1st, of interest for the half-year ended 30th April, on their Four per Cent. Mortgage Debenture stock.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—This company notify that the coupon on their Five per Cent. Debentures (1880 issue), due May 1, will be payable on and after that date at the Consolidated Bank, Threadneedle-street, E.C.—The traffic receipts of this company for the month of March were £42,896, as against £39,670 for the same period last year.

INDO-EUROPEAN TELEGRAPH COMPANY.—The board of directors of this company, at their meeting on April 8th, after adding £10,000 to the reserve fund, determined, subject to audit, to recommend the payment of a dividend for the six months ended the 31st December, 1888, of 17s. 6d. per share, making with the interim dividend already paid 6 per cent. for the year, and a bonus of £1 per share, both free of income-tax, making in all 10 per cent. for the year. The dividend and bonus will be payable on and after the 1st May next.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended March 29th, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Company, were £3,993.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The directors of this company recommend that, subject to final audit, a dividend of 12s. per share be declared on account of arrears of dividend on the first preference shares, placing £1,000 to reserve, and carrying forward £1,154.

CHANGE OF ADDRESS.—The offices of Elmore's Patent Copper Depositing Company (Limited), have been removed to 20, Bucklersbury, E.C.

PERSONAL.—The Woodside Electric Company notify that Mr. Rankin Kennedy has ceased to manage their works. The proprietorship, however, remains the same as formerly, and the business will be carried on under the name of the Woodside Electric Company.

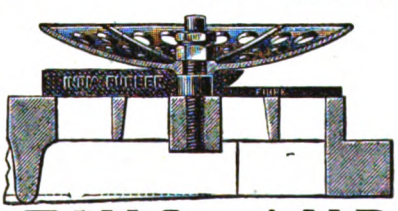
———We are informed that Mr. Neville Moody and Mr. Walter Andreae have established themselves as electrical engineers at 2, Princes-mansions, Victoria-street, under the title of Moody and Andreae. Mr. Moody has been for the last five years with the Anglo-American Brush Electric Light Corporation, and Mr. Andreae was for over two years in the factory of the Anglo-American Brush Corporation, and was subsequently in the employ of Messrs. Schuckert, of Nuremberg. Messrs. Moody and Andreae intend to devote their attention to the supply and erection of plant and apparatus for electric light installations.

———The Acme Electric Works Ferdinand-street, Chalk Farm-road, London, N.W., have been appointed agents for London and a radius of fifty-four miles for the sale of dynamos manufactured by Messrs. F. H. Ryce and Co., of Hulme, Manchester.

———The *Bulletin Financier International* of Rome states that Messrs. Ceresa Formenti and Co., of Lodi, near Milan, have established important works for the manufacture of electric apparatus generally, and in particular for the manufacture of accumulators on a new system invented by Professor Jean Gaudini.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

JABLOCHKOFF'S

DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Johnson & Phillips.
J. G. Statter & Co., Limited.

MANVILLE & MADGEN, *Managing Directors.*

3, PRINCE'S MANSIONS, VICTORIA STREET, WESTMINSTER.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 570.—Vol. XXII. FRIDAY, APRIL 19, 1889. Price Fourpence.

NOTES.

Messrs. Ganz and Co. write to us to the effect that after four years of continuous experiment their electricians, MM. Zipernowski, Déri and Blathy, have succeeded in constructing an alternate current motor, "of absolute practical perfection," which "is in no way inferior to the very best continuous-current motor." Unfortunately the present communication is of a preliminary character, and although it contains an interesting survey of alternate current motors in general, not one word is said about the design or construction of the new motor. Notwithstanding this delinquency we must still attach great importance to any statement put forward in so responsible a quarter and concerning the labours of such accomplished electricians as MM. Zipernowski, Déri and Blathy. We hope shortly to receive full technical details. Meanwhile, the information now to hand amounts to this:—(1) The motor is self-starting, and even the smaller sizes can be placed directly upon a high-tension circuit without danger. Messrs. Ganz point out that in this respect it has a distinct advantage over the continuous-current motor, which at high tension is difficult to handle, and, in fact, cannot be so used below a certain size. (2) Regulation is easily obtained; commercial efficiency over 90 per cent for moderate sizes. (3) The lag introduced is small, so that if the motor is working on a constant potential circuit the maximum value of the current does not become excessive for a given power, as it would if the lag were great. (4) Only one circuit is required. Messrs. Ganz express their conviction that the introduction of this motor completely solves the problem of the distribution of motive power from central stations.

Some weeks ago (*Electrician*, March 1, 1889, p. 474) we stated that a French firm (MM. Worms and Balé) had succeeded after long endeavours in applying electricity to the art of tanning in such away as to immensely accelerate the process. We are now able to give some further information as to the method adopted, and although our knowledge of the art does not enable us to offer any opinion as to the precise value of the invention, yet we are very hopeful that it will ultimately afford an important outlet for electrical apparatus. What is actually done is very simple. The raw hides are placed in large cylinders which revolve upon horizontal axles. Provision is made for passing a current through the drum, the electrolyte being a decoction of tannin. (Further electrical details are at present wanting.) The drum is kept slowly revolving until the process is complete. The time required varies with the nature of the hide. Light calf-skins, sheep and goat-skins, which used to require from four to six months, are said to be completely tanned in 24 hours. Horse and ox-hides require from 72 to 96 hours, whilst by the old-fashioned bark process they would have taken 12 months, or even more. As to the quality of the leather, several French leather merchants have stated that it is above the average in strength, and has all the solidity and suppleness of the best samples. Specimens of harness, &c., made from this leather will be shown at the Paris Exhibition. Furthermore, in addition to the economic value of the immense saving of time, it is stated that the working cost per lb. of dry leather will be only 1¾d. to 2d., as against 3½d. to 4d. per lb., which is the figure now reckoned by the Bermondsey tanners. The number of hands required is said to be only about one-fifth, and the capital expenditure is largely reduced. It is evident that if only half this be true, there is, to say the least, "something in it."

As to the scientific aspect of the question the exact nature of the *rôle* played by the electric current is not at all clear. Prof. S. P. Thompson, who has examined the process, suggests that the effect may be in some way to open the pores of the hides and so permit a more rapid access of the tanning solution, and also that its chemical activity may be increased by the electrolytic action. Mr. A. Zwierzchowski, who is representing MM. Worms and Balé in this country, thinks that the current renders the gelatine more soluble, so that it is able to combine more rapidly with the tannin.

A search in the records of the Patent Office would undoubtedly disclose the fact that this is by no means the first attempt that has been made to tan "by electricity." M. E. Leonardi, in a recent number of the *Revue Internationale de L'Electricité*, mentions several schemes of this nature—all of them failures, the earlier ones necessarily so, from the lack of an economical means of producing current, whilst others suffered equally from a lack of electrical knowledge on the part of the "inventors." It will probably be new to most of our readers to learn that the late unfortunate M. Lucien Gaulard took up this question as long ago as 1877, and after working at it with great industry and determination he obtained results which in 1882 enabled him (according to our informant) to sell the patent rights to an English firm for £1,000, and a royalty on the output. Gaulard's process does not seem to have differed very

Digitized by Google

much from that above described, except that he did not rotate the containing vessel. He also began, for some reason, with a a weak solution of tannin, and gradually increased its strength. The process occupied about 12 days.

We publish this week a Paper by Dr. Doubrava, in which he describes a "method of distribution of continuous electric currents by means of condensers." The Paper possesses some interest for the sake of the theoretical discussion, but at present we gravely doubt its practical value. We ought, perhaps, to suspend our final judgment until Dr. Doubrava is in a position to describe the commutator by which the connections of the condenser are periodically reversed, but we are free to confess that our imagination does not at present extend to the possibility of constructing a practicable automatic device of this class suited for high-tension working.

Speaking of the employment of condensers in the commercial distribution of electricity, we may note that M. Jablochkoff took out a patent for this purpose in France nearly twelve years age; and a very curious patent it is. The inventor proposes to place condensers in parallel across a circuit carrying a high tension alternating current, and to put a Jablochkoff candle in series with each condenser. Now when M. Jablochkoff tried this experiment it seems that he obtained a better result than he had expected, and a result which was also better than that obtained when the candles were in direct circuit with the machine. This led him at the time to suppose that the condenser in some way obtained a supply of energy from the electricity of the atmosphere, and there is a good deal of what M. Jablochkoff now calls "this fantasy" mixed up with the specification. A copy of the specification which we recently received from the inventor has, however, been annotated by him in the light of more recent knowledge, and one of his notes is as follows:—"Pour ma part je l'explique par meilleur rendement des machines à courant alternative dans ce cas que dans le mode d'emploi ordinaire." Mr. Blakesley, who is the recognised authority upon this subject, could probably say whether upon theoretical grounds any such result might be looked for.

The Paper on "Underground Conduits and Electrical Conductors," read by Mr. J. Verity at the last meeting of the Electrical Engineers, afforded a good *résumé* of the present position of this momentous question. We suppose that the scantiness of the audience is partially accounted for by the fact that so many of the members had been dancing attendance all the week at the Westminster Town Hall.

One of the most serious troubles which has arisen in connection with the American conduits, and of which a striking illustration will be found in our American correspondence this week, is due to the leakage of gas and its consequent explosions. In the explosions which occurred last week in New York no personal damage was sustained, although the covers of the conduits which were lifted weighed about 1,600lb. The conduit itself sustained very little damage, and the men working in adjacent manholes were uninjured. All the same, explosions of this kind are decidedly objectionable, and we earnestly hope that the London gas mains are better laid than those in New York. This makes the tenth instance of the kind in New York alone. Even more serious cases have occurred in Chicago, Philadelphia and elsewhere. In one case a steam fire-engine was overturned.

In New York the manholes are brick-lined pits, usually about five feet square and eight feet deep. From manhole to manhole run rows of iron pipes embedded in concrete; the pipes are generally 2½in. or 3in. internal diameter and have screwed joints. The cables, most of which are about 2in. diameter, are passed through the numerous ducts thus provided, leaving a small portion open to the transmission of air or gas. The ducts may safely be assumed to be gas-tight, but the manholes, constructed of masonry, are far from being as impervious as the iron pipes. We also happen to know that in some cases gas-pipes have been allowed to pass through them—a practice which cannot be too strongly condemned. The top of the manhole is tightly closed, the inner lid being forced down by the central screw against a rubber gasket. But the tightness of the cover, which renders the accumulation of gas possible, makes the cause of the explosions a mystery. A mixture of gas and air can only be exploded by actual contact with fire; concussion is without effect; spontaneous combustion is impossible as far as known; external ignition from a cigar or match seems impossible on account of the tightly-fitting lid. The most obvious cause would seem to be an electric static discharge, but it is difficult to imagine how such a discharge could originate. In the present case it is alleged that no current was passing in any of the cables, and in another recent case the conduit contained nothing but telephone cables.

Under these circumstances it is rather startling to learn that in New York, on Tuesday, gangs of labourers, acting by orders of the Mayor, were chopping down the telegraph and electric lighting companies' poles, and removing the overhead wires from Broadway and Sixth-avenue, north of Union-square, and the connecting streets. Madison and Union-squares, with the immediate vicinity, were consequently left in darkness when night came on.

On Thursday and Friday last week Major Marindin conducted an inquiry on behalf of the Board of Trade, at Brighton, into the application for Provisional Orders by the Brighton and Hove Electric Lighting Company, which is opposed by the Brighton Corporation and the Hove Commissioners. The evidence, some of which is of an interesting character, will be found reported at length in this issue.

The appointment of Mr. J. C. Lamb to the position rendered vacant by the death of Mr. Patey as head of the Postal Tele-

Digitized by Google

graphs Department is one that will command general approval in the service, and is especially gratifying to those who know Mr. LAMB personally. No better selection could have been made, seeing that he had acted as Mr. PATEY's colleague uninterruptedly from the date of the transfer of the Telegraphs to the Post Office in 1870. The vacant Third Secretaryship falling to Mr. JOYCE, Mr. LAMB is made an Assistant Secretary; but this is a position Mr. PATEY himself occupied for some time while controlling the Telegraph administration.

AT the Physical Society, on Saturday last, Mr. C. V. BOYS read a Paper on the insulating properties of quartz, which, it appears, are far higher than those of glass, while the former material has the enormous advantage of being practically non-hygroscopic. Since, moreover, the quartz when once it has been melted can be worked very much more easily than glass, this discovery of Mr. BOYS ought to prove of great value in the construction of electrostatic instruments. Every electrician knows the annoyance caused by the necessity of employing sulphuric acid to dry the air surrounding the insulating supports; for, if the acid is forgotten, the gradual accretion of moisture may make it overflow and ruin the instrument. Mr. BOYS stated that even if the quartz was dipped into ammonia, or boiled in a solution of potash, it only required washing with water to completely restore its insulating properties, and when it was raised to a red heat these properties were recovered on cooling. Some quartz, which the author kept for a considerable time in fused potash, did lose its insulating properties to a certain extent, as was to be expected; but even after this treatment the quartz remained a better insulator than glass.

IN connection with the recent very remarkable communication of Prof. OSTWALD in connection with the theory of electrolysis (*The Electrician*, March 1, 1889, p. 493), we would call attention to the views expressed by Mr. J. BROWN and Dr. OLIVER LODGE in the present issue. Prof. OSTWALD's experiment was, in fact, so very remarkable that it is almost a relief to hear that Dr. LODGE has failed to reproduce it.

We do not often sympathise with complaints which seek ventilation in Parliament, but the atmosphere of the Registered Letter Branch of the General Post Office deserves to be considered exceptional, for it cannot get ventilated either with or without Parliamentary aid. The condition of this and other branches of the Post Office when the gas is lighted is said to be almost insufferable. Mr. RAIKES replies that he has recommended the electric light for the whole establishment; but as he goes on to add that he has ordered the introduction of more ventilators, it would seem that he is not quite confident about the coming of the electric light. The delay appears to rest only with the Treasury, and for once in a way we recommend the half stifled employés of the Letter Branches to keep on agitating for the electric light, which they need even more than did those other Branches of the Postal Service who have long enjoyed it.

The Electric Light at Fort Augustus.—The electric light was installed last week in the Benedictial Abbey and School at Fort Augustus, on the Caledonian Canal.

Electricity and Building Operations.—An electric crane is now being used to raise material for some buildings now in course of erection at Brixton. The plant was installed by Mr. L. Fyfe.

Anglo-American Brush Corporation.—The Anglo-American Brush Electric Light Corporation have withdrawn from the Paris Exhibition, owing to their inability to get ready their exhibits in time.

Telegraph Line between Tonkin and China.—An agreement has been concluded between the French and Chinese Governments for the connection of the telegraph system of Tonkin with that of China.

Melbourne Exhibition.—We are glad to learn that Messrs. Felten and Guilleaume, of Mülheim-on-Rhine, have obtained the First-Class Order of Merit with special mention in the Electrical section of the Centennial Exhibition at Melbourne.

Suez Canal and the Electric Light.—The number of ships with the electric light which navigated the Suez Canal by night amounted last year to 1,611, against 395 for the year 1887 This is more than a third of the whole number. The average time taken by the vessels with the electric light to pass the canal is now less than 23 hours.

Northampton.—St. Andrew's Hospital, Northampton, is now lighted throughout by electricity. The plant comprises a 60 horse-power horizontal compound engine by Messrs. Galloway and Sons, two Galloway boilers of 50 and 35 horse-power respectively, and a 600-light Siemens dynamo. The light is much appreciated by the patients and staff.

The Deptford Station.—A 75-ton ingot has just been successfully cast at the Parkhead Forge, Glasgow. It is the first of a set of crank shafts for the London Electric Supply Corporation, and is 20ft. long. The shaft into which it is to be forged is 25ft. long by 36in. diameter. This shaft, with a 12in. diameter hole through centre, will itself weigh 23 tons when completed.

An Electric Tramway between Hemel Hempstead and Boxmoor.—Mr. Sellon, the engineer of the intended Chesham, Boxmoor, and Hemel Hempstead Steam Tramways, stated at a recent meeting of the Hemel Hempstead Highway Board that it was intended to commence the line between Hemel Hempstead and Boxmoor at once, and that a portion of the tramway would be worked by electricity.

A Laboratory for Amateurs.—A correspondent writes us to the effect that he has a small electrical library and laboratory in the north of London, and would be glad to hear of anyone willing to pay a weekly subscription for the use of the same. Should any of our younger readers be in want of some such facilities for experimental work, we shall be happy to place them in communication with our correspondent.

Galatz.—The municipality of Galatz are prepared to receive tenders for the lighting of the town either by gas or electric light. The tenders must be sent in by the 25th of May, O.S. (June 6), and must be accompanied by a deposit of 25,000fr. in cash or Government Securities. Applications in respect of this matter should be made in French or German. Specifications of the requirements of the municipality can be seen at the Municipal Offices at Galatz.

Electrical Coast Communication.—A pamphlet has been published, with the sanction of the Plymouth Chamber of Commerce, advocating the connection of our lifeboat and lighthouse stations along the coast by telephone or telegraph wires. Accompanying it is an admirable map, showing the contrast which the British coast presents compared with that of Denmark in these respects. It is published by R. White Stevens, Parade, Plymouth.

Ship Lighting.—We are glad to hear that Messrs. J. H. Holmes and Co., of Newcastle, have at present orders on their books for the lighting of no less than 16 steamers, in addition to an order which has just been received for a complete installation of the electric light on board a large passenger steamship now building by Messrs. Hawthorn, Leslie and Co. Messrs.

Digitized by Google

Holmes and Co. have also numerous installations on hand in different industrial establishments.

Fulham Vestry.—At a meeting of this Vestry last week, the Law and Parliamentary Committee recommended that the application of the West Middlesex Electric Lighting Company to the Board of Trade for an extension of the time under the Electric Lighting Order Confirmation Act, 1884, be opposed, and that the solicitor to the Vestry be instructed to do so by every means in his power. After considerable discussion the Committee's recommendation was declared carried by a large majority.

Chatham.—A correspondent writes as follows:—"On Thursday last the subscribers to the Chatham Telephone Company were considerably startled by the continual ringing of the bells connected with the telephones. It was found impossible to stop the ringing and other noises which came from the instruments, and on an inquiry being made, it was found that in altering one of the telephone wires it had been placed slightly in contact with the electric light wires, and this caused the unusual disturbances."

Chester.—At the meeting of the Chester Watch Committee last week four applications were received to be allowed to establish stations in the city for supplying the electric light. These applications came from the Chester and District Electric Lighting Company, the Chester and District Electric Supply Company, Mr. H. E. Taylor, C.E., and Mr. R. Potts. A deputation from the first-named company waited on the committee and explained their proposals. The applications were deferred for consideration.

The Elliott Cresson Medal.—The secretary of the Franklin Institute has given notice that the Committee on Science and the Arts has recommended the award of the Elliott Cresson Medal to Edward Alfred Cowper, of London, England, and J. Hart Robertson, of New York, for their invention of a system of fac simile telegraphy, called "the writing telegraph." Any objection to the above recommendation on the score of want of originality in the invention should be communicated within three months to the secretary of the Franklin Institute, Philadelphia.

The Wehr Lightning Guard.—The Wehr lightning guard consists of a bell-shaped piece of zinc, which is in metallic connection with the line, and the upper portion of which has a series of vertical projections on its inner surface. Inside the bell-shaped piece of metal is a brass cylinder insulated by an ebonite disc: its surface is covered with horizontal flutings, and it is connected to earth by a U-shaped prong, which serves at the same time as a support to the whole apparatus. A ring of gutta-percha hermetically seals up the space between the zinc cover and the ebonite disc, thus preventing the introduction of dust and damp.

London County Council and Overhead Wires.—At a recent meeting of the London County Council, it was resolved:—"That as overhead wires, which are daily on the increase in the metropolis, are under no control whatever, the local authorities having no legal power to interfere unless actual obstruction or danger is proved, and as no means exist of identifying or dealing with ownerless wires, it is expedient that all overhead wires should be brought under legislation. That this Council should be constituted the authority for making bye-laws for the registration, regulation, and inspection of all such wires, and that it be accordingly referred to the Highways and Parliamentary Committees to confer and report as to the steps to be taken with this object."

Madrid.—"The failure of the Compañia Española de Electricidad, and the Sociedad Matritense, which was connected with it," writes the Madrid correspondent of *Industries*, "will have the effect of discouraging electrical enterprise in Spain. The industry here suffers partly from a want of technical knowledge, and partly from buyers wishing to buy very cheaply, and, in consequence, getting inferior articles. Very few electrical installations here are capable of doing what was stipulated in the contracts. The time is approaching when the contract should be made for the electric lighting and other electrical requirements of the magnificent building in course of erection for the Banco de España, which is to cost over £600,000.

A Power Station at Rheinfelden.—The three large Swiss firms of Zschokke and Co., Escher, Wyss and Co., and Brown, of Oerlikon, have, says *l'Electricien*, been studying the question of the establishment of a station at Rheinfelden for the distribution of power by electricity. The preliminary surveys have been made, the plans are already drawn up, and a concession from the Government of the Grand Duchy of Baden is now being applied for. The village of Rheinfelden is situated on the Rhine, about 15 kilometres from Basle, and the promoters estimate that about 15,000 horse-power will be available if modern hydraulic plant is installed. It is proposed to erect twenty 750 horse-power vertical turbines, coupled direct to as many 500,000 watt dynamos, giving 2,000 volts and 250 amperes. Several dynamos will be connected in series, and a series system of distribution will be employed.

West African Cables.—The cables for the West African and the Eastern and South African Telegraph Companies are now in process of being laid. Up to present date, the "Silvertown," belonging to the India Rubber, Gutta Percha and Telegraph Works Company, has completed the section between Bonny and Principe, distance about 202 cable miles. The "Scotia," belonging to the Telegraph Construction and Maintenance Company, has completed the cable between Cape Town and Port Nolloth, cable distance about 350 miles. The next section to be laid by the "Scotia" is between Port Nolloth and Mossamedes (distance about 1,172 cable miles), where it is expected she will meet the "Silvertown," when the latter ship has laid the Loando-Benguela (280 miles) and the Benguela-Mossamedes (250 miles) sections, thus completing an alternate telegraphic communication between Europe and the Cape of Good Hope *viâ* West Coast of Africa. This work will establish a complete line of telegraphic communication round the Continent of Africa, the first continent thus electrically embraced.

Electric Traction in Liverpool.—We understand that the directors of the Liverpool Tramways Company having carefully considered almost every available system of mechanical traction have decided to give a fair trial to the accumulator cars of the Electric Traction Company. Sir David Radcliffe, the chairman, and Mr. O'Neill, the manager, recently paid a visit to the Electric Traction Company's installation on the Barking-road section of the North Metropolitan Tramways Company, and after seeing the cars at work and inspecting the charging station, these gentlemen reported to their Board that this system was the best adapted for use on tramways, especially in the crowded streets of large towns, and arrangements have now been entered into between the Liverpool Company and the Electric Traction Company and North Metropolitan Tramways Company to supply a car for experimental purposes, together with the necessary electrical equipment, similar to those which are now running on the North Metropolitan section between Canning Town and Green Gate, Barking-road.

Electric Transfer Table at Altoona, Pa.—The Pennsylvania Railroad Company are using a Sprague motor equipment for the purpose of operating a large transfer table recently put up at their Altoona workshops. The armature shaft actuates the main driving shaft of the table mechanism through spur gearing. The motor is a 10 horse-power machine, and the current is supplied from a dynamo 600ft. distant. The weight of the motor is about 900lb. The speed of the table can be regulated from 100 to 300ft. per minute, according to the loading. The motor is suspended by springs on the end distant from the driving shaft of the table, so that the armature can rotate slightly, probably about one-tenth of a revolution, before the table starts. The table at Altoona is 60ft. long and 17ft. wide, traversing a distance of 295ft. The potential of the current used is 125 volts at the dynamo, which is decreased to about 110 volts at the motor. A table of this type is now being built by the Sprague Electric Railway and Motor Company for the Philadelphia and Reading Railroad.

The Proposed Telephone Convention.—A meeting of the committee formed to promote the holding of a Telephone Convention during the present year was held on Wednesday, 3rd April, at the Institution of Electrical Engineers, Colonel Jackson in the chair. It was resolved:—That it is advisable to hold a Telephone Convention at some time this year to be decided hereafter. That the Convention shall be formed of

Digitized by Google

the managers and staff of the United and subsidiary companies, managers and staff of Post Office exchanges, foreign companies having offices in London, and such gentlemen as the committee may decide. That foreign telephone administrations and companies be invited to send delegates to the Convention. That manufacturers of telephonic appliances be invited to attend the Convention. That a sub-committee be formed, consisting of Messrs. Fletcher, Kingsbury, and Maier, to draw up the necessary circulars, and to attend to other business to be submitted to the general committee. It has been suggested to hold the Convention during the stay in London of the American electricians on their way to the Paris Exhibition. This will probably be early in August.

The Proposed Bermuda-Halifax Cable—Its Usefulness for Weather Predictions.—The announcement made by the British Postmaster-General, says the *New York Herald*, that the Government intended to lay a submarine cable between Bermuda and Halifax, will be good news to all Atlantic seamen and all American and European meteorologists. Bermuda is a natural observatory for watching hurricanes emerging from the tropical ocean and threatening to assail the United States or to advance north-eastwardly from the Gulf Stream into the transatlantic steamer tracks, and subsequently to burst upon the shores of Europe. Of course an observer at Bermuda cannot see with the naked eye what a Gulf Stream storm is doing, or determine by ocular demonstration what its course will be. But by watching the fluctuations of the barometer at this mid-Atlantic station, and by reporting them by cable to America and Europe, meteorologists on either continent will be enabled to feel the pulse of the storm and to determine more accurately its intensity and its future movements. For purposes of weather and storm forecasting in our Atlantic States, therefore, weather cablegrams from Bermuda will be invaluable.

Lighthouse Illuminants.—We (*Journal of Gas Lighting*) learn that there is a prospect of the inquiry in reference to lighthouse illuminants being reopened, with a view to a final settlement of the question at issue. The report on the South Foreland experiments of 1885, it may be remembered, failed to achieve that result. The most recently issued parliamentary papers on the subject include memorials to the Prime Minister from the leading shipowners at the various ports on the Clyde, the Tyne, and the Mersey, as well as at Dublin and Belfast, all expressing dissatisfaction with the South Foreland report. They propose that one of two courses should be adopted —either that a Royal Commission should be appointed to carry out further experiments in lighthouse illuminants, or that the criticisms of the recent report should be submitted to the judgment of independent scientific experts. As the result of an interview which Sir Michael Hicks-Beach lately granted to Mr. J. R. Wigham, whose system of gas illumination, it will be remembered, figured conspicuously in the South Foreland experiments, arrangements have, we believe, been made for the appointment of a committee, consisting of the President (Professor Stokes) and two Fellows of the Royal Society, to deal with the whole matter.

Conduit Explosions in New York.—The following paragraph was omitted from our New York letter of last week:—Quite a sensation was caused in this city on Monday last by a series of explosions in the subways in front of the Fifth Avenue Hotel at the corner of Broadway and Twenty-third Street. These explosions occurred just about midday, and the possibility of serious results will be understood when I state for the benefit of your readers who have never visited our city that the corner is just as busy and bustling a one as that at Oxford-circus. There were three or four explosions all within a few seconds of each other. The manhole covering and the heavy Belgium pavement, earth, &c., were scattered in all directions. A few hours later the place would have been thronged with ladies out shopping. As it was, there were plenty of them about, and one was thrown to the ground. A cab in front of the Hotel was overturned, and with it the cabman, and a messenger boy was blown up six feet in the air, attaining a greater rate of speed than he had ever reached before. The Subway Board took immediate action, notifying each of the five gas companies operating mains in the vicinity of the explosion that the accident had occurred, and asking them to take steps to prevent further leakage of gas into the subways. The general uneasiness of the public mind on this subject has not been lessened by another explosion down town in Liberty-street, where a huge escape of steam from the steam heating-pipes occurred, startling passers-by, and leading for a time to an interruption of traffic.

Electric Lighting Scheme for Weybridge.—Last Friday week a public meeting was held at Weybridge to consider the subject of the public lighting of the town. At a previous meeting a committee had been appointed to consider the matter, and Dr. Sealy now read their report. They had had before them three systems of public lighting—gas, oil, and the electric light. The Walton Gas Company offered to erect from 50 to 100 lamps for £2 per lamp complete, and to supply them with gas from October 1 to March 31, from sunset to midnight, at £1. 19s. 10d. per lamp. About 85 oil lamps of 35 candle-power, with posts, &c., complete, could be erected, lighted, and extinguished for 26 weeks, from dusk to midnight, all responsibility of breakage, &c., being borne by the contractor, for £295. A considerable desire existed in the neighbourhood for electric lighting. An offer had been received to erect the necessary plant and supply the lamps on the incandescent system at 45s. per lamp, the light thus supplied to be available during the summer as well as the winter months, from dusk to, say, 1:30 a.m. The Committee unanimously recommended this method, "being most in accord with the age in which they lived, as well as from every point of view most economical and desirable." After discussion, lighting inspectors were appointed, with power to make further inquiries, the sum to be expended by them to be limited to £230. We trust that the inhabitants of Weybridge quite understand what they have to expect from incandescent lamps employed for out-door illumination. We fear that to many of them an "electric light" is an arc light and nothing else.

Search Lights and Torpedo Boats.—The utility or otherwise of the electric search light for torpedo boat work was tested in a very practical manner in the recent night manœuvres of the Spanish torpedo boat flotilla, the result of which proved not only its utter inutility for search purposes, but that its employment became a source of danger to the boat using the light by reason of its showing her position to the enemy rather than *vice versâ*; and the result of a conference of the commanders of the various boats engaged in these night exercises was that the electric search light was entirely done away with on board these ships. The writer of the report states his preference for blue lights, Drummond rockets, &c. The experience gained with the electric search light when used from torpedo boats, therefore necessarily not placed high enough above the water, as set forth in the report, demonstrates the immense difference between its use in harbour and at sea. It was found that in harbour, when the beam of light was thrown on the fortifications, breakwater, and other objects at distances from 984 yards to 2,780 yards, they were clearly seen, even from the torpedo boats adjoining the one which was experimenting with the light, while at sea, and at the same distances, the land showed quite confused, nor was it possible to distinguish details. Throwing the beam of light out towards the sea for the purpose of discovering ships, the sea had the appearance of a brilliant fog; the low position of the light makes the beam extend over the water a long way, lighting up the water in which the boat is travelling and even the broken water made at the bows and passing the sides of the boat; further, the light is reflected from the deck, which is lighted by a luminous atmosphere which prevents anything being seen in the sector explored by the light, and still more so over the rest of the horizon, which is plunged in such obscurity that nothing can be seen. The electric light failed to discover a torpedo, landwards or seawards, though the position was approximately known. The electric light fixed the position of the boat using it. The fitting of the electric search lights prevented an object being rapidly focussed and its movements being followed if the object moved rapidly. The writer of the report attributes the difference of power in seeing objects illuminated by the electric search light in harbour and at sea as due to the influence exercised by familiarity with the region examined, and our experience agrees entirely with this view.—*Engineering.*

ON OSTWALD'S EXPERIMENTS ON ELECTROLYTIC DISSOCIATION.*

BY J. BROWN, BELFAST.

An expression of opinion is asked concerning the experiments and theory of Prof. Ostwald as published in *The Electrician* for March 1st.

On p, 3 of the reprint, Prof. Ostwald "assumes that a solution of potassium chloride contains many free ions of $\overset{+}{K}$ and $\overset{-}{Cl}$."

To talk of "free" ions seems to me a contradiction in terms which would have met with the strongest disapproval of the originator of the word "ion."

In the very paragraph in which Faraday defines "ion" (*Exp. Res.* I., p. 197), he expressly repudiates, as implying too much, the names electro-positive or electro-negative as applied to substances "according as they go under the supposed influence of a direct attraction to the positive or negative pole," and his whole theory of electro-chemical decomposition implies that "the free substance cannot travel, the combined one can" (*ibid*, p. 157).

I submit that Faraday's definition should stand till we have clear experimental evidence to prove its inaccuracy, and I would respectfully suggest that if anyone wants to describe a "free molecule or atom, with a hypothetical electric charge, wandering about in a solution," he should invent a new name for it.

I do not write this from any pedantic regard for words, definitions, or authorities, but from a feeling that it is just possible there might be, in the polar or two-ended nature of the molecules of an electrolyte, some relation, deeper than has yet been discerned, with the polar or two-sided nature of the electric current accompanying their decomposition — "dissociation theories" notwithstanding; and it seems inadvisable to put this out of sight by altering the original meaning of the word "ion." Although Prof. Ostwald at first assumes the existence of "free ions," he concludes the description of his experiments on p. 494 with the remark, "This shows that the slightest motion of electricity in the electrolyte . . . cannot take place without a corresponding motion of the ions; it follows as a necessary consequence that the ions are free."

It is almost needless to point out that there are other ways of explaining the transference of substances in an electrolyte accompanying the movement of electricity (current) in it which do not imply "free ions," and are equally applicable to the experiment in question.

The explanation of Prof. Ostwald's arrangement seems simply this: The positive pole of the electric generator is connected to the tinfoil on A, and the negative through the earth to the mercury in C. A current passes till certain charges have accumulated on opposite sides of the glass walls of A, and is accompanied by the usual electrolytic phenomena, on which the experiment, so far as described, does not appear to throw any new light. It is, in fact, somewhat like a Lippmann electrometer, with a Leyden jar to be charged instead of a large surface of mercury to be polarised.

Prof. Ostwald attributes the observed effect to the influence of a "statical charge," but in both modifications of the experiment electricity in motion (current) is expressly mentioned as accompanying the phenomena.

It is difficult to see how the experiments are supposed to prove the particular hypothesis mentioned in the first part of the Paper, or why that hypothesis specially "explains" those experiments.

* A communication to the Electrolysis Committee of the British Association.

The Brazilian Submarine Telegraph Company.—The numbers of the Five per Cent. Debentures of this Company which are to be paid off on the 31st July next will be found in our advertisement columns.

ON THE DISTRIBUTION OF CONTINUOUS ELECTRIC CURRENTS BY MEANS OF CONDENSERS.

BY DR. STEPHEN DOUBRAVA.

The application of condensers in connection with electric lighting was first tried, for aught I know, by Jablochkoff. Afterwards the same idea was taken up by Gravier, who especially intended to use condensers for the distribution of continuous currents.

Without discussing the many objections raised against that principle of distribution, I intend to show in that which follows that condensers may prove useful for feeding incandescent lamps (of E.M.F.) in multiple arc, if continuous currents of a somewhat higher tension (200, 300, 400, 500 or more volts) are used.

The current obtained by charging and discharging a condenser is dependent upon its capacity, and upon the number of discharges per second. It does not matter what the resistance of the circuits (both of charging and of discharging) may be, provided they are not too great to prevent the condenser from being completely charged or discharged.

Let G (Fig. 1) represent the generator, the E.M.F. of which we may denote by E, supposing it to be constant. Now imagine the condenser being charged along the circuit $a\,b\,c\,d$, and afterwards discharged along another circuit $e\,f$ by means of any suitable contrivance.

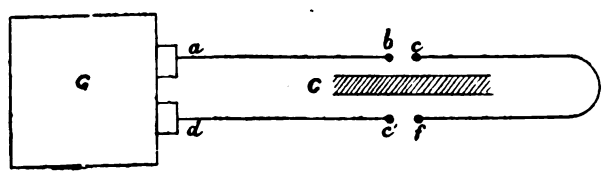

Fig. 1.

Let us consider first what happens during charging the condenser.

Be R the total resistance of the circuit $a\,b\,c\,d$,
L its coefficient of self-induction,
F the capacity of the condenser, and
P its potential at a certain time, t,
C the current at that time.

Then
$$R\,C = E - P - L\frac{d\,C}{d\,t} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Further
$$C = F\frac{d\,P}{d\,t} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

From (1) we obtain
$$R\frac{d\,C}{d\,t} + \frac{d\,P}{d\,t} + L\frac{d^2\,C}{d\,t^2} = \delta \quad . \quad . \quad . \quad . \quad (3)$$

and by substituting for $\frac{d\,P}{d\,t}$ the value from (2) we have
$$\frac{C}{F} + R\frac{d\,C}{d\,t} + L\frac{d^2\,C}{d\,t^2} = 0 \quad . \quad . \quad . \quad . \quad (4)$$

This equation will represent the course of charging. A particular integral of it is—
$$C = A\,e^{\alpha\,t} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

and this, with (4), gives
$$L\,\alpha^2 + R\,\alpha + \frac{1}{F} = 0,$$

whence
$$\alpha = -\frac{R}{2L} \pm \sqrt{\frac{R^2}{4\,L^2} - \frac{1}{F\,L}} \quad . \quad . \quad . \quad . \quad (6)$$

The total integral of equation (4) will be therefore
$$C = A_1\,e^{\left(-\frac{R}{2L} + \sqrt{\frac{R^2}{4\,L^2} - \frac{1}{F\,L}}\right)t} + A_2\,e^{\left(-\frac{R}{2L} - \sqrt{\frac{R^2}{4\,L^2} - \frac{1}{F\,L}}\right)t} \quad . \quad (7)$$

The two coefficients A_1 and A_2 of integration may be easily found by resorting to the limits of the values of C and t.

Digitized by Google

We shall now inquire about the amount of energy spent by the generator in charging once the condenser, and the relation of the energies in the charging and discharging circuits.

The energy given by the generator during the interval dt is $E\,C\,dt$, the energy spent in the charging circuit will be $\left(R\,C^2 + LC\frac{dC}{dt}\right)dt$, and the energy used in charging the condenser $C\,P\,dt$.

The complete charging will require a certain time τ, therefore

$$E\int_0^\tau C\,dt = \int_0^\tau P\,C\,dt + R\int_0^\tau C^2\,dt + L\int_0^\tau C\frac{dC}{dt}dt \quad . \quad (8)$$

The integral $\int_0^\tau C\frac{dC}{dt}dt = \frac{C^2}{2}\Big\}_0^\tau = \theta$, for the current is zero at both the times θ and τ.

$$\int_0^\tau P\,C\,dt = F\int_0^\tau P\frac{dP}{dt}dt = F\frac{P^2}{2}\Big\}_0^\tau = \frac{F\,E^2}{2},$$

P being θ and E respectively at the times $t = \theta$ and $t = \tau$.

In similar manner we get

$$E\int_0^\tau C\,dt = E^2\,F.$$

Therefore (8) will become

$$E^2\,F = R\int_0^\tau C^2\,dt + \frac{E^2\,F}{2} \quad . \quad . \quad . \quad . \quad . \quad (9)$$

or

$$R\int_0^\tau C^2\,dt = \frac{E^2\,F}{2} \quad . \quad . \quad . \quad . \quad . \quad (10)$$

From this we see that the heat generated in the charging circuit equals the energy stored up in the condenser, and from the fact that the latter in discharging the condenser appears as heat in the discharge circuit, it follows that *the former quantity of heat must be equal to the latter.*

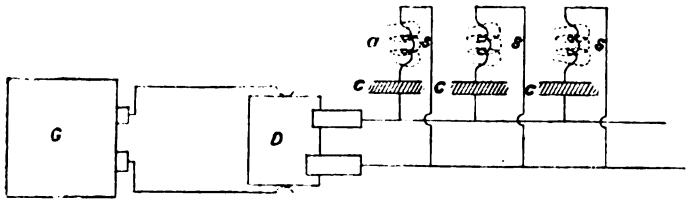

FIG. 2.

Therefore, considering the energy in the discharge circuit as useful work, there would be a loss of 50 per cent. of the whole energy absorbed in the charge circuit. But letting the two circuits coincide, it is seen at once that the whole energy may be rendered useful.

I will now proceed to show how such a system may be applied to the distribution of continuous currents.

The continuous current is conducted to certain points of distribution, where, by means of a peculiar disjunctor (the construction of which I cannot publish at present), it is reversed periodically. These reversals are used to charge condensers, in the circuit of which are placed induction coils; the secondary windings of the latter feed incandescent lamps. Fig. 2 represents the whole arrangements where G is the generator, D the disjunctor, C the condensers, S the inductors, and Q the lamps.

The area of a condenser necessary to feed a 16-candle lamp does not exceed one square metre supposing the E.M.F. of the generator to be 100 volts, and it can therefore be easily put in a small box. The inductor, too, is a very small one (some centimetres length), and may be applied directly to the lamp fittings. The cost of such a condenser and inductor (per 16-candle lamp) will be about eight shillings. By the arrangement described above I have already obtained an output of 97 per cent.

THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 13th inst., Mr. SHELFORD BIDWELL, F.R.S., exhibited

"A Lecture Experiment Illustrating the Effect of Heat on the Magnetic Susceptibility of Nickel."

It is well known that nickel loses its magnetic susceptibility when heated, and that this loss occurs at a very much lower temperature than in the case of iron. This property is shown very neatly by a simple piece of apparatus designed by Mr. Bidwell. A small copper disc is suspended by means of two hooks and a pair of threads from a support, so that it can swing in its own plane, forming, in fact, the bob of a pendulum. A small bar of nickel projects on one side from the edge of the disc, and opposite to this nickel bar is a steel bar-magnet fixed in a horizontal position in such a way that when the nickel is in contact with the magnet the pendulum deviates slightly from the vertical. The copper disc is blackened in order that when heated it may cool again as rapidly as possible. When the apparatus is left to itself the nickel is attracted by the magnet and remains in contact with it. When the nickel bar is heated by means of gas flame, it almost immediately loses its magnetic susceptibility and ceases to be attracted; it therefore swings away from the magnet in obedience to gravity. By the time that it is swinging back towards the magnet it has become cool enough to have regained its magnetic susceptibility, and is therefore again attracted by the magnet, but it falls away again almost immediately owing to its being brought into the flame. Mr. Bidwell states that if the flame is kept steady the oscillation can be kept up for some ten minutes. It forms an exceedingly pretty experiment for lecture purposes. Mr. Bidwell then exhibited an experiment illustrating his recent discovery of an effect of light upon magnetism, which was shown before the Royal Society on March 21st, and described in *The Electrician* of March 22nd.

In the discussion which followed—

Prof. S. P. THOMPSON inquired whether Mr. Bidwell had obtained any data which would enable him to compare the action of light upon the magnetised bar with its effect upon selenium.

Mr. WHIPPLE stated that the late Mr. J. A. Broun had noticed a similar unstable state with regard to magnetisation in the case of a bar which had been demagnetised by placing it in hot water.

In reply to Prof. THOMPSON, the author observed that it was not generally admitted that the resistance of selenium was always increased by the action of heat, for, although this certainly occurred with some specimens, there was strong evidence that in other cases the opposite effect was obtained. It could not therefore be taken as a proved fact that the effects of light and heat on selenium were invariably of an opposite character. He had not obtained any data which would afford a basis for a numerical comparison between the action of light on the prepared bar and on selenium, but the suddenness of the primary effect, followed by its gradual increase, was exactly similar to what occurred in the case of selenium. In reply to another question, the author stated that he had endeavoured, by using a prism, to observe the action upon the bar, of light from different portions of the spectrum, but he had been unsuccessful hitherto, as the intensity of the light was insufficient to produce a sensible effect. He had, however, tried the effect of placing strips of glass of various colours in the path of the beam of light, and he found that the light from the red end of the spectrum produced more effect than that of the violet end, but this was only what was to be expected on account of the greater energy possessed by the rays from the former portion of the spectrum.

Mr. G. M. WHIPPLE then made a communication to the Society—

"On the Dark Flash seen in some Lightning Photographs."

The author referred to the fact that some two years ago the Meteorological Society had issued a circular asking for photographs of lightning flashes, and in reply to this circular a large number were received from different parts of the world, but chiefly from France and Belgium. Prints from these photographs have been pretty widely distributed, and have attracted considerable attention. It will be remembered that a great deal of interest was excited by the ribbon-like character of the markings observed in the photographs of some of the flashes, and still more by the so-called *dark flash*, namely, a dark mark on the surface of the photograph having all the characteristics of a lightning flash except in its being dark instead of light. Prof. Stokes had suggested that the dark flash might be caused by one flash following exactly the same path as another immediately preceding it, and having some of its light cut off, more especially the highly refrangible rays which would mainly affect the photographic plate, by having to traverse the nitrous oxide gas formed by the decomposition of ammonia during the passage of the first flash. With respect to the ribbon markings, it occurred to the author that they might be due to the photographs having been taken through the glass of a window. He had not yet had the opportunity of testing this by actually taking photographs of lightning flashes through interposed

Digitized by Google

sheets of glass, but he had endeavoured to get an effect somewhat similar to that of a flash by drawing a wavy chalk line on a black board and photographing it after having previously interposed a sheet of plate or window glass slightly deviating from the plane perpendicular to the axis of the lens. These photographs, which were exhibited to the Society, showed a remarkable likeness to the ribbon markings observed in the photographs of the lightning flashes, and it seems probable that this may be the true explanation of them. It occurred to the author that the dark flash observed on some of the prints might have been due to a somewhat similar cause, namely, to internal reflection within the glass of the negative plate, and he pointed out how such an effect might be produced if the printing was effected by means of sunlight falling somewhat obliquely upon the negative. He had tried to test this by means of photographs of the chalk lines drawn upon the black board, but he had been unable to make many experiments owing to the recent weather having been unsuitable for printing. He showed, however, a photograph which exhibited, though not very perfectly, an effect of the kind.

In the course of the discussion which followed—

Dr. GLADSTONE said that though he naturally hesitated to criticise anything that Prof. Stokes had suggested as an explanation of an optical phenomenon, yet he found it very difficult to imagine that one flash should follow so exactly the same path as one which had just preceded it, and it also appeared difficult to believe that a sufficient quantity of nitrous oxide could be produced to show the observed effect. He stated that some of the photographs which showed the dark flash very clearly had been taken by a Mr. Shepherd at Westbourne-grove, so that the negatives would probably be available, and an examination of them would decide between the two explanations; for if Mr. Whipple's explanation was the true one, the dark flash would not be shown upon the negative.

Mr. BOYS stated that he always made a point of observing a lightning flash whenever possible, and that he had often observed a series of flashes following immediately one after the other in exactly the same path, every turn and twist in one flash being observed in those which followed it, and the whole series occurring in a fraction of a second.

Mr. C. V. Boys then read a note

"On Quartz as an Insulator."

He stated that when making quartz fibres by the process described by him some time ago of shooting an arrow carrying with it a kind of tail of softened quartz, he had observed that, when the fibres were very fine, if they broke off between the bow and the target the extremities assumed the form of a screw about half an inch in diameter and some eight or ten inches long. If any body were brought near this screw, the end of it would shoot out towards the surface of the body, retracting again when the body was removed. It hardly appeared possible that this could be due to any other cause than to the fibre becoming in some manner electrified during its formation. It, however, this were the case, it would show that quartz must be an exceptionally good insulator under ordinary atmospheric conditions, for otherwise the extremely minute charge which could be carried on so fine a fibre would be dissipated almost as soon as it was generated. It was, of course, quite impossible to obtain any direct proof of the existence of so small a charge beyond that given by the behaviour of the screw when any substance was brought near to it. He therefore determined to test the insulating power of quartz under ordinary atmospheric conditions, and he found that quartz is under any circumstances a better insulator than glass, and that under the ordinary atmospheric conditions there was no comparison between them. This was very well shown in an experiment which Mr. Boys exhibited to the Society. A pair of gold leaves had been suspended by means of a hook formed out of a thick quartz fibre, inside a case with glass ends, and had been electrified about five hours before the time of meeting. In order to make the conditions as unfavourable as possible, the air within the case was kept moist by placing a glass dish full of water inside it and the quartz hook was made very short. When the experiment was exhibited the deflection of the gold leaves had only diminished by about one-fourth of its original amount. If glass had been used as a support for the leaves the electrification would have been entirely dissipated in considerably less than a minute.

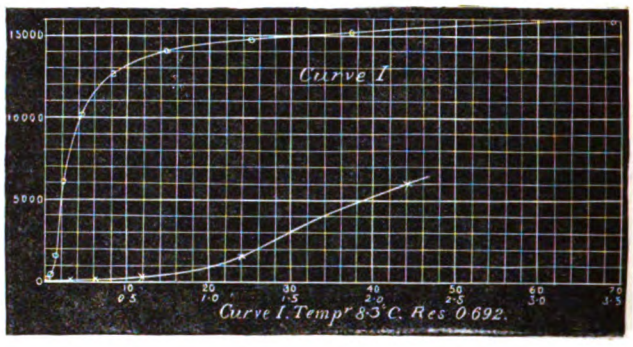
MAGNETISATION OF IRON AT HIGH TEMPERATURES.*

BY DR. J. HOPKINSON, F.R.S.

I have recently been making some determinations of the curves of magnetisation of iron at varying temperatures up to that at which the iron ceases to be magnetic. Although the experiments are still progressing, some of the results are of sufficient interest to be worth publishing briefly at once.

The method of experiment was identical with that which I used for a sample of nickel about a year ago. The temperatures are estimated by the resistance of a copper secondary coil, and, as there may be some uncertainty as to what temperatures the several resistances correspond with, I give in the curves which follow the resistance observed as well as the temperature estimated.

Curve I. shows the relation of induction to magnetising force ta the ordinary temperature, the resistance of the secondary coil

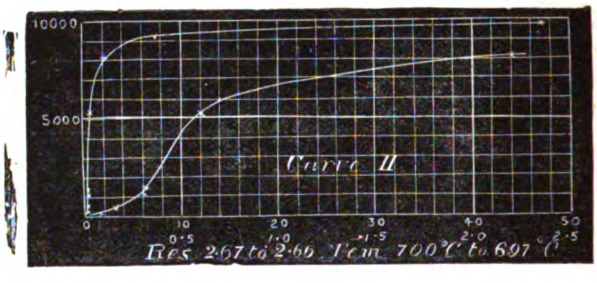


being 0·692 ohm. The curve is given to two scales, the scale of induction being the same in each, whilst the scale of magnetising force is magnified twenty-fold in the one as compared with the other.

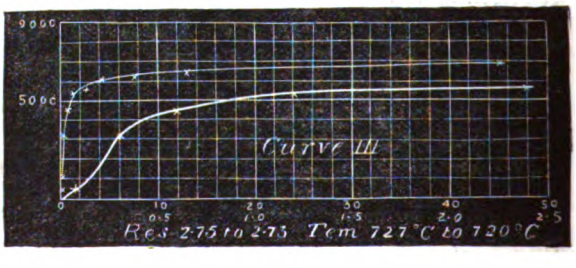
Curve II. shows the same relation for a temperature of 697° C. to 700° C.

Curve III. shows the same thing for a temperature between 727° C. and 720° C.

These curves illustrate what has been long known, that rise of temperature causes increase of induction if the magnetising force is small, but diminution of induction if the force is great.



In Curve IV. the abscissæ are temperatures, the ordinates are the ratios of induction to magnetising force or permeabilities for a force of 4·0 and of 0·3 C.-G.-S. units, the data being supplied from the preceding and other curves. The latter curve brings out a most remarkable feature. For this force the permeability increases somewhat steadily to a temperature of about 640° C.; its rate of increase then rapidly accelerates till it attains a maximum of 11,000 at a temperature of 827° C.; at 737° C. the permeability is practically unity or the magnetisability of the material has entirely disappeared.



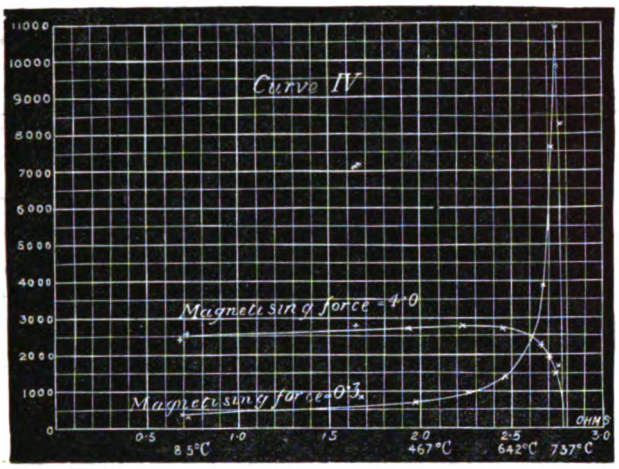
Regarding the iron as made up of magnetic molecules, the axes of which are directed to parallelism by magnetic forces, the results are expressed by saying that the magnetic moment of the molecule diminishes with rise of temperature, at first slowly, but very rapidly as the point is approached at which magnetism disappears; on the other hand, the facility with which the particles are directed continually increases, at first slowly, but at high temperatures very rapidly. The effect is that at a temperature of 720° C. an exceedingly small force is competent to turn the axes of nearly all the molecules in a direction parallel to the magnetising force.

* Paper read before the Royal Society, March 14, 1889. Preliminary Notice.

Digitized by Google

The estimates of temperature given herein must be accepted as provisional, and subject to revision. The actual temperatures are undoubtedly materially higher, as I have not yet taken into account the part of the secondary wire outside the furnace.

[If an iron ring which has never been magnetised has its curve of magnetisation determined for an ascending series of forces, if it be then thoroughly demagnetised by a succession of reversed currents of descending intensity and the curve of magnetisation is re-determined, I find that the two curves differ materially. The demagnetising currents do not reduce the iron to its virgin state. For small forces the second curve is below the first, indicating less induction for the same magnetising force; for medium forces the second curve is above the first, whilst for large forces the two curves agree.

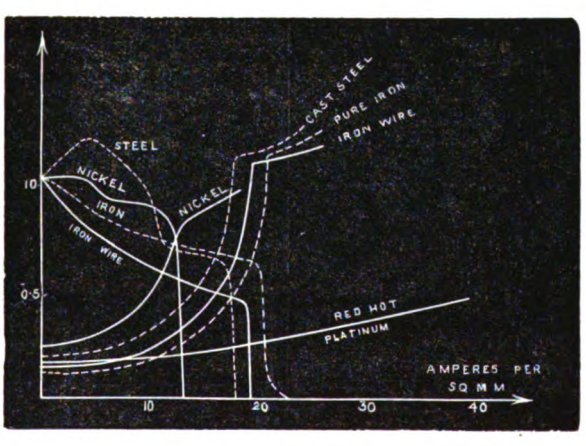


If a ring be heated with a current through the primary coil, and the heating be continued till the ring has ceased to be magnetic, if then the current be stopped and the ring be allowed to cool, I find that the ring is not entirely demagnetised by the heating, but that it re-collects its state of magnetisation before heating. It would seem that the magnetic molecules of the iron, having been directed by the magnetising force whilst they were magnetic, retain in part their direction when they have ceased to be magnetic by heating, and that when they again become magnetic by cooling its effect is apparent.—February 14, 1889.]

I have tested a sample of manganese steel, and find that at no temperature above the normal temperature does it become substantially magnetic.

THE ELECTRIC RESISTANCES AND MAGNETIC PERMEABILITY OF METALS AT HIGH TEMPERATURES.

In the *Annalen der Physik*, N.F., Bd. 33, will be found a short Paper by Prof. Kohlrausch on the relation between magnetic susceptibility and electrical resistance. Wires and strips of iron and nickel were enclosed in an air-tight zinc case, and treated by



passing through them currents of various strengths. The current passing was accurately measured, as was the E.M.F. at their terminals, thus determining the resistance of the wires at various temperatures. The pull exerted on the wire by a powerful electro-magnet of constant strength and at constant distance was also noted. The preceding curves, plotted from the results obtained, show that at that temperature at which permeability suddenly falls there is an equally sudden change in the temperature coefficient. The falling curves are those of permeability, the rising ones those of resistance. In the latter the ordinates for nickel are doubled and the abscissæ for platinum halved.

SOME ELECTRIC LIGHTING CENTRAL STATIONS IN EUROPE, AND THEIR LESSONS.—Part I.*

BY PROF. GEORGE FORBES.

Before commencing the subject of this Paper, I think it may be well if I give you some idea of the reasons why I have brought the subject to your notice. You are aware that great strides are about to be made at the present time in electric lighting in this country, especially by means of the Gaulard and Gibbs system with the converters put in parallel. To complete the practical details of such a system involves a large amount of experiment, and whether low-pressure or high-pressure work is in question, I have frequently maintained that a great deal of experience has still to be bought and time to be wasted. It has appeared to me that we can only hope to ensure the best success of electric lighting schemes now in hand if we bury our pride a little, and try to obtain the experience of foreign countries without paying for it or wasting time over it, as they have done. Some irresponsible persons have considered that I am much to blame for thus advocating the discussion, and consequent approval or disapproval, of systems which have been developed in foreign countries. I do not say that we are not even now capable of doing much better work than these countries, as we have done with steam, and I am certain that we shall do so in the course of time; but I do say that we are wanting in the experience, and I see all over the country work being done where the rules of experience have often been set at defiance; and my object in introducing this subject is chiefly for the second part of the title of the Paper, namely, a discussion of the lessons which can be derived from a study of the work which has been done abroad. The object of this Paper, then, is to raise a discussion on the details of central station lighting and electrical distribution, and to enter a protest against defective systems, which, without some such discussion, I feel sure will be as plentiful in the near future with us as they have been up to the present time.

Of course I am aware that many of my hearers have appreciated these points, and have, like me, tried to learn from those who have had most experience; and I know that they will pardon me for drawing attention to work that they have already examined, since they know as well as I do the need we have for such discussion.

I believe that my object can be best attained by proceeding, first, to describe the principal central stations in Europe which I have lately visited, pointing out specially the features in which they differ from the practice in this country so far as hitherto developed; and then to discuss the details, with a view of deriving the most profitable lessons from them as to what to adopt and what to avoid. I will deal only with what I believe to be the three most important central stations in Europe, namely, Berlin, Rome, and Milan. I have already partially dealt with America elsewhere.†

Berlin is supplied on the low-tension direct-current system, as originally developed by Edison, except the arc lights, which are on a high-pressure direct-current circuit.

Rome is supplied altogether, both for arcs and incandescent, on the Gaulard and Gibbs system, with converters arranged in parallel.

Milan is worked by Thomson-Houston apparatus for arcs, and by both low-pressure currents and high-pressure alternating currents for incandescent lamps.

At all the European stations which I have visited I received the same cordial welcome which I have always had in America, and the same desire that I should thoroughly inspect every part of the works. The stations have literally been placed at my disposal to watch the action of the machinery and to see what attention is required for its management. I have been allowed to interchange dynamos at will and generally to learn all that was possible. I must especially record my thanks to Signor Pouchain, Prof. Mengarini, Signor Trenza, Prof. Colombo, Mr. Lieb, Herr Rathenau, and Herr Datterer for the willingness with which they imparted to me so much information in the details of their working, and to Mr. Zipernowski and Messrs. Ganz and Co. for much valuable information.

BERLIN.

The Berlin mains are at present, I believe, supplying a larger number of lights than any other connected system of mains in

* Paper read before the Institution of Electrical Engineers, February 28, 1888. Part II. has already appeared in our issue of March 8.

† British Association, 1888.

Digitized by Google

Europe. They supply 36,000 lamps of 16 candle-power and 144 arc lamps of 15 amperes. The conductors are all laid underground. A map is shown giving the position of mains already laid down and those in progress of construction. There are three central stations at work, and two more of improved type are in process of construction. The existing stations are—

1. Markgrafen Strasse.
2. Meuer Strasse.
3. Friedrich Strasse.

Those about to be added are—

4. Spandauer Strasse.
5. Schiffbauer Damm.

The first is the most important ; the third is quite unimportant. Here the boilers are by Steinmiller, and anthracite coal is used to

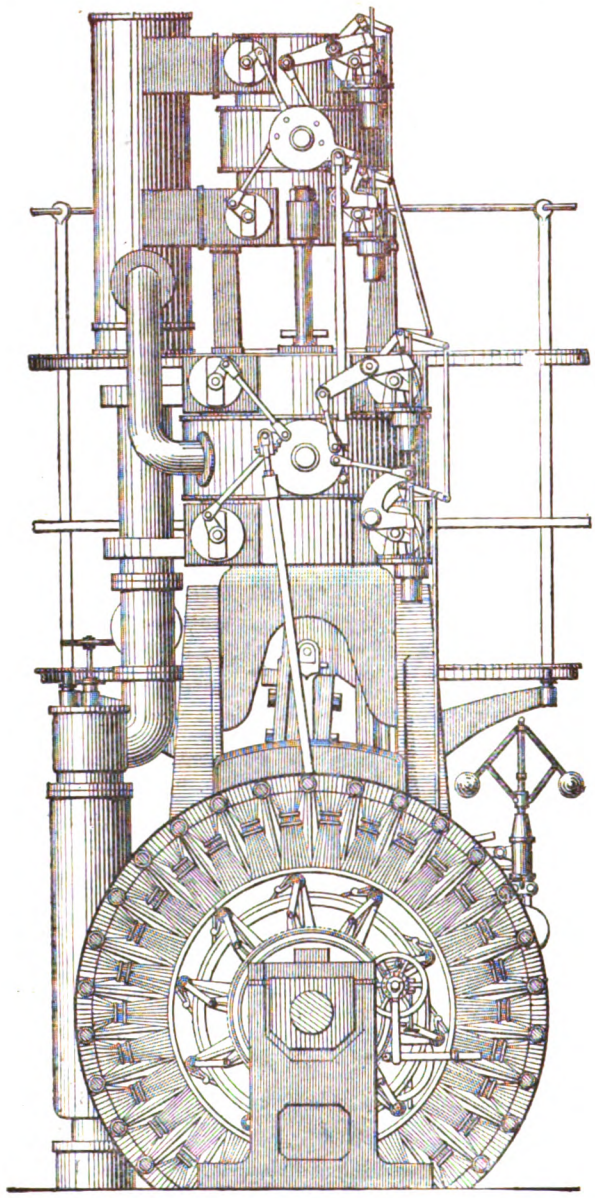


Fig. 1.—Engine and Dynamo, Berlin Central Station. (Scale 1 to 48.)

prevent nuisance from smoke. The foundations are of concrete in iron boxes built up with brickwork and cement. There are six engines of 160 horse-power each, each driving old-fashioned Edison six-legged dynamos. There are also four engines of 400 horse-power each, each driving a new type of dynamo direct at 80 revolutions per minute. These are compound tandem Corliss condensing engines by Van den Kirchove, of Ghent, who is one of the few foreign makers of engines who can compete with this country. The attached dynamos are by Siemens and Halske. The Electric Company of Berlin are also making a machine somewhat similar. A diagram (Fig. 1) is shown of this dynamo and of the engine combined, the height of which is 23ft. These continuous-current dynamos have never been built in this country, and are worthy of some notice. They may be described as multipolar Gramme machines, the poles being radial and the ring armature external to the poles.

There are ten poles on each machine. The armature is 3 metres in diameter, the commutator is 1½ metres in diameter. There are ten brush-holders. Each pair of poles and the corresponding part of the armature, with the corresponding pair of brush-holders, constitute a section which is virtually one machine. All these sections are joined in parallel. The field magnets are not seen in the drawing, being inside the armature. Two handles are provided, one of which adjusts all the brushes at the same time ; the other puts them on all together. Each brush-holder carries four brushes. A similar dynamo is being made by the Berliner Elektricitäts-Werke, in which the radial poles are external to the armature. I believe that this type of multipolar machine is a good design where the object is to get a large output with a slow speed. I hold working drawings in my hand of a similar design prepared by myself in 1881, but it was never executed. The number of bars of the commutator and the number of parts generally make it expensive to construct.

At this station the boilers are fed automatically by means of a hydraulic accumulator. The water for condensing is drawn from fifteen artesian wells which have been sunk for this purpose. Steam is used at a pressure of 115 lb., and it is claimed that 15·5 lb. of steam only are required per electrical horse-power. This is probably the most economical production of electricity for central station work in the world, and the engines and dynamos, though expensive, must certainly have a very low depreciation. The maximum work which this station can do is to generate a current for 26,000 lamps of 16 candle-power. It is found that the maximum number of lamps in use at any one time is about 66 per cent. of the total number of lamps.

The thing which strikes one most in this station is the enormous mass of copper. The conductors inside this station consist of eight strips of copper six inches wide and one-third of an inch thick. These are laid into the room for cable terminals. These strips, before entering this room, are interrupted by a gap, and a junction is made by punching seven similar strips, about 18 inches long, between the strips and the interrupted ends, the seven strips being placed between. Thus, in case of any serious accident, the whole of the mains can by one turn of the screw be disconnected from the dynamos, the interlapping pieces all dropping out. The only exception is in the case of theatres, where to prevent panic a separate connection is made with the dynamos. In the cable terminal room the positive and negative mains run horizontally and vertical rods come down to the different cables. There are eighty-four of these cables, forming forty-two pairs of feeders supplying the network of mains with current on the two-wire system. These cables are generally of large size, being frequently three inches in diameter complete. They consist of stranded cables covered with jute prepared with bituminous compound, enclosed in lead, then covered with tape and preservative compound, and finally armour-plated with two crossed spirals of iron ribbon. The system of feeders and mains is one of the features to which I wish to direct the special attention of English engineers, since the principle has been adopted of trying to produce as small a variation of pressure in the mains as possible. This is accomplished by having a large number of feeders. The cost of the underground cables has hitherto amounted to about £90,000, half of this being spent in mains and half in feeders. The greatest variation of pressure allowed in the mains is 1½ per cent. The loss of pressure in the feeders during periods of maximum supply is 15 volts.

The next point which I wish to draw special attention to in connection with the Berlin central station work is the type of cable which I have now described. This cable succeeded very well for three years, but lately they have been giving way very generally. The lead gets eaten into and water percolates to the copper, which is then destroyed. At first it was supposed that the deterioration came from the cable being pierced by the borers used by the gas people, but it was found that the same fault is produced even in iron pipes which have remained uninjured. It is supposed that the deterioration of the lead may be due in some way to its forming a galvanic element with the iron sheathing. Whatever the cause may be, the fact seems to be established that such cable will not stand underground electric light work for more than about three years. These cables generally run under the footways without any casing, and are connected by circular junction boxes to the houses, powerful clamps and no soldering being used for the contacts. All the dynamos feed direct on to the mains in parallel. One feeder alone, serving the mains close to the station, has a resistance in circuit in the station to equalise its loss of pressure to the others.

A few detached facts strike me as being worth noting.

Each 16 candle-power lamp uses 50 to 55 watts.

The charges for electric supply are 6s. per lamp per annum, and 9·6d. per Board of Trade unit.

The Aron meter is universally employed.

The price of gas in Berlin is 4s. 10d. per 1,000 cubic feet.

Digitized by Google

The distances from central stations to lamps extend to 1,000 or 1,200 yards.

100 kilometres of cable have been laid on the two-wire system.

Each of the large machines can supply 3,000 to 3,500 lamps of 16 candle-power.

The largest cable is 1½ square inches of copper in section.

I spent a long time in this station, and had machines taken off and put on—an operation which occupied two or three minutes. I took careful note of the amount of skilled attention which was required, and saw that it was considerable. A man of high training, accustomed to the use of scientific instruments, is always in attendance and looking after the amperes and volts from the different machines and pilot wires and recording the measurements. It struck me that the working of this station was thoroughly German—certainly not American—but it was most methodical and very effective. One of the most interesting parts of this central station is the switch-board, with the special means for introducing a fresh dynamo in parallel or cutting it out. This also is a point to which sufficient attention has not generally been given in England. In all foreign stations that I have ever seen, when a current of over 100 amperes is switched in or out, it is found necessary to make use of an auxiliary load in the form of resistance, a banks of lamps being generally employed as being the cheapest resistance available. When a new dynamo is going to be introduced in parallel it is first worked on an artificial load, and the exciting current regulated until the volts and amperes agree with those of the other dynamos with which it is to be put in parallel. As soon as this equilibrium is attained the mains are switched into connection with the new dynamo and its load. After that the load is taken off. This prevents the possibility of the dynamo thus introduced being caused to run as a motor in the wrong direction by the current from the other dynamos, and prevents too violent a sparking at its brushes. The switch-board at this central station for the four large dynamos with the accompanying artificial load or resistance and with its ammeters and voltmeters is very perfect. Facing the operator, the switch-board is in four sections for the four dynamos. Each dynamo has three massive double-pole switches—one for the dynamo, one for the artificial resistance, and one for the mains. Plugs can be inserted for varying the resistance on the artificial load. The ammeter is placed above these switches for each machine, and a voltmeter can be attached to any one of them as required. A photograph of this switch-board is reproduced.

The second station is in the Mauer Strasse. This station helps to feed the mains for incandescent lamps. It also supplies arc lights arranged in twelve circuits all arranged in parallel, each circuit having twelve arc lamps of 14 to 15 amperes. Here three Siemens machines of the old type are driven by a counter-shaft. Three Siemens and Halske new-type multipolar machines are also at work, and four Edison machines and six multipolar machines of low tension. 11,000 lamps of 16 candle-power can be supplied besides the arcs.

Sixty-eight feeders, or thirty-four pairs, start from this station.

The Friedrich Strasse station is small, and was the commencement of the present system. Here four six-legged old-type Edison machines, each of 75 horse-power, are driven by Armington-Sims engines, and feed the general system of mains. Fifty-two men are employed on the three stations in eight-hour shifts. The Berliner Elektricitäts Werke paid last year a dividend of 5 per cent.; the Algemeine Elektricitäts Gesellschaft, which does the central station work, paid last year 7½ per cent. In special districts 800 to 900 lamp-hours per annum are used; in residences only 400 to 500 lamp-hours per annum. Load diagrams showing the current used at different hours of the day in each month and the proportionate cost from different causes, fixed and variable, have already been published (see *The Electrician*, June 29, 1888, p. 244).

Milan.

The central station in Milan is not of the highest importance, so far as we can learn anything about it, except on one important point. The principal streets throughout the whole town are lighted by Thomson-Houston arc lights to the number of 350. This lighting gives us some idea of the manner in which this metropolis will soon be lighted; and anyone who sees it and realises that this clear, white, brilliant illumination may be made to brighten our wider thoroughfares and to penetrate our darkest slums, will realise that when London is as far advanced in adapting these possibilities of civilisation as Milan is we shall lead healthier, happier, and purer lives, and our streets will be less notorious throughout the world as the hotbeds of immorality and midnight assassination.

I will briefly refer to the points which struck me as being most worthy of notice.

The station has 14,000 incandescent lamps of 16 candle-power. The maximum load is 60 per cent. of the number of lights installed.

At this station it has been found quite practicable to use Siemens ratchet arc lamps of only 4½ amperes, the upper carbon being 12 millimetres diameter and 200 millimetres long, the lower one 7 millimetres diameter and 200 millimetres long, lasting 7½ to 8 hours. For longer duration larger carbons are used up to 15 hours. This is the first station where I have seen an arc lamp of so low a current in use. A certain resistance is put in series with the lamp, and two lamps are put in series on the mains feeding the Edison lamps.

The La Scala Theatre has 2,800 glow lamps of 16 candles and 30 arcs on the same mains.

Edison meters are used and have given great satisfaction. The price is fixed on a sliding scale varying from 7d. to 1s. per Board of Trade unit. Gas now costs about 6s. 9d. the 1,000 feet. Before the electric light was introduced it was 10s. 6d. the 1,000 feet.

Two of the theatres are supplied by two Zipernowski machines, each of 40 amperes and 2,000 volts. For these circuits Siemens' concentric cables, of which a specimen is exhibited here, are used, the section being 28 square millimetres. Four Thomson-Houston machines are supplying 35 arc lights each, and four more are supplying 30. Half of these are single and half double carbon lamps, the single ones being put out at midnight.

I should mention that the coal used costs 27s. 6d. per ton, but labour is cheap.

Ten Babcock and Wilcox boilers supply the steam. The engines are all non-condensing. The low-pressure system is a two-wire system. Twenty-eight cables, or fourteen pair of feeders, supply current to the mains. No pilot wires are used, but a man reads the ampere-meter and sets the volts by a table. There are ten Edison machines of what is known as the Jumbo type feeding mains on the two-wire system They were originally supplied each with a separate regulator for adjusting the exciting current, but connecting gear has now been introduced which works them all simultaneously. A fan is provided for driving air through holes in the poles of the field magnets. The whole of the low-tension system is antiquated, and we have little to learn from it except what to avoid. I found the arrangements for switching dynamos in and out worked very well. An artificial load of lamps is used at one part of the room, a main going thence past each dynamo. Thus two men are required to put in a new dynamo. It is first put on to the lamps, the machine being excited to the same extent as the other ones. The load of lamps is changed until the volts are the same as on the working circuit. A signal is then given, and the dynamo with its load is switched on to the working mains. The load of lamps is then removed. This is simpler than at Berlin, owing to the fact that the exciting current is known beforehand, but less simple owing to the dynamo switches being distant from the lamps and voltmeters. Ten machines work thus in parallel without trouble, which is a very good performance.

At Milan the average cost for wiring houses is only £1 per lamp. Wages are one-fifth of the total working expenses, coal is one-half, lamp renewals (undertaken by the company) is 7 per cent. The capital is £120,000, of which £24,000 has been spent in mains. The company has paid a dividend for several years. It is steadily increasing, and was 4 per cent. last year. There is a large reserve fund.

(To be continued.)

LEGAL INTELLIGENCE.

United Telephone Company (Limited) v. New Telephone Company (Limited).

This was a motion treated as the trial, the defendants submitting to have a perpetual injunction granted against them restraining them from infringing, as to receiving instruments, Bell's patent, and as to transmitting instruments, Edison's patent, the plaintiffs not pressing for damages. The Attorney-General (Sir R. Webster, Q.C.), Mr. Aston, Q.C., and Mr. Micklem appeared for the plaintiffs; Mr. Bousfield for the defendants.

The ATTORNEY-GENERAL said he wished it to be known that the plaintiffs did not desire to press hard on persons who had purchased infringing instruments, and if such instruments were delivered up within a month the company would not proceed for damages against such purchasers.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

THURSDAY, April 25.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting. "On Lightning Conductors." By Prof. Oliver Lodge, F.R.S. (Member).

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. The Directory was established in 1883, and now makes over 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.

THE DIRECTORY for 1889 is NOW READY.

THE AMALGAMATION OF THE TELEPHONE COMPANIES.

In accordance with the arrangement foreshadowed in our issue of March 22nd, the three leading Telephone Companies have at length come to terms for the amalgamation of their undertakings, and if it obtains the sanction of the Postmaster-General probably the arrangement will quickly include all the minor companies who are still holding aloof. That such a combination was inevitable, or at least would be attempted, became evident from the moment the local telephone service began to develop into long-distance telephony. To be a reality the so-called trunk line service cannot be limited to the areas of several unequal and arbitrary districts, nor can it be interrupted at their boundaries. Working agreements are indispensable, and amalgamation follows in the natural course. Add to this the fact that the present representative of the Government Telegraphs has betrayed a somewhat hostile attitude towards them, the anxiety of the companies to combine for purposes of self defence is both prudent and proper. They are working under license from the Post Office, for which they

Digitized by Google

pay an adequate royalty, and their present position is the natural outcome of privileges freely granted by one of Mr. RAIKES' predecessors in office. Mr. RAIKES evidently does not approve of the conditions, but he cannot repudiate them now; and it would be extremely unfair to cripple the legitimate development of their business simply because the telephone companies have been more enterprising than possibly Mr. FAWCETT ever supposed they would be. The wording of the original agreement reserves to the Post Office, we believe, the right to be consulted on any question of amalgamation among the companies. By giving its consent to the present proposal, the department will stamp with its approval everything that has been done or may be done in the way of trunk line extensions; and for our part we do not see how this consent can be withheld with due regard to the interests of the public, to say nothing of the rights of the companies. Whether they are acting wisely is another matter; but it can hardly be said that they have exceeded their bond.

How rapidly these trunk line extensions are being pushed may be seen from a few authentic details we are able to give in respect to the work now being carried out by the National Company, whose territory extends over the whole of Scotland, and in England includes the Northern and Midland counties as far as Birmingham, with the exception of the two minor sections held by the Lancashire and Cheshire and the Northern District Companies.

The National Telephone Company have recently connected Sheffield with Birmingham through Derby and Burton, taking in Nottingham with a loop on the way; and as Sheffield is in telephonic communication with Bradford, Leeds, Huddersfield, and other Yorkshire towns, Birmingham is thus placed in communication with all these towns. It is also possible to talk through the above system to Manchester and Liverpool. York and Harrogate are connected with Leeds; Skipton and Keighley with Bradford. An exchange has been opened at Grimsby, and the company is intending to connect Grimsby and Goole with Leeds as soon as possible, the work being at present in progress. The town of Hull will be similarly treated. The line between Birmingham and the National Company's boundary towards London is nearly completed, and as great progress has been made by the United Telephone Company with its portion, Birmingham will very soon be in speaking touch of London. It is confidently expected that as soon as the Birmingham line is completed conversation will easily be carried on between the Metropolis and the great manufacturing towns in the North. Manchester will be connected with London by extending the Birmingham-Wolverhampton line through the Potteries district to the Company's boundary, where it will be met by the lines of the Lancashire and Cheshire Company. In the extreme North of England Carlisle and Dumfries are being connected, and before long it may be expected that Dumfries will be linked through Ayr or Galashiels with the whole of the Scotch lines. From Harrogate the company purposes extending its trunk system to Ripon, which is within so small a distance of Stockton that it is not unlikely that the exchanges of the Northern District Telephone Company's system will soon be placed in communication with that of the National Company; whilst there is nothing to prevent Birmingham being coupled up with Worcester and Gloucester, and thus being brought into communication with the system of the Western Counties and South Wales Telephone Company.

Similar progress is being made by the other companies, tending to bring about a complete network of lines, so that uninterrupted communication may be available between them all. To avoid running up unnecessary wires nothing is more essential than that the several companies shall proceed on some united plan which will serve, and not more than serve, the requirements of the districts as a whole. With or without amalgamation this is what they ought to aim at and what they will have to rely upon in estimating their profits from long-distance telephony. It has yet to be demonstrated that long-distance telephony by itself can be made to pay; but it certainly will not pay if broken up into detached fragments. Great expectations are being raised, especially in the financial press, as to the future profits of these extensions, assuming, we suppose, that they will grow to be as widespread and as universal as the inland telegraph system. We shall be much surprised if the companies themselves take that view of their prospects, and they will certainly do well to feel their way cautiously, erecting lines only to such points as will either be directly or indirectly remunerative as feeders or adjuncts of the local services. With the command of the telegraphs to fill up the idle hours, a long-distance telephone wire might be made remunerative at high charges. But the telephone companies do not possess this advantage, and they will probably act with due circumspection accordingly.

In making these observations we have no desire to obtrude our advice on the Telephone Companies unasked for. They ought to know their own business best, and so far it is generally admitted they are performing it to the satisfaction of the community. When, however, we see the organs of finance speaking as if with the authority of the companies, and advising the public to invest their money in telephone shares on grounds which are extravagantly misleading, we may venture to interpose with a word of warning. Telephone shares may or may not be excellent for investment; but on the visionary prospects proclaimed by the trumpeters of the Money Market they would probably prove disappointing. The activity of the companies is taken as meaning so much additional outlay which the Government will be compelled to repay at a high premium. In reality the Government will be compelled to do nothing of the kind; and the best thing the companies can do during their brief period of existence—for they assume that it is to be brief—is to create a property which the Government will be glad to buy and be willing to pay a handsome price for. Still better would it be for the companies if they made the telephone service so complete and perfect in every way that the Government would let it alone altogether, neither buying it nor competing with it. The Government is not obliged to do the former; it is free to do the latter.

THE BOARD OF TRADE INQUIRY ON THE LONDON ELECTRIC LIGHTING PROVISIONAL ORDERS.

This Inquiry has been continued at the Westminster Town Hall since our last report. The following gentlemen represented the various parties concerned:—

Mr. Pember, Q.C., Mr. A. K. Loyd, and Mr. J. C. Graham appeared for the London Electric Supply Corporation; Mr. C. A. Cripps for the Metropolitan Electric Supply Company; Mr. Moulton, Q.C., and Mr. R. S. Wright for the Chelsea Electricity Supply Company; Mr. Muirhead for the St. James's and Pall Mall Electric Light Company; Mr. Roger W. Wallace for the Notting Hill Electric Light Company, for the Kensington and Knightsbridge Electric Lighting Company, and for the Westminster Electric Supply Corporation; Mr. Moulton, Q.C., and Dr. Hunter, M.P., for the Electrical Power Storage Company; Mr. G. Prior Goldney (the City Remembrancer) for the City of London; Mr. T. Percy Gunyon (engineer) and two members of the Council for the London County Council; Mr. C. A. Cripps and Mr. F. M. Jenkins for the Strand District Board of Works; Mr. Hopwood (solicitor) for the Holborn District Board of Works; Mr. E. Bayley (clerk) and Mr. G. W. Thompson (surveyor) for the St. Olave's District Board of Works; Mr. James Spencer for the Greenwich District Board of Works; Mr. J. H. Horton for the Paddington Vestry; Mr. Hitchins for the St. George's (Hanover-square) Vestry; Mr. Wilkins (clerk) and Mr. W. Jenkins (chairman of the Lighting Committee) for the St. James's (Westminster) Vestry; Mr. Webster Murnane (clerk) for the St. Martin's-in-the-Fields Vestry; Mr. T. Eccleston Gibb

Digitized by Google

(clerk) and Prof. Robinson, C.E., for the St. Pancras Vestry; Mr. Cripps and Mr. Greenwell for the Marylebone Vestry; Mr. H. J. Smith (clerk) for the Lambeth Vestry; Mr. Harrison (solicitor) for the Bermondsey Vestry; Mr. E. Moore (solicitor) for the Great Eastern Railway Company; Messrs. Payne, Son and Pollock (solicitors) for the North London Railway Company.

SATURDAY, APRIL 13.

Mr. R. E CROMPTON being recalled and further examined by Mr. MOULTON, said the difficulties met with in practically carrying out underground mains for the distribution of electrical energy are increased in proportion to the E.M.F. employed in the mains, and that whereas in America extended practice has shown that those difficulties are not insurmountable—in fact, are dealt with satisfactorily every day so long as the electrical pressure does not exceed 240 volts; that is to say, the limit of pressure generally employed on the Edison three-wire system—yet these difficulties are so great that they have not been satisfactorily dealt with when the pressure rises to 1,000 volts. He had already stated that the joints are the weak link in the chain of an electric circuit. As the number of the joints is increased the weakness is increased. It will be a matter of extreme difficulty to surmount those difficulties that will arise when 1,000 volts are used, and of course proportionately greater difficulty when 2,400 volts are used. In his own practice at Kensington he did not cut off the electricity in order to make connections—the pressure is kept in the mains constantly day and night. He did not see how it was possible with the high-tension mains for men to work making joints with 1,000 volts pressure on. He had tried all the ways that are known of running mains in pipes, and there are serious difficulties in the way proposed by Mr. Gordon of running several mains into one pipe. He had been obliged to discontinue it in his own case on account of the knotting and crossing of the mains. It is impossible to withdraw one main at a time in the way proposed by Mr. Gordon; it would be necessary to withdraw them as a whole, as the Post Office do with the telegraph wires.

Cross-examined by Mr. PEMBER: If it were necessary to take off the high pressure in the mains to make joints, it could of course be done when there was no working going on, but it would be an inconvenience to those who have the light taken off. He found practically the electric light is such a convenience to people who have dark basements, that they had a certain number of lamps constantly going. He had not been in America, but there was an official document stating that the arc lights with lots of joints in the mains working at 2,000 volts pressure were the reverse of satisfactory. The gentlemen in charge of them report that the cost of "up keep" is so great that they cannot earn a dividend. He had heard Mr. Ferranti's evidence as to the 2,400 volts pressure used at Nancy. Experience was that the trouble with joints only commenced after they had been made for some time. It would take some time to break the insulation down, but given the required conditions it certainly would break down. He believed he was in a fair position to judge of the merits of the transformer system; he was most anxious to be fair to the alternating system. He should unhesitatingly employ it for scattered districts under certain conditions, but for London he had always held the opinion that the concentrated nature of the lighting and the peculiar distribution of the areas of lighting are such as fit it particularly for the direct system employing storage. He had been in transformer stations and seen them working at Salzburg—a large station, rather larger than the Brighton station they had visited yesterday. As to the relative amount of coal consumed on the two systems, he had Mr. Ferranti's figures on the one hand and his own experience on the other, and he had compared them. He had calculated that his own lamps burned 1·1 hours a day. He was aware that Mr. Ferranti's evidence of the consumption of coal on the transformer system was on the supposition that the lamps were burned 10 hours a day; he simply said that was an impossibility—lamps could not burn 10 hours a day. Mr. Ferranti might have based his calculation of the consumption of coal on that 10 hours, but his own idea was that Mr. Ferranti made his calculation in the same way that he (Mr. Crompton) did. He did not think Mr. Ferranti thoroughly explained it in his evidence. Accidents had occurred at Vienna about two years ago, where some burnings-out took place—they were accidents with the direct system. A man put a plug into the wrong bar; the consequence was that although it was protected by what he considered a margin—what Mr. Ferranti would have called a 20 per cent. margin—still there was a good deal of copper thrown about. With regard to depreciation, he had always allowed 15 per cent. for cells in his calculations, but he found it was something less. Eighty per cent. had been the actual average return at the Vienna installations of the quantity generated—that is, deducting loss in the mains and loss of every kind.

Cross-examined by Mr. C. A. CRIPPS: He had no experience of 1,000 volt pressure transformed into 100 volt pressure, but he thought the reduction of pressure reduced the danger very much. He thought with a number of generating stations in comparatively small areas the Metropolitan was the best system, and that the best generating unit is about 200 horse-power. He considered the 2,000 volts in the charging mains the Chelsea were using was safe if kept completely separate from the houses. His experience was that for 100,000 lights of 10 candles 19 tons of coal would be consumed. As to percentage of cost of accumulators, if generating plant cost £200,000 the accumulator plant would cost short of £40,000 of that sum. That would give all the accumulator power he thought necessary—it would be about one-third of the total daily demand. The life of a lamp depends to a considerable extent on the variation in the source of supply, but it has been the case in a good many instances that he had investigated that leaks in the transformer had destroyed the whole of the lamps in one evening. The cost of the distributing mains under his system would be a little more expensive, not much, than they would under the alternating system. He thought it was about as £70 is to £100, taking his own at £100. Taking the absolute cost, the maximum cost of his mains are about £1,700 per mile, the minimum about £900, the largest proportion of the cost being that connected with the earthwork and the shifting of the other pipes and mains found in the line of route. He had actually laid down mains at the cost of £900 per mile—not a whole mile, but he had laid 900 yards at a figure which worked out to that. The average cost, however, was much in excess of that; it had worked up to in some cases £2,000 a mile. It was on the low-pressure system. He laid four miles in Kensington, and the figures he quoted were for representative portions of that. He used quarter-inch section of copper, which for 400 or 500 lamps is the utmost that could be used commercially; if on a short main of, say, two or three hundred yards, a larger number of lamps could be used. The voltage pressure through the quarter square inch for the three-wire system is 240.

Cross-examined by Mr. SHIRESS WILL: He based his condemnation of the alternating system for London on the fact that the cost of placing wires underground will be very great and will cause greatly increased expense. He had satisfied himself that even where it had been worked in England with overhead wires it had been a very costly system. His experience was, however, only second-hand as regards the alternating system. There were three ways in which electricity on the battery system could be supplied. First, a distribution of high-tension current to accumulators in each house; secondly, the distribution of high-tension currents to subsidiary stations, and then low tension from these subsidiary stations; and thirdly, having accumulators at the generating stations and distributing by low tension from those generating stations. The last is not the complete plan at Kensington; it is as Kensington is working now, because it is only on a small scale, but it is being extended to the three-wire system, where two batteries are arranged in series, part of them at home and part at distributing stations; so that it is a sort of intermediate plan between the second and third. The difference in the size of wire to carry 100 volts pressure and 2,000 volts pressure is very great; theoretically, the wire would have to be 400 times larger in the case of the lower pressure, but it is not so in practice. To carry a voltage of 2,000 they would probably put $\frac{1}{2}$ths copper down.

Cross-examined by Mr. WALLACE: The loss of 20 per cent. he had spoken of just before included all the loss—that is to say, the difference between what is generated at the dynamo and what the customers pay for at their own meters. Supposing a system of storage in which the whole current was put into the batteries and discharged, he had not formed an estimate of what the loss would be, but it would be greater than 20 per cent.

Cross-examined by Mr. HEWETT: When before the Special Committee of the Kensington Vestry he did not think the question was put to him as to whether he objected to bring their mains into the same conduit as other companies. Now that it was called to his mind he thought he had objected. He thought it would be necessary to have a subway provided for the four companies in Kensington if there was going to be open competition, but he did not think it would be practicable in High-street, for instance, knowing the small space there was. He did not agree to the small area to be allotted to his company and the Chelsea Company.

Re-examined by Mr. MOULTON: Theoretically, fuses are as perfect a safeguard for electricity as safety-valves are for boilers; theoretically, no boiler or steampipe with a safety-valve ought ever to burst, but as with safety-valves boiler explosions have occurred so with fuses he had seen nasty burns-out. In his opinion there are reliable meters for the direct supply—more reliable than for the alternating supply which have only recently been introduced.

Mr. FRANK KING called, examined by Mr. MOULTON, said he was the chief engineer of the E. P. S. Company, and as such had erected batteries and automatic distributing apparatus in the Chelsea District, the supply obtainable from which was 2,000 10-candle lamps. The batteries are separated into two distinct halves; each half is charged in series from the generating station; while the charge is proceeding to one half the other half is supplying what lamps may be required, and that process goes on until, when the two halves have been fully charged, they are both connected in parallel on to the supply mains to give the maximum output from the storage station. It would be quite impossible for the battery to be both on the charging and discharging main at the same time. The tension in the discharging main is 100 volts. The number of charging mains depends on the number of series; the voltage is 500. The charging main is not broken into at any place throughout the whole of its length. Taking into consideration the economical circumstances in the use of the plant, he believed the comparative waste in the transformer system and in this would be about equal.

Cross-examined by Mr. GRAHAM: There is one generating station in the Chelsea district and three distributing stations immediately proposed. The length of the charging main, which has to bear the tension of 2,000 volts will be about a mile and a quarter. The total current will be 375 amperes. The cells will be in groups of 53, each group giving out 75 amperes. There will be five groups. The weight of each cell is about 2½ cwt. Taking it at 2 cwt., the total weight of the cells would be 26 tons for 1,000 lamps. The cost of each cell erected, with stands and everything complete, is about £5; for 265 cells it would be about £1,325. The batteries can be maintained as things go for a depreciation rate equal to 12½ per cent. The battery at Lloyd's Shipping House, in which the company has a maintenance contract of 10 per cent., actually costs about 4½ per cent. —that has been running for over three years. There are 224 cells—about 400 lights—lighting for about 1,000 hours a year, roughly speaking. With regard to the practice at Chelsea, he had advised the Chelsea Company that they can supply the maximum current for seven hours per day, they having a capacity of ten hours. The depreciation he estimated under the circumstances of working the batteries at Chelsea would be 8 per cent. The positive plates would wear out, say, in three or four years. He had never seen a genuinely worn-out negative plate; he had seen them seven years old, but he would not say they would live for ever.

Cross-examined by Mr. SHIRESS WILL: The Kensington-court station system is not the same as proposed to be used at Chelsea; the system at Vienna more nearly approaches it. The Chelsea Company would require at their sub-station 1,060 cells for 500 lights, taking 20 batteries. He would not be surprised to hear that at Kensington for the same number of lights they only used two batteries. He had heard the light had only been out once in Kensington for three years.

Re-examined by Mr. MOULTON: His company were prepared to take contracts as to the cost of renewals, repairs, and maintenance up to the standard of new at 12½ per cent., which would leave a fair margin of profit. He had made a calculation, and he found they could supply 100,000 lights, or any larger number, at £2. 8s. per lamp running. 100,000 lamps running would be 150,000 lamps installed. The actual capacity of the Chelsea batteries would be 10 hours, and it would be economical with that capacity to work for seven hours.

Examined by Captain CARDEW: Under the Chelsea system they had at each station two distinct halves of batteries, the two halves being capable of working together in parallel at, say, 3 o'clock in the afternoon. They are capable of working together at the maximum supply until 10 o'clock at night.

MONDAY, APRIL 15.

Mr. PEMBER addressed some remarks to the Inspector with reference to the duration of the inquiry. He feared that it was hopeless to think of finishing before Easter.

Major MARINDIN said his inclination was to begin again on the Wednesday following Easter Sunday; but perhaps counsel would consider the matter between then and Wednesday.

Mr. SHOOLBRED, cross-examined by Mr. MOULTON, said that as electrical engineer he had advised many corporations and local authorities, including Bradford, Carlisle, Liverpool, Norwich, Scarborough, &c. He was now carrying out a central station for the Bradford Corporation intended for house-to-house supply, and, after much inquiry and examination of installations, the direct current low-pressure system was decided on. His comparative estimate of cost was slightly in favour of the transformer system—one was £20,000 and the other £19,000, the £19,000 being in favour of the transformer. For the supply of Bradford he considered that the direct system, supplying not merely for light but power, and facilities for storage, was the better suited. When that was extended he considered it would be the most economical to add storage batteries to the system.

Cross-examined by Mr. PEMBER: His previous experience had extended over ten years, including installations at the Forth Bridge and Tate's Sugar Works. Those were for one building, and not brought foward as bearing upon central lighting stations; but the Forth Bridge installation had a considerable analogy with the central station. At the Forth Bridge there were difficult circumstances, constantly changing, much more varying than would be the case with a central lighting station. He had no experience yet of the alternating system. He had taken members of the Bradford Corporation to see the Kensington Court and the Grosvenor Gallery installations, and also the installation at Leamington. At the last there were 2,000 lamps run, a mile and a half of streets being wired. He thought that about 20,000 lamps were run at the Grosvenor Gallery at the time of the visit. The maximum supply from the Bradford machines was 1,800 amperes at 115 volts.

Mr. PEMBER asked for Mr. Shoolbred's Report to the Bradford Corporation, and it was decided to produce it later on.

Cross-examination resumed: The horse-power was 450 in three units, one being intended as a relief.

Mr. WALTER HARRIS KNIGHT (cross-examined by Mr. MOULTON) said he had been an examiner in the United States Patent Office in the class Electricity, and was afterwards with the Brush and Thomson-Houston Companies, and was there in connection with the London Subway Company. The tension used in the transformer system in America was 1,000 volts for the primary circuit. The insurance companies there required the transformers to be outside the houses. The points of inferiority of the transformer system were unreliability and the danger of burning out the transformers, its lack of economy when working on too small a load, and irregularity in the light. The efficiency practically got was 50 per cent.; it could be worked up to 95 per cent. efficiency. He thought it safe enough with 1,000 volts.

Is the shock from 1,000 volts alternating, in your opinion, a dangerous one?—Yes; the primary circuit is, of course, a dangerous one. I have had a friend of mine prostrate with paralysis from getting a shock of 1,000 volts alternating.

WITNESS continued that in his opinion the joining of the mains would be a source of weakness; underground, with high voltage, it was an extremely difficult feat to perform, even when the current was off. He had never known it done with the current on; but with it off it was difficult to get a homogeneity between the insulator that is already down and the insulator to be put in. He had seen the Westinghouse alternating motor and the Thomson-Houston alternating motor, and he had invented one himself, but as a matter of practice it was impossible to get any efficiency worth speaking of, and their durability was extremely uncertain. They burned out under over-load, and they would not respond to the load like the direct-current motor by drawing more current as the speed went down. The Thomson-Houston Company, after spending a deal of money on them, had given them up, and were now more extensively engaged in direct-current motors than anybody else in America. That company was now doing the largest electrical business in America, about equally dividing the alternate current business with the Westinghouse Company, there being an alliance between them. With regard to the working of alternating dynamos for parallel, that had not been practically done in America at all.

Cross-examined by Mr. C. A. CRIPPS: When he was speaking about the lack of economy in the alternating system the generating unit he had in his mind was small—there was none in his country over 100 horse-power. Mr. Young, the gentleman whom he had mentioned as being paralysed, met with that accident by placing his hands on the terminals at the switch-board.

Mr. PEMBER: Was that done with a concentric tube?—No.

Cross-examined by Mr. SHIRESS WILL: Have you had any experience of underground wiring on the alternating-current system?—Not personal experience; I have seen it.

Mr. JAMES SWINBURNE, examined by Mr. R. S. WRIGHT, said that the cost must eventually come upon the consumer if there were several companies in the same district. The effect of "pirate" companies would be very disastrous, because a company like the London or the Metropolitan would, by virtue of choosing all the most paying points in town, be able to undersell, he would say, the Chelsea in Chelsea, and that would hold even although it subjected itself to the compulsory clauses in Chelsea, because it would have such a great advantage in the other parts of London. He thought they would be able to turn their attention to district after district, and starve out every other company in turn. He did not think that electricity was on the same footing as gas when the Gas Acts were passed, because electricity would now have to compete with gas, which had already had its mains everywhere, and there would be no question of monopoly in giving one electric company a district to itself. The competition of gas was sufficient. With overhead wires the alternating system for scattered towns, with a transformer for each house, was a very splendid way of lighting. In Boston electricity was cheaper than gas—gas being 10s. a thousand cubic feet. The direct system was used generally without accumulators, there being some question about the patents. He was very doubtful as to whether the insulation proposed for the Deptford scheme would be perfectly safe; the paraffin wax was liable in time to become full of minute cracks. If electrolytic action commenced it would break down the insulation altogether, and would cause a leak from one side to the other: a leak in a tube with 10,000 volts and 300 amperes or more capable of flowing, might be a very serious thing—it would probably throw melted copper about. The same objections about leakage and loss applied to the Metropolitan as to the London Electric, and there might be troubles of interference with telephones arise from the Deptford scheme. The proposal to earth the main at Deptford gave rise to trouble in many ways. He thought they should not be earthed at the Deptford end. If the telephones were interfered with the Post Office might at any time veto the whole system.

Cross-examined by Mr. PEMBER: He did not like to differ from Sir William Thomson on the point, but he was there to give his opinion.

Mr. THOMAS O. CALLENDER, examined by Mr. R. S. WRIGHT, stated he was the manager of Callender's Bitumen Telegraph and Waterproof Company at Erith. They had manufactured and laid mains for some hundreds of installations. He had had special experience in relation to asphalte paving, and the difficulties of opening, laying, and restoring it. In London, especially the busy parts, all the space under the streets is occupied by gas and water pipes, and the Post Office tubes are running nearly everywhere now. You could not lay your mains close up to gas and water pipes, as the gas and water companies require a sufficient space to be left at the unions in a pipe, so that men can comfortably get their hands and arms down. He thought the proposal of the Metropolitan Company to lay a number of mains in one tube would be a great mistake—there would be very great difficulties when you came to draw them out. His company is a large shareholder in the Chelsea Electricity Supply Company, one of his directors being a director in the Chelsea Company. His company have the contract for the supply and laying the whole of the Chelsea cables. The total amount of the contract is £7,000.

Cross-examined by Mr. GRAHAM: Probably, some part of the payment for the work done by his company for the Chelsea Company would be in shares, perhaps half. As he had said before, he was running 2,000 volts; he had never run 10,000; he did not know anything about 10,000; 2,000 could be quite comfortably worked for charging. He would certainly not use the same sort of cable for 10,000 as for 2,000. He thought 10,000 would be done eventually, but he would not like to do it now.

Mr. J. S. RAWORTH examined by Mr. R. S. WRIGHT, said he was superintending engineer of the Anglo-American Brush Electric Light Corporation, and one of the Committee of Engineers of the Chelsea Electricity Supply Company. The Chelsea Company have erected a building at Draycott-place, 127ft. long by 41ft. 10in., with a basement for engineer and boiler purposes, with two boilers already fixed and working. The ultimate capacity of the station will be 12 or 13 storage stations each of 2,000 10 candle-power lamps. 100 volts; a total capacity of 26,000 lamps in use. On Mr. Crompton's estimate it would be 52,000 lamps fixed, the relation between lamps fixed and lamps used being usually two to one.

Cross-examined by Mr. PEMBER: The Brush Company are large share holders in the Chelsea Company, but he was not aware of the fact sufficiently to justify him in saying that the Chelsea Company is taken over by a syndicate composed of the Brush, the Callender, and the Electric Power Storage Companies. A part of his contract had been paid for in shares of the Chelsea Company.

Cross-examined by Mr. LYTTELTON: The cost of his part of the Chelsea Company's installation, consisting of engines, boilers and dynamos, is £6,500, which is for three battery stations. Some proportion of the amount may be paid in shares at the option of the directors of the Chelsea Company. They can pay all in shares if they like.

Cross-examined by Mr. SHIRESS WILL: They proposed to work entirely from the batteries—that is to say, in the early part of the day they charge up the batteries first one-half and then the other half, then when the heavy part of the lighting comes on, say, at three o'clock or five o'clock or six o'clock, according to the time of the year, they stop the engines and put both the batteries in parallel and work on to the lamps, and that continues during the whole of the night, the engines being stopped absolutely.

Digitized by Google

They would not put down the transformers until they had got to the limit of the working capacity of their batteries, which might be in the course of two or three years. It is a continuous-current transformer.

Major-General C. E. WEBBER, examined by Mr. R. S. WRIGHT, said he was the managing director of the Chelsea Electricity Supply Corporation, and was for nine years division engineer under the General Post Office for the east and south of England, including the metropolis, during which period he had charge of the maintenance of very many miles of underground lines of electrical conductors for the telegraph service. In 1883 he drew up a scheme for electric lighting distribution for the north-east part of the parish of Chelsea. In the same year he patented a system invented by himself of laying large copper conductors in iron cases. In 1884 he and other gentlemen associated with him purchased the present site of the central station in Draycott-place, and formed a company, or rather syndicate, as it was called in those days. In June, 1885, after his return from Egypt, statutory notices were issued for a Provisional Order, the Vestry approving, which was granted by the Board of Trade, and confirmed by Parliament in September, 1886. The original area of supply was in the Hans Ward of Chelsea, and included 660 houses. One calculation has been that about one-third of those will ultimately take the electric light, and that each house will require an average of 27 lamps, making 6,000 in the district, for which they would have to provide 12,000 installed. Under this order we ask leave to add the lower Sloane-street area of about 122 houses. Estimating one-third of these to be consumers it would require 1,080 lamps to be used, or 2,160 to be fixed. Then the Upper Sloane-street division is also applied for with 135 residences, which works out at the same calculation, 44 estimated consumers, 1,190 lamps to be in use, 2,400 roughly to be fixed. Then in the Kensington district, 400 residences, 133 estimated consumers, 7,000 lamps to be fixed, 3,500 in use; and in the area of St. George's, Belgravia, 1,536 houses, 512 estimated consumers, 13,860 lamps in use. As regards the capital, the central station at Draycott place with engines and fitting up will cost about £30,000. The three Chelsea stations proper, Hans Ward, Lower Sloane-street, and Upper Sloane-street together, will cost a further £24,000; Kensington £12,000, and St. George's £42,000. The whole cost comes to something like £108,000, which includes mains and everything. He would like to say that the inhabitants of the district where he lived, in Egerton-gardens, were very anxious to have the light. himself among the number, and a petition had been signed by them to the Board of Trade asking that the recommendation of the Kensington Vestry to grant a license to the Chelsea Company might be carried out as soon as possible, so that they might have the light, and he would propose to put in that petition. Since the Act of 1888 removed the difficulties about the capital, they had found themselves in a position to secure more than the capital necessary for starting the works. The figure of gross earning per lamp, which he had studied in all parts of Europe, varied enormously, but the average earnings of 27 lamps per house would be less than £27—it would be between £20 and £27 gross earning. He calculated that when they were supplying 10,000 lamps in use, running the maximum number at the busiest hour, they ought fairly to earn a net profit of 10 to 12 per cent., available for payment of dividends. There has been no promotion money paid of any kind—no preliminary expenses. Many people put the earnings of a lamp at 20s. year, he put it at about 17s. or 18s. If the London Electric order is passed the effect would be that the Chelsea Company would have a very unwelcome bedfellow, and the streets would be taken up by a second company over that area which Mr. Callender described as being nearly completed with its mains, and it would affect the value of the shares of the Chelsea Company. He had heard what had been suggested by somebody, that several companies should have their mains all in one tube, and that each company should draw out its own main when it was wanted. He thought that was simply folly.

The examination of the witness was not concluded at the adjournment of the inquiry till the next day.

(To be continued.)

BRIGHTON BOARD OF TRADE INQUIRY.

A Board of Trade inquiry with regard to the application of the Brighton Electric Lighting Company for a Provisional Order was commenced at Brighton on Thursday last by Major Marindin, C.M.G., R.E. Mr. F. J. Tillstone (Town Clerk), Mr. Lockwood (Consulting Engineer), and Mr. Boxall appeared on behalf of the Brighton Corporation; Mr. Roger W. Wallace appeared for the Hove Commissioners; Mr. J. W. Howlett represented the interests of the Brighton and Hove Gas Company; and Mr. Shiress Will, Q.C., represented the promoters of the Company.

Mr. WILLS, Q.C., said that he represented a company who had been for several years past supplying electricity in Brighton, and he thought they would be satisfied that considering the limited powers they had and the necessarily limited nature of their operations and of their works, they had been doing so with great advantage to the town. A number of private houses and hotels, he said, were being supplied, and generally it would appear that satisfaction had been given. Objections had recently been made to the overhead wires, and a Board of Trade inspection was held by Colonel Armstrong. After referring to the report of the examination made at that time, counsel stated that it was recommended that application should be made to the Board of Trade for a Provisional Order, so that the company might have power to carry their lines underground. A letter had been received from the Board of Trade on the subject and application had been made. He was sorry, however, to state that they had not been able to gain the consent of the Brighton Corporation nor of the Hove Commissioners, but he hoped nevertheless to be able to satisfy them on that occasion. Allusion was next made to the obtaining of a Provisional Order by the Brighton Corporation for the supply of electric light in a specified area as was shown on Schedule A, and which did not cover the whole of Brighton. Without entering into any controversy as to the reason why the Corporation scheme was not carried out, he would say that they had done nothing towards lighting that compulsory area. They had it, he understood, in the Pavilion and several other places, but not in the area for which the order was applied for. He took it that the Brighton Corporation had been very anxious to be careful with the ratepayers' money, and rightly or wrongly they had taken the view that the system of electric lighting was of an experimental character. Continuing, he assured those present that the company he represented desired no monopoly, and observed that the order they wished to apply for would provide that all new mains should be laid underground. Further, they asked for five years in which to remove the overhead wires, and he hoped after the evidence had been given that they would be better able to judge of the matter. Another thing he wished to call attention to was that they were not bound to have any particular system supplied, and they would be free to adopt as a company any system which science might prove advantageous both for commercial and other purposes. The objections of the Hove Commissioners were almost confined to the clause stating "that the description of the proposed works was insufficient, and the provisions for securing the safety of the consumer and of the public inadequate," but in answer to that he would say that the company were under the orders of the Board of Trade from time to time. The objections of the Gas Company principally had regard to clauses 11 and 12, but in those clauses the company were following the forms authorised by the Board of Trade. As to the Telephone Company their objections had been met. After a lapse of seven years the Electric Light Company would be prepared to bind themselves to a standard price fixed on a sliding scale as in all new gas companies. They wished to act in a fair commercial spirit, knowing that in satisfying the town they were considering their own interests. Mr. Wills then called

Mr. ROBERT HAMMOND, the Chairman of the Brighton and Hove Electric Light Company, who said that he had been chairman of the company since it was started in September, 1885. The company on its formation took over an existing concern, which had been going for about four years previously. House-to-house electric lighting had therefore existed in Brighton since 1881. The company had supplied electricity by means of overhead wires, and had been prepared wherever way leaves were obtainable to supply electricity in Brighton and Hove for house-lighting, hotel-lighting, or any other purpose. The company had lighted the station during the whole time. Up to the present the Brighton Company had no powers to lay wires underground, but they desired to have them, as they believed that they could greatly improve the lighting if they had them. There were over twenty miles of overhead wires in Brighton, the area in which they existed being bounded by King's-gardens, Hove, on the west, Belgrave-place, Kemp Town, on the east, and Hanover-crescent on the north. The station of the company was in Gloucester-road. They received a letter from the Board of Trade on November 6, enclosing a report by Colonel Armstrong, asking whether the directors were prepared to take the necessary steps to comply with his suggestions, and calling the attention of the directors to the serious responsibility they incurred by supplying electricity under the system described in the report. The main objection raised by Colonel Armstrong to their system of overhead wires was that they were not covered with proper insulating material, and in certain places they were not running parallel, and therefore did damage to the Telephone Company's wires by induction. On receipt of that letter and report, the directors at once placed themselves in communication with the solicitors of the Telephone Company, and agreed that they would change their wires in such a way as not to interfere with the telephone wires. They entirely removed the objection, and the Telephone Company sent a cheque the other day for a portion of the cost, and expressed great satisfaction with the present state of things. In giving five years as the period they would take in converting the overhead wires to underground they had adopted the extreme time, and would undertake to make the change in three years. The company desired to run the wires underground because they could use cables of a thickness that they could not run overhead. They would be able to give better light and to regulate it better. Their price during the last few years had been 1s. per Board of Trade unit. With the very large increase of plant which this order would enable them to put down they saw their way to a great reduction in price, and they proposed to base their prices on the consumption, according to a sliding scale of 1s. per unit, 9d. per unit, and 6d. per unit, so that clubs, hotels, and large consumers would get their electricity at something like 7d. per unit. Where the light was required over three hours a night it would be supplied on the sixpenny scale, or at an alternative charge of 8d. per unit all round; 6d. per unit was equivalent to about 4s. in gas. The company were not asking for any monopoly, and were making their application in full knowledge that the Corporation had their Provisional Order of 1883. They proposed to limit the dividend after seven years; they said seven years, because with the present limited number of electric light supply companies in the country it was impossible to fix a fair price, but the experience of seven years, they thought, would enable them to determine. At the end of seven years, under the order, the price would be fixed by arbitration based on a 10 per cent. dividend, power being given them to increase that dividend with every reduction in price. The system now in use by the company was the alternating-current parallel transformer, which he had found to work well, not only in Brighton but in Eastbourne and Kensington as well. The Brighton Company had so far paid. Their standing charges had been enormous compared with what they would be if they had a larger plant and could supply a larger number of people. The same electrician could manage a place five or ten times as big as the present station. Notwithstanding these disadvantages, they were the only Electric Light Supply Company in England that had regularly paid its shareholders from the beginning and put aside a sufficient

Digitized by Google

reserve for depreciation. Before the company was formed an immense amount of money was spent in experiments, and this did not appear in the balance-sheet. They had occasionally received congratulatory letters from customers.

Mr. WALLACE: I think perhaps it would be as well if Mr. Hammond put in the letters of complaint as well.

Mr. HAMMOND: I haven't those with me. Proceeding, Mr. Hammond said they admitted that their light had not been perfect, but any defect was due to their works being so cramped. The demand in Brighton for electricity was increasing, and the average increase in their business on the year was 41 per cent. The increase on the quarter just ended, as compared with the corresponding quarter of last year, was 81 per cent. Up to the present they had been able to cope with the demand, but could not put down any more machinery.

Cross-examined by Mr. BOXALL, witness said that there was no provision in their Provisional Order for the appropriation of any specific sum by way of capital, nor was there provision for any deposit, but they would be pleased to put in clauses to that effect, and also a clause for revocation in case the capital was not subscribed in a certain time. Up to January of this year the nominal capital of the company was £25,000, but only £12,500 had been actually issued, and £3,100 of that was issued during 1888. Up to the end of 1887 they had fifteen miles of mains open, and they added over five miles during 1888. They gave notice of their intention to apply for a Provisional Order so far back as June, 1888, and, notwithstanding that they contemplated the application, they continued to increase their overhead mains, as they were not certain of the application being granted. By the Provisional Order they would be compelled to put all their present circuit underground during three years. The undertaking taken over on the formation of the present company was the Hammond Electric Light Company. He did not know at what amount the works of that company were put down in the liquidation. His impression was that the works cost £10,000. When that company went into liquidation he and others bought the Brighton branch for £2,000, and re-valued it at £6,000 in issuing shares, as in the meantime they considered they had spent £4,000 upon experiments in connection with it. Out of their profits the company kept the plant in repair, but they allowed 5 per cent. in addition for depreciation. If they allowed 7½ per cent. it would take away half the dividend paid during the past year. £212 was spent in repairs during 1888, but that did not come out of the £3,100 additional capital raised. The £3,100 was mixed with the other monies, and drawn upon for repairs.

Mr. BOXALL: Then that is another £212 to come off your profit. The rest of your profit is entirely made up from wiring new premises.

The witness said that they made a profit of about £360 in wiring new premises. He had not calculated the mileage of streets in the area they proposed to supply, nor did he know the number of houses in the area. They had calculated that if they put down plant capable of supplying 12,000 lights they would be able to meet the demands made upon them during the first year, and they would be prepared to increase their plant as the demand increased. The witness admitted that he had been connected with one company that went into liquidation, and in a sub-company he lost £12,000, but said no supply company he had started had been unsuccessful. He named the Brighton Company and the Hastings Company as instances of successful companies. The Hastings Company was started at about the same time as the Brighton, and paid a dividend last year of 3 per cent. The Eastbourne Company had not paid any dividend, but it had been a very successful company. He had not calculated what the cost of converting twenty miles of overhead mains into underground mains would be. They proposed to appropriate £25,000 of capital, but they would call up their capital as demands came upon them. They had a distinct plan for a new station, but they had not bought the land for it, and he declined to mention the site they had in view. They would be willing to deposit £2,000. He would be willing to have a clause revoking the powers given by the order unless the whole of the capital was allocated and £50,000 subscribed within two years. He should not be willing to limit the area. He was willing to meet the Corporation as to the length of notices.

Cross-examined by Mr. HOWLETT, the witness said he was not aware that there had been great difficulty occasioned to the Gas Company at Eastbourne by the Electric Light Company's work, and he was not aware of any complaints being made by the Gas Company. He had never heard of anything spoken of in the following paragraph:—"There is scarcely a day that the electric light people are not at work in some part of the town repairing their cables, and in many instances their mains have been run in the soft ground of the Gas Company's mains, and in some places between the Gas Company's mains and the kerbs, so that it is very awkward for the Gas Company's men to drill their gas mains for new service pipes." It was their intention to lay mains in every street in Brighton and Hove if the electric light was demanded.

Re-examined, the witness said that the company had not chosen the persons whom they had supplied, but had supplied everyone who had applied to them.

Mr. ARTHUR WRIGHT was next called, and, in answer to Mr. WILLS, said he was an engineer of the company and had been connected with it since 1881. From his experience of electric lighting he was of opinion that the electric light in Brighton and Hove was not in an experimental state, but that it was in a practical commercial stage. The system which had been supplied had been practically convenient for the town. They had tried three systems, and he agreed with Mr. Hammond that the company were not tied to any system. The company's plant had been duplicated lately in order to provide against any breakdown. He understood the Hove Commissioners thought electric lighting not sufficiently advanced to be supplied. He considered that Brighton was well suited for the accommodation of electric light; in fact, with the exception of London, better than any town in England. There was no difficulty in supplying it underground, nor in relation to metering the electrical currents. In his estimation the price proposed by the company was not exorbitant; in fact, it was too reasonable. At any rate, it was not hard on the consumer.

Cross-examined by Mr. BOXALL: They had received complaints. The system now in force had been adopted since last July.

Cross-examined by Mr. WALLACE: With overhead wires it was very difficult to distribute electricity. During the year 1888 14,910 units were supplied.

Re-examined by Mr. WILLS: The present sliding scale came into operation on January 1st, and it was, he believed, a non-paying concern on the present basis. That was done to encourage consumption. There was no doubt that in making a larger supply they could do it more economically.

Mr. WILLIAM LOWRIE, engineer of the company at Kensington, said he understood he was to be constructing engineer to the Brighton Company should they get the powers they desired. He was the engineer to Messrs. Hammond and Co., and had charge of the construction of new works at Eastbourne. He had nothing to do with the management. The contract at Eastbourne had been carried out to the satisfaction of the Corporation. He understood that it was intended to substitute underground mains for overhead, and he saw no difficulty in carrying it out. The cost of the change must depend upon the district. For a thousand lights per mile he should say that the cost would be about £400 per mile for conduits. He should think that the company would find it to its interest to adopt the underground mains.

Cross-examined by Mr. BOXALL, the witness said he was consulting engineer to the Eastbourne Company. The mains and service pipes at Eastbourne were all underground. They were put underground without the assistance of a Provisional Order. The mains were also underground at Hastings, having been put under without the assistance of a Provisional Order. At West Brompton they supplied about 500 lights. The cost of the mains and laying them would average about £800 a mile. No difficulty was experienced in finding places to put their mains in the streets at Hastings and Eastbourne.

Cross-examined by Mr. WALLACE, the witness stated that the cost of producing electricity at Brompton under the system in existence at Brighton was 3½d. to 4d. per unit. Under the pavements he would not require to go to a greater depth than six inches in laying mains.

Cross-examined by Mr. HOWLETT, the witness said that it was not true that scarcely a day passed that the electric light people at Eastbourne were not at work in some part of the town repairing their cables. It was true, however, that they had a fair amount of repairs to do at Eastbourne. The first cables were put down at a time when little was known of electric lighting and were very faulty. The cables put down under the alternating system had not been repaired.

Re-examined: They had power at Kensington to supply 6,000 lights, although at present they only supplied 500.

Major-General KENYON STOWE, 31, Brunswick-terrace, Hove, said he had had an installation in his house from the Brighton Company for about a year. There were nineteen lights. He had no complaints to make except with regard to a slight bobbing up and down when they turned out the Alhambra lights. He would not be without it under any consideration.

Cross-examined by Mr. WALLACE: He did not care from whom he got the light as long as he got it.

Mr. LUNDY, manager of the Brighton Alhambra, said that they had about 300 lamps, which were supplied by the Brighton Electric Light Company. The lamps gave a splendid light, and it was of great advantage to them. He had seen the electric light at the Empire and Pavilion in London, near the Grosvenor Gallery, and elsewhere, and the Brighton light was the best he had seen at a place of public entertainment. He thought it would be a public advantage for the company to obtain the powers they sought and supply the town.

Cross-examined by Mr. BOXALL: He could not say that the directors of the Alhambra were intending to discontinue with the Brighton Company and obtain their light from London. If that were so he thought it would be on account of cost rather than the quality of the light.

Mr. PEAKE, 16, Belgrave-place, Kemp Town, said he had seven lights supplied by the Brighton Company, and he found it excellent in every way. The previous night, thinking he was coming to the inquiry, he put himself in the main circuit, and there were no ill effects whatever.

Prof. GEORGE FORBES said he was of opinion that the electric light was not by any means in an experimental stage. It was admirably adapted for house-to-house lighting. He did not think the company would have any difficulty in insulating 2,000 volts, or that any difficulty would arise in continuity of lighting.

Cross-examined by Mr. WALLACE: There was really little work done in England in regard to the system proposed to be adopted in Brighton by the company. He knew it was very largely adopted in some other countries. In his opinion the number of central stations on the alternating-system exceeded those on the direct plan. He would not speak positively that such was the case. He considered Hove was not suited for a battery station.

Mr. GEORGE HECKBURN, manager of the Bedford Hotel, Brighton, stated that the hotel had an installation from the company, and he found it had worked very satisfactorily, and the customers liked it. During the last two months he had made a calculation and found it came to a 1¼d. per light per night.

Mr. ALFRED ROGERS, an estate agent, said that since Monday afternoon last 2,996 signatures had been obtained from all classes of society in Brighton and Hove in favour of the electric light, and a petition had been prepared to the effect that the electric light would be most welcome, and hoping that the Provisional Order would be obtained by the Brighton and Hove Electric Light Company in order to do away with the objectionable practice of having overhead wires.

At this point the inquiry was adjourned.

Digitized by Google

FRIDAY, APRIL 12.

On the resumption of the inquiry, ROBERT REED was first called, and said he went round with a petition in Over-street, Brighton, for the purpose of canvassing.

Mr. WILLS, Q.C., intimated that he had 1,900 other signatures that morning.

This closed the case on behalf of the company.

Mr. BOXALL then addressed Major Marindin on behalf of the Brighton Corporation, and stated that the company came forward asking for a Provisional Order to supply an area where the local authority withheld its consent, and when such an authority was itself armed with an order to supply the district or a part of it if they thought it desirable. Mr. Boxall characterised it as a remarkable application that they desired to supply a very wide area with a very small capital. They had come before them without any figures and without any calculations indicating what the expenses of supply to the area which had been named would be and what the requirements of the area actually were. They did not disclose any prospect of financial success, they did not attempt to show—and he submitted if they had they had absolutely failed—that it could be a paying concern and as to whether it would be likely to return a dividend. They came there but did not inform them that they had made any attempt to obtain the leave of the Corporation for laying mains underground, as it was alleged they had succeeded in doing at Eastbourne and Hastings. On the contrary, what they had done there had been to put down—as they had informed them—over twenty miles of overhead mains. They had got before them the report of the Government inspector showing that those overhead mains were not properly insulated and were insecure and unsafe. He did not see why they should accord them exceptional assistance by means of that order, entitling them for 42 years to have what was practically a monopoly supply of electric lighting in the town, which would authorise at least three years wherewith to maintain the present unsafe system of overhead mains and give them the power of breaking up and interfering with the streets and roads, which were vested in the local authority whom he represented and whom his friend (Mr. Wallace) represented. All these rights they were to have because they had already raised up in position unsafe overhead wires. He submitted that if that were taken as a reason and they were to have those advantages it would be a most unfortunate precedent; and with no other inquiries which were likely to take place it would be open for the persons promoting the company to get very large subscriptions from the public, knowing how easily they (the public) were attracted to anything in the shape of statutory authority. It would be a temptation to such undertakers to commence with a very small system and a very small capital in the various towns and in defiance of the local authorities by commencing overhead mains, and then they would go to the Board of Trade to get power to break up the streets and roads. The Brighton Electric Lighting Company started under exceptionally favourable circumstances, obtaining their premises, plant, and works at an enormous discount on the original cost, having the able management of Mr. Hammond as chairman and Mr. Wright as manager, and yet they were only able in the third year to show a dividend of 5 per cent. But when they came to analyse the balance-sheet they found that only 5 per cent. had been allowed for depreciation, and that a profit of £532 included £357 from wiring new premises, which could not be expected to continue. Mr. Boxall submitted that 7½d. per cent. at least should be allowed for depreciation, and if they allowed that and the £357 were deducted from the profit, instead of a profit the balance-sheet would show a deficit of £100. This deficit was made under favourable circumstances, when higher prices were being charged than the maximum prices authorised by the draft Provisional Order, and the manager had himself told them that with the prices now charged the electricity must be supplied at a loss. What prospect was there then of the company being successful? Then on Mr. Lowrie's estimate the cost of placing the twenty miles of overhead wires underground would be £16,000. How could they expect to pay a dividend? This was a matter of great importance to the Corporation, and they had a right to ask, "Is this going to be a permanent supply to Brighton, or is it only going to be a sale of a valuable concession to a number of shareholders upon an increased capital and then a liquidation, or a user for the term of three years of the overhead wires without any honest attempt to replace them by underground mains—a profitable user during that time and then a break up, perhaps, of the company?" For he submitted that for three years neither the Corporation nor any inhabitant of the borough could require the company to lay a main, and therefore, unless the company was to be permanent the powers they took were all to their advantage. The Corporation had themselves power to supply electricity, and intended to do so when they thought the time had arrived when they could do so with advantage to the community. He also called attention to the large number of pipes already under the streets, the narrowness of the streets, and the great inconvenience that would be caused by the company having the power to break up the roads, and, putting the objections briefly, said that the Corporation opposed the granting of the order not only because they thought the company financially insecure and because in detail its scheme was unworkable, but because it would have a right to interfere with their property.

Mr. LOCKWOOD, late borough surveyor and now consulting engineer to the Brighton Corporation, was examined by Mr. BOXALL, and said that in 1883 a Provisional Order was obtained, and in that year the Town Council caused a permanent installation of 500 lights, at a cost of £2,700, to be placed in the Royal Pavilion. In the following year, 1884, a further installation of 400 lights was added, which extended to the public buildings, such as the Assembly Room, the Free Library, &c., making the total installation 900, the total cost of which was £5,045. In 1887 it was found that the insulation of the installation was imperfect, and under the direction of Mr. Preece—who was that day unable to be present through indisposition—the mains were relaid at a further cost of £500. It was now in working order. The Brighton Corporation had a very good place a mile away for placing a station in case of the electric light being adopted. It was near the waterworks.

Cross-examined by Mr. WILLS: He could not say how long the Brighton Corporation would be before adopting the electric light. He was of opinion it was very much better that the powers of electricity should be in the hands of the local authority.

The Hon. REGINALD BROUGHAM (examined by Mr. BOXALL) said that he was electrical adviser to the Corporation. His experience with regard to the laying of mains for the electric light was confined to London; but they laid down a main through Chelsea about six weeks ago. The street in which they laid it was a very open street—such a street as Mr. Lockwood would call a clear run—and there were a great many reasons for getting the work done as quickly as possible, but though he had 160 men on they were ten days in doing 1,200 yards. He had no experience with regard to the cost of laying the mains except in London, and therefore he was prepared to take Mr. Lowrie's figures of £800 per mile for a thousand lights. He should say, however, that Mr. Lowrie had erred on the side of economy rather than extravagance. For the proper supplying of a place they generally calculated one light per head of the population. Perhaps 100,000 lights would be sufficient for Brighton exclusive of Hove. They could not possibly, he thought, put down the plant under a cost of £2 per light. That was for the installation buildings, &c. It did not include mains. For 100,000 lights this would come to £200,000. Then there were the mains. There were 72 miles of street in the borough, and though a main was not required in every street, mains carrying more than a thousand lights were necessary in some streets, so that it would be fair to estimate 50 miles of mains. Fifty miles at Mr. Lowrie's estimate of £800 per mile would come to £40,000. Thus the plant, &c., for properly supplying the whole of Brighton with the electric light would amount to £240,000. Such an installation would entail a large amount of coal, and it would be inconvenient to have the plant in the town itself; it would be much better to have it outside the area. In his opinion 5 per cent. was not sufficient to allow for depreciation of premises, plant, and circuit. The overhead wires would depreciate to the extent of from 10 to 12 per cent. Five per cent. was a sufficient amount on the engines, providing they were properly looked after, and 6 per cent. would be a fair amount to allow on the dynamo. He thought an allowance of 7½ per cent. all round would be about right.

Cross-examined by Mr. WILLS: He had been an engineer all his life. He was a director of the London Electric Light Company and of the Grosvenor Gallery Company. The Grosvenor Gallery Company was sold to a large company, but it had not paid a dividend.

Mr. WALLACE, in addressing the Inspector on behalf of the Hove Commissioners, said it was a rather peculiar district compared with other towns in that it was extremely regularly laid out and contained a very superior class of houses. The town of Hove was governed by Commissioners, a body of men who were well able to give their attention to the matter, and had a good deal of time on their hands. They had given considerable time and attention to the various systems of electric lighting, but up to the present time they did not feel altogether justified in adopting any particular system. They came before him to oppose the Provisional Order applied for by Mr. Hammond's company. The Hove Commissioners did not wish to criticise the efforts which had been made to obtain the order to supply electric light to Brighton, but they declined to give their consent on the ground that the time was not a right and proper one for the supply of electric light to the town of Hove, and when such was wanted the Commissioners were the proper persons to choose the best system, and they could, moreover, find the capital for it. They had appointed two of their Commissioners as a sub-committee to investigate the various systems, not only of the company of the promoters of that order but also other systems in various parts of England. The results of their investigations had been that there were other systems which were considered to be much better than that proposed by Mr. Hammond.

The witnesses were then called on behalf of the Hove Commissioners.

Mr. G. B. WOODRUFF, the Chairman of the Works Committee of the Hove Commissioners, said he was formerly for many years a civil and mechanical engineer. He was familiar with the requirements of Hove, having been six years a member of the Commission and three years Chairman of the Works Committee. Up to the present there had been very little demand for the electric light. There were only ten houses which had it laid on, but there might be a few more who wished to take it. Those who had it were not entirely satisfied with it on account of the flickering. He certainly thought that some form of storage was desirable. He knew of no machinery that could be relied upon. They found in all the works they visited that the machines sometimes broke down. Hove was purely a residential neighbourhood, and the noise of machinery at night would be very objectionable. He had made calculations as to the cost of various systems, and found that economy was to be found in some system of storage. The Hove Commissioners were not against electric lighting in itself, and they hoped in time to light the town themselves. In a few months they hoped to secure a good system. He considered that the company's system of putting street mains would be thoroughly bad for Hove. Their mains were large and cumbersome, and the Commissioners objected to their being laid under the carriage way. The Works Committee had in mind suitable sites for erecting works.

Cross-examined, WITNESS said that in his opinion the town of Hove ought to have a Provisional Order or license to do the work themselves Having that order, it was open to them to contract with any good company they chose. The Commissioners would not desire to have several companies operating at one time in the town, and he objected to two companies competing to supply the town. The Hove Commissioners, he thought, would be able to supply the light cheaper than the company, because there was the Town Hall and public streets which they could supply, and there were systems which could supply electricity at a much

Digitized by Google

cheaper rate than the system of the Brighton company. Since January 24, when the report was adopted by the Commissioners, witness had obtained information with regard to the different systems of electric lighting from Mr. Henry Edmunds, Mr. Sayers of Chelsea, Mr. Crompton, Mr. King (the electrical engineer to the Electric Power Storage Company), and he thought he might add Mr. Wright and Mr. Lowrie, though he could not say whether he had seen Mr. Lowrie since January 24. He had made up his mind that some form of storage was the system for Hove. The Commissioners had not passed a formal resolution in favour of the Brush system.

Re-examined, WITNESS said that he read all the scientific works and reports of engineers on the subject as they appeared.

In answer to the Inspector, the WITNESS said he could not say definitely that the Commissioners were going for a Provisional Order, because they had not passed a resolution to that effect, but knowing the feeling of the Commissioners generally he believed they would apply for one.

Mr. H. H. SCOTT, Borough Surveyor at Hove, examined by Mr. WALLACE, said there would be difficulties to be overcome in laying down the mains under the pavements, in consequence of cellars and other matters.

Mr. R. E. CROMPTON, Managing Director of "Crompton and Co.," spoke of his experience with regard to the carrying out of large central stations both in England and on the Continent. He had examined the station of the company at Brighton, and considered that under that system there were no known means in this country for supplying motive power.

Cross-examined: He was an advocate for the battery system. He made the plant for both systems. He made converters for towns in South Africa and Australia. He should think the accumulator system preferable for Brighton. He was not aware that Viscount Torrington, the chairman of his company, had written to the Corporation asking to be allowed to light the town with electricity, though he knew he was exerting himself in Brighton. He should advise several subsidiary stations for Hove, charged as in the cases of Darmstadt and Vienna. The Brighton Electric Company might apply the battery system, but a large portion of the original capital would have to be spent in distribution on the original system. By that he meant that the mains in the streets would not be useful in the battery system because the section of copper utilised would be too small.

Mr. J. W. HOWLETT, who appeared on behalf of the Brighton and Hove Gas Company, stated that they had objections to Clauses 11 and 12.

The INSPECTOR suggested that any alterations which it might be deemed advisable to make by the Brighton and Hove Gas Company might be made in writing and directed to him and be presented to the Board of Trade as amended.

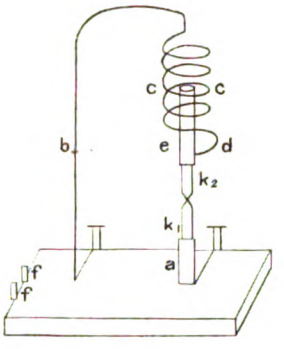
With this Mr. HOWLETT acquiesced.

Mr. WILLS, replying on behalf of the company, contended that the petitions which had been handed in were of some substantial value. They had not so much to consider whether they were the very best company in the world, or whether the Brighton Corporation was the worst, but simply to judge as to whether the interests of the community would be enhanced. He pointed out the special circumstances of the case before them, and alleged that although the Brighton Corporation had had a Provisional Order for supplying electricity since 1883, yet not a step of any importance had been taken. It had been a "dead letter" to the present day. He contended that the company whom he represented had been giving satisfaction to their customers, and he had no doubt they would continue to do so with increased powers given them. Notwithstanding the very able and exhaustive speech of Mr. Boxall, he never put a single member of the Corporation into the box to say that the company was not to be trusted, or ought not to have the Order they asked for. The Town Clerk had been present throughout the inquiry, but had not been brought forward to say that it was not in the interest of the Corporation that the powers should be granted to the company, or that there were complaints against the company. Proceeding to consider the grounds of opposition, Mr. Wills said he quite acknowledged the propriety of the Corporation using all fair efforts to see that they were not prejudiced, and to require to be satisfied on matters of finance, but he adhered to his offer to make a deposit of £2,000, and to subscribe such capital as the Board of Trade should require. That would give security to the community, and give the company a great interest to do the work efficiently, cheaply, and well. As to site, any new station should be subject to the approval of the Board of Trade. He would agree that the prices should not be increased after seven years, and as to the company's prices prejudicing those of the Corporation, the Corporation could easily go to the Board of Trade and get another Provisional Order so as to raise their charges. But the great objection, both of the Corporation and the Commissioners, seemed to be that house-to-house electric lighting was still in an experimental stage. He had called eminent witnesses, however, to disprove that, and even Mr. Brougham, one of the witnesses for the Corporation, admitted that for two years it had been beyond the experimental stage. As to the Commissioners, Mr. Woodruff could not say that they would go for an order; and suppose they did, what guarantee was there that they would use it, or that the ratepayers would allow them to spend the requisite money on plant. Surely it was far better to let the company run the risk, which they were willing to run, and to supply the place. With regard to the system, Mr. Wills submitted that he had called evidence to show that the transformer was the best, but the order tied the company down to no system. If the order were granted the company would bind themselves to proceed with all reasonable despatch in replacing the overhead wires with underground to the satisfaction of the Board of Trade, and would agree that the deposit should not be released until the work was done, or that if within a year after the order a third of the work was not done a third of the deposit should be forfeited; or they were willing that the three years should be reduced in any way the Board of Trade might think fit. As to Mr. Howlett, he was afraid all he could say in the way of consolation to him was that they would give him every protection the Board of Trade allowed to other gas companies elsewhere.

At the conclusion of Mr. Wills's remarks the inquiry terminated.

AN ARC LAMP FOR AMATEURS.

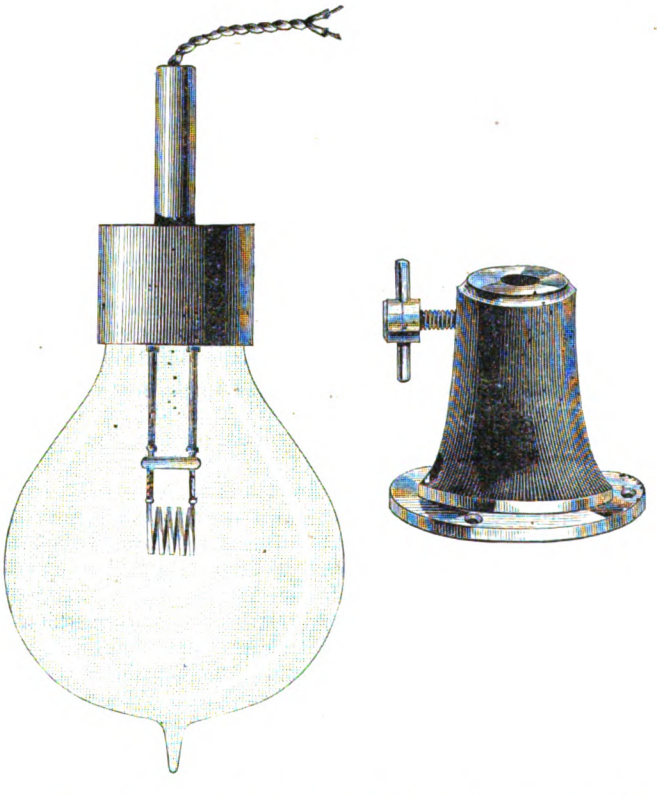
In a recent number of the *Zeitschrift für Elektrotechnick* Dr. Gerlach describes a cheap form of arc lamp made by M. Jordan, of Parchim, which he has been in the habit of using for several years for demonstration purposes. Into a wooden pedestal is screwed the metal socket a, holding the carbon k_1 and a metal support b, which is in electrical connection with one end of the coil c. The other end of the coil c is connected by a flexible wire, d, to the upper carbon k_2, through the iron holder e, which is capable of moving freely within the coil. When the current is passed through the lamp the iron-holder is sucked in and the arc is struck, and according as the current decreases and increases the upper carbon



is lowered and raised, the lamp thus proving self-regulating. If the current is strong enough to lift h, but is unable to maintain the arc, the small cylinders $f f$ can be attached to the carbon holder, which, by adding to its weight, diminishes the length of the arc.

AN INCANDESCENT LAMP FOR OPTICAL PURPOSES.

It is well known that if an ordinary incandescence lamp having a horse-shoe or looped filament is placed in the principal focus of a lens, the lens will gather into a parallel beam of light only a very



small portion of the whole light given out by the filament. In optical work a light is required which is emitted from a small luminous area capable of being almost wholly placed in the focus of a lens or reflector. Apart from their intrinsic brilliancy it is this compactness which renders the arc light and the limelight so effective as sources of light in optical apparatus. To meet this desideratum the Edison-Swan Electric Light Company have recently brought

Digitized by Google

out an incandescence lamp of a particular pattern in which a suggestion by Dr. Fleming has been practically worked out by Mr. Gimingham with the result of producing a glow lamp admirably adapted for these purposes.

The sketch shows the arrangement. In a nearly spherical bulb is fixed a carbon filament coiled into a flat spiral, the whole width and length of which is contained in an area of about one square centimetre. When the lamp is incandescent this flat spiral appears as an intensely luminous and compact focus of light, and when the lamp is placed in the focus of a lens and suitable mirror, nearly the whole of the emitted light can be condensed into an approximately parallel beam. A lamp of this kind, of 60-70 candle-power, is very well adapted for use in the optical lantern. We are informed that Dr. Fleming has had them in use now for a sufficient time in lantern work at University College to be satisfied with their performance. They can also be used with advantage in ship's side-light lanterns, and in small projectors. As the distribution of electric current extends in private houses it will be doubtless found that a simple form of optical lantern employing such an incandescent lamp is the most convenient and pleasing mode of exhibiting photographic slides and transparencies.

For lecture-room work, where current is available, it will afford a means of showing lantern views with less trouble than limelight or mineral oil lamps, and for use as a source of light which is, in some respects, more tractable than the limelight even though less intense, this form of glow lamp will have its uses. A suitable holder and stand has been designed for the lamp, which has been called the Ediswan Focus Lamp.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 6, 1889.

In one of my recent letters I called attention to some interesting figures showing how largely the gas companies in this country were now devoting their attention to the introduction of the electric light. It is a little bit amusing and singular to see that the old competition and hostility which is thus disappearing above ground should be renewed underground, and should be occupying very largely the attention of gas and electrical engineers. In other words, now that we are having electrical subways laid in most of our large cities the most important question that has arisen in connection with them is how to keep them free from gas. So far, no means have been found to prevent gas escaping from the pipes, and hence every now and then we have some bad explosions. There have been explosions in Philadelphia and other cities of serious proportions, and latterly New York has been startled by similar unpleasant experiences. Last week I mentioned the explosions near the Fifth Avenue Hotel up town,* which made a very deep impression on the public mind, and have now led to a special investigation of the matter by the Board of Electrical Control. The Board has had before it this week a number of representative men connected with the gas companies and the steam-heating companies, and has endeavoured to ascertain from them whether it would not be possible to prevent the leakage from gas-pipes. As far as it has gone it has discovered that there is considerable difference of opinion on this subject. Some of the gas engineers admit a direct loss of 5 per cent. by leakage, and appear to take it for granted that that is normal and reasonable, while others went so far as to intimate that it was unavoidable and was practically allowed for in the scheme of creation. Mr. Jackson, of the Westinghouse Company, a gentleman who has had great experience in connection with natural gas engineering in Pittsburg, said that in that city they had eliminated leakage from their calculations by careful work, and that the loss by that cause did not amount to one-half of 1 per cent. Admitting, however, that the gas-pipes in New York would leak, and that the gas escaping would find its way into the conduits, the Board had further to ascertain whether there was not some remedy for the explosions, and upon this second point a number of opinions were ventured. President Andrews, of the New York Steam-heating Company and of the Standard Gas Company, suggested that the ventilation of the manholes was the proper means, the covers being perforated; but Mr. Beckwith, the engineer of the Board, opposed this, saying that the gas escaping through the perforations of the covers would be more than ever likely to be ignited by stray matches. It was finally decided to make an experiment in ventilation by running small pipes through the manholes to the tops of the electric light poles, but there are doubts in some quarters as to the efficiency of this method. One of the technical papers here, the *Engineering and Mining Journal*, the editor of which is Mr. R. W. Raymond, who is one of the Subway Commissioners for Brooklyn, suggests that, in order to prevent the manhole lids from flying about in a loose and casual way, it would be a good precaution to fix them on one side with hinges, so that when the explosion did take place the cover would simply flap open like a door. It is obvious that this is a practical remedy, for the startled passer-by, as soon as he has recovered his equanimity after the explosion, can shut down the lid again, and a minute later nobody would be anything the wiser as to the occurrence of the explosion. The only trouble with regard to this remedy is that so far the explosions have not merely hoisted the covers in the air but the best part of the manhole too.

The rapid extension of electric railways in this country has, I notice, more than once called forth surprise and admiration in England, but I doubt whether the full scope of the revolution in urban passenger traffic is yet comprehended abroad. Figures and facts are always better than vague and general statements, and I am glad to be able to refer in this respect to some statistics which have recently been compiled by the *Street Railway Journal*. The results brought out exceed the most sanguine and most enthusiastic anticipations of electrical engineers. In a paragraph above I have alluded to the change of front with regard to electricity on the part of the gas companies, and I think that the street railway companies are even more appreciative of the benefits that the practical applications of the new force can confer on them. The *Street Railway Journal* reports having gathered the following data from several hundred replies to circulars which it distributed among the street railways of the country:—18 per cent. did not contemplate making any change from horses, and of this number one-fourth expressed themselves as satisfied with horses or unable to change because of the terms of their franchise; 15½ per cent. did not answer the questions at all; 16 per cent. were awaiting developments, desiring to change to mechanical traction whenever they could find a practical system, but preferring no particular method; 16½ per cent. favoured methods other than electricity, such as cable, gas motors and steam motors; 34 per cent. have either decided on electricity in some form or contemplate so doing, and of this number one-third prefer the overhead system and about one-ninth favour storage batteries. Thus out of the entire number of replies 66½ per cent. may be said to be so thoroughly dissatisfied with horses that they have already abandoned them or are watching for an opportunity of doing it; and if to that number we add the 15½ per cent. who did not answer the questions we might say that 75 per cent. of the street railways of the country have declared their sentiments against horses and in favour of mechanical traction. It will be noted that of the 66½ per cent. more than one-half favour electricity, and if we take into consideration the new roads being projected or built we shall find the proportion for electricity is even larger. It is evidently much easier to start out with electricity on a new road than to apply it to an old road already equipped with horses, stables and the old-fashioned rolling stock. I think it will be conceded by your readers that this is a remarkable exemplification of rapid electrical development.

As compared with England, this country has seen very little special building of dynamos for marine work. In the absence of a large mercantile marine and of an extensive navy, the opportunity has not presented itself to marine dynamo builders of much work in this direction; but latterly, with the greater activity in the establishment of what is known as the "New Navy," there have been some good chances, and the result is that one or two new and interesting special types of machines have been brought out. Just now it may be said that the Edison Company is practically monopolising the new naval

* This paragraph was held over last week for want of space; it will now be found in our Note columns.—ED. *E.*

Digitized by Google

work, and it has recently brought out for the cruiser "Yorktown" a new multipolar compound wound machine, with a Gramme ring armature, designed to give 100 amperes at 80 volts. This machine is a radical departure from the familiar Edison type, and the idea is, of course, to economise in space, material, &c. There are eight poles, four external to the armature and four internal, the latter being placed not opposite the external poles but in each case midway between them, so that any one section of the armature passes alternately over the internal pole and under the external. The field is generated by a circular coil in the shape of a field ring, which is inserted vertically between the two sets of poles occupying the space between the keeper and the armature, and also between the two sets of poles over the internal and inside the exterior. This field magnet consists of both series and shunt windings, and is kept in position by small projecting lugs on the pole pieces. The ends of each section of wire on the armature are soldered into the adjacent cups of the commutator bar, and after this connection is completed each cup is connected by a wire with the three cups at right angles to it and to each other. By this means only one set of brushes is required. The commutator has 144 bars, and the brushes are set at points on the circumference of the commutator, making an angle of about 135 degrees with each other. The switchboard is placed on the top of the dynamo. The machine is coupled direct with a special Armington and Sims engine. The connecting coupling between dynamo and engine-shaft is a flexible one, the connecting medium being a disc of leather. The weight of the dynamo, including the bed-plate, is about 2,000lb., giving 4 watts to the pound, and the larger machines of 200 amperes now being built for new cruisers give 5 watts to the pound. Allowing the normal heating area, as employed on the special machines built in Europe for this purpose, they give 12 watts per pound. The machines are provided with the new Edison pattern of self-oiling bearings, which have a reservoir of oil in the surrounding shell and require no oil cups. It may be mentioned that the specifications made by Lieut.-Commander Bradford required a temperature of the dynamo, after a test of one week's continuous run, not exceeding 40° Fahrenheit above the surrounding atmosphere on either the armature or the field magnet, with the additional condition that the maximum speed should not exceed 400 revolutions per minute.

The annual report issued last week by the American Bell Telephone Company shows that company to be in a highly prosperous state. The earnings will allow it to pay dividends on its total capital stock of 24 per cent., but the stockholders have to be satisfied with an insignificant 18, the sum of $600,000 being transferred from the net surplus of the year to a reserve account, the directors believing, with wisdom perhaps, that a part of the income from royalties should be treated as capital. It is interesting to note that the payment to the Western Union Company under the old contract for sitting still and doing nothing amounts during the past year to $467,000. It is probably as handsome a premium as was ever paid for indulgence in *dolce far niente*. The far-sighted policy which animates the management of the American Bell Telephone Company is seen not only in the transfer of the $600,000 to the reserve fund, but in its provision for a magnificent new telephone building in Boston, and in the fact that the investment in long-distance telephone lines now amounts to about £450,000, the greater part of this money having been obtained by the issue of 7 per cent. debenture bonds of the company for $2,000,000, which were offered to the stockholders at par and subscribed for by them. The business of the long-distance lines has been good, and is increasing, the service rendered being excellent; in fact, I think it may be characterised altogether as the best electrical service now being given in America. The business would be much better but for the fact that the larger cities still wait for the establishment of a metallic circuit system for their local lines. The company now has in the hands of licensees under rental no fewer than 411,511 instruments, being an increase for the year of 31,234. The subscribers in the various exchanges through the country make an average of 6·13 calls per day, and of these subscribers there are 171,000 concentrated in 742 exchanges and 452 branch offices, on 170,000 miles of wire, and served by 6,310 employés.

BERLIN NOTES.

(FROM OUR CORRESPONDENT.)

BERLIN, *April* 8, 1889.

On April 6 the ordinary general meeting of the well-known electric light company of Berlin, the Allgemeine Elektricitäts-Gesellschaft, was held. I therefore take the present opportunity to call attention to the development of this company and to give you a short account of the progress in electric transmission of power from the Berlin central stations. The chief resolution come to at the meeting was that the capital of 12,000,000 marks should be increased to 16,000,000 marks. The directors of the company justified their demand for an increase of capital by the extensions of the foreign business of the company, and especially in connection with several central stations. Indeed, the increase of capital is fully justified by the growth of the manufacturing business of the company, which during the past year was more than doubled. Moreover, no trifling portion of the capital has been expended in acquiring the German licenses of all the patents of the Electrical Power Storage Company and in establishing the manufacture of this branch of electrical engineering.

The manufacture of electric motors in Germany already forms a considerable part of the electrical engineering industry. Almost all electricians of any importance have designed new types of electric motors, the sizes of which vary from $\frac{1}{12}$ horse-power for sewing machines and other machines requiring little power up to 10 horse-power. All German engineers agree in the opinion that high efficiency should be the main point in designing electric motors, even if the number of revolutions or the prime cost come out very high. Though in Berlin the electric motor is not as yet generally used, nevertheless there are already a great many industrial power users to be found who avail themselves of electricity. Up to the present the motors have been most prudently employed to drive fans and ventilating apparatus; now, however, a great many shopkeepers and tradesmen have begun to recognise the advantages of the motors. Among the industrial consumers there are also shopkeepers who drive their sewing and cutting machines and their coffee and pepper mills by electricity, as well as printing offices and owners of pumps and lifts. For instance, in the lithographic printing office of Herr Winkelmann there are five electric motors, two 1 horse-power and three of $\frac{1}{2}$ horse-power. Each lithographic press has its separate motor of $\frac{1}{2}$ horse-power, and each machine for polishing the lithographic stones and plates has its motor of 1 horse-power, while the fifth motor of 1 horse-power drives three printing presses of various types and sizes through shafting. Notwithstanding the comparatively high cost of electric current in Berlin the working expenses do not greatly exceed those of gas engines. The electric motors of the Allgemeine Electricitäts-Gesellschaft are self-regulating, and have a very high efficiency; on account of the so-called ring lubrication of their bearings they need no oil supply more than once a month. In some cases the saving made by using electricity in lieu of other power may be very considerable; for instance, Herr V. Maulheimer, who has in his well-known establishment a lift which was driven till lately by hydraulic power, water being obtained from the town mains, has now established a pump driven by an electric motor, which pumps the waste water into a reservoir at a height of 25 metres. Since this alteration the working expenses of the lift are reduced by more than 25 per cent.

CORRESPONDENCE.

PROF. OSTWALD'S EXPERIMENT IN ELECTROLYTIC DISSOCIATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish to emphasise the criticism of Mr. J. Brown (p. 676) concerning what Prof. Ostwald has published regarding dissociation and electrolysis, and I regret to say it seems to be necessary to take rather serious ground. I trust that this seeming is owing to some misapprehension of mine, but I have delayed writing on the matter for six months or more in the hope of having it removed.

There has for long been some uncertainty and debate as to how the free, or potentially free, atoms, postulated by Clausius to explain electrolysis, were to be conceived; whether free charged atoms could really dance through the liquid, remaining dissociated for some time, or whether the postulate involved merely a slight modification of Grotthus' original hypothesis and signified only a directed molecular interchange of a very easy and unresisting kind.

I understand Prof. Ostwald to have espoused the former view, and to adduce in its support an experiment of a remarkable

Digitized by Google

character, the description of which is translated by Prof. Ramsay in *The Electrician* of March 1 as follows:—"Two glass vessels, insulated, each contain a solution of potassium chloride. They are connected together by a siphon filled with a similar solution of potassium chloride. A negatively electrified rod is placed near one of the vessels, and while it is still there the siphon is removed. The vessel nearest the rod is now positively electrified; it has received a positive charge from its neighbour vessel, and this charge has carried with it positively electrified potassium atoms, while negatively electrified chlorine atoms remain in the other vessel. These atoms are *free* in the solution. When a conducting wire is now dipped into the solution, the potassium atoms float up to it, part with their positive charges, and then act on the water, forming potash and evolving hydrogen, which, if the charge was great enough, appears in bubbles, but which at all events polarises the platinum wire. Such an experiment shows that it is easy to prepare a liquid containing excess of one or other ion, and to separate the ion at the surface of an electrode by removing the electric charge of the ion."

I have seen the original Paper, and the above appears to me a fair representation of what it says.

Now among the mass of publication and scientific literature in which we are imbedded, if there is one thing more than another directly incumbent upon persons in authority, as a matter of simple morality, it is this: that all experiments recorded by them should be as absolutely trustworthy as they can be made, so that a person reading the description may be able to rely on the statements of fact as accurate, however he may please to differ from the views and interpretations put upon those facts.

Concerning this experiment, however, I was incredulous in spite of myself, and in spite of the high position of its author. Nevertheless, as in duty bound before saying anything about it in public, I proceeded to try it, although at every step the absurdity of the proceeding forced itself upon me. I connected two insulated vessels of KCl by a siphon; I brought near one a stick of rubbed ebonite, then removed the siphon, and immersed a platinum wire in each of the solutions. I have now to record that I saw no "potassium atoms floating up to the wire and parting with their positive charges," that I could detect no "formation of potash," see no "bubbles of hydrogen," nor could I be sure of the least trace of polarisation.

Now if it is merely my bad experimenting which accounts for these negative results, I shall be very ready to apologise. But in the light of my trial, and of such experience of electrical and chemical matters as I have been able to accumulate, I feel bound to say deliberately that I do not believe the experiment as described is a feasible one, and I do not believe the results described were ever witnessed.—Yours, &c.,

Grasmere, 10th April, 1889. OLIVER J. LODGE.

THE BERLIN CABLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think it would be interesting and important to know the section and approximate daily current curve of the Berlin cables, as it might turn out that at the time of full load they are heavily worked, and that in consequence there is considerable rise of temperature, which would accelerate deteriorating actions. Perhaps Prof. Forbes could furnish us with the necessary information to make this calculation?

One is reminded of the rapid deterioration of lead wire fuses, but this may be caused by the alternate heating and cooling cracking and detaching the superficial film of oxide which would otherwise protect the bulk of metal. Perhaps this action, combined with increased chemical action due to elevation of temperature, may be to some extent the cause of the failure of the Berlin cables.

We have, however, the fact that composition pipes are largely employed for both gas and water, and are buried in the soil without much distinction as to nature of soil, so that it would appear that the cable manufacturers have only to ascertain the experience of gas and water companies in order to secure a cheap alloy which, under ordinary temperatures and temperature variations, has stood the test of experience. Probably hot water engineers have experience on the behaviour of "compo." piping under very similar conditions to those which would obtain with a heavily worked cable.—Yours, &c.,

Lisbon, April 7, 1889. W. B. SAYERS.

[Load diagrams of the Berlin stations were given in *The Electrician* of June 29, 1888, p. 244, but we have no information as to the current density in the cables.—ED. *E.*]

STORAGE BATTERY PATENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As a leaderette in your last issue on the recent decision in the United States Courts on the above subject may give rise to erroneous impressions, I would wish to point out that, far from the decision being unfavourable to the Accumulator Company of America, who hold the E. P. S. group of patents, it will enable them at once to place under injunction all who employ the only practical and commercially useful system for the manufacture of storage batteries, viz., the mechanical application of active material to the plates.

It is well known that no secondary battery has been successfully constructed in which the active material is not mechanically applied in the form of a paste, paint, or cement, and the attempt of Mr. Brush to make batteries otherwise resulted, as is a matter of common knowledge, disastrously to himself and his sub-companies in America, the whole of the batteries having to be taken back.

I would point out that we have not to deal with Mr. Brush in this country, and that though the judgment stated there was no doubt Faure made the invention in August, 1878, yet he was precluded by the American law (because he is a foreigner) from claiming the invention earlier than the date of his French patent, which was October, 1880; whereas the evidence of Brush was directed to the years 1879 and 1880 as the years in which he made his so-called discoveries.

As regards the Swan patent, the judgment decides that the invention of Swan is a patentable invention, and it quotes the evidence of Sir William Thomson thereon; but it holds the Swan patent in America to be invalid, because a Prof. Eaton testified that he made something similar to Swan's invention in August, 1881, whereas Swan's patent for the United States only dated from January, 1882, and the plaintiffs had not put in proof the date of the English patent, which was May 24th, 1881.—Yours, &c.,

J. IRVING COURTENAY, Managing Director of the Electrical Power Storage Company (Limited).

London, April 17, 1889.

DURTNALL v. SHIPPEY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Our attention has been called to your report in last issue respecting the above matter, which, permit us to say, has no connection with our firm whatever; and from inquiries we have made, your correspondent appears to have misrepresented the case altogether, which has nothing to do with us. We must therefore request you to insert this letter in your next issue, as we cannot allow such an erroneous report to go uncontradicted.—Yours, &c., JOHN TADD, Secretary.

(Shippey Brothers, Limited.)

COMPANIES' MEETINGS & REPORTS.

The Oriental Telephone Company (Limited).

The ninth ordinary annual general meeting of this Company was held on the 16th inst. at the City Terminus Hotel, under the presidency of Mr. William Addison.

The SECRETARY (Mr. Alex. B. Chalmers) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, In moving the adoption of the report and balance-sheet I congratulate the shareholders upon the steady although comparatively slow improvement in the position of the Company. Each year we are doing better, although the progress is certainly not rapid. With regard to the balance-sheet, your Directors, after having well considered the matter, have thought it better to recommend the distribution of a smaller dividend than apparently on looking at the balance-sheet they might have done, and their reasons for such policy are—First: To protect the shareholders from the possibility of a call by forming a reserve fund sufficiently large to meet any emergency that the Company may have to face, such as destruction of poles, wires, etc., by storms or cyclones. This reserve fund your Directors intend to make a thoroughly real one and to invest it in such substantial securities as may be easily realisable should the money be required quickly. Secondly: To enable your Directors to have sufficient money in hand for the purpose of pushing and extending the business should opportunities occur of advantageously doing so without having to call on the shareholders for more money; this we consider most important. Thirdly: Your Directors have a great objection to see brought forward in the balance-sheet from year to year a large sum for preliminary expenses, so after careful thought they have resolved to wipe that item off the accounts. These are the main reasons your Directors have in recommending a 3 per cent. dividend when perhaps another ½ or 1 per cent. might have been paid. But there is still another reason, which is this—having in view the future prosperity and stability of the Company, they are anxious to maintain steady dividends. Now you are all aware that 75,000 fully paid £1 vendors' shares will rank for dividend as soon as 30 per cent. in dividends has been paid to the other shareholders, having 11s. paid on their £1 shares, and which constitute by far the larger proportion of shareholders, viz., 3 to 1 of the capital. Having that in view, we think it just to these shareholders that we should use the power our Articles of Association give us to raise such a reserve as we may consider necessary whether for the protection of the Company or for the equalisation of dividends. The Board have control over rather more than one-third of the whole vendors' shares, 26,000 out of 75,000, which should satisfy the meeting that the interests of all classes of shares have been considered. In India the progress of the subsidiary companies is slow, and it is certainly not helped by the policy of the Indian Telegraph Department, which seems to your Directors almost antagonistic. Until some amelioration in the relations of the Indian Companies and the Indian Telegraph Department has been effected, we shall continue to advise the utmost economy compatible with efficiency in the administration of their affairs. Our property in Egypt is certainly of no less value than it was twelve months ago. As you will see by the report, the Directors of the Telephone Company of Egypt have placed £5,000 of debentures in Egypt at 6 per cent. interest. This we consider a fair rate taking into account the high rates of interest which are obtained in the East. As I have told you on several occasions, your Directors have always considered it mutually advantageous to both classes of shareholders to have only one class of shares, and they invited by circular the vendors' shareholders to meet the Board. As negotiations are in progress it is impossible for me to enter into details now. I am glad to say that at no exchange of the Company has there been a falling off in the revenue during the past year, and in several a very fair increase. I will detain you no longer, but will formally move the adoption of the balance-sheet and report now presented, and if any gentleman has any questions to ask I shall be happy to answer them.

The Right Hon. G. A. F. CAVENDISH BENTINCK seconded the motion.

Mr. POWERS thought it an extraordinary proceeding that such a large sum as had been mentioned should be taken out of the money earned by the Company and added to reserve fund, seeing that there was a reserve fund of 9s. a share uncalled on 220,000 shares. If a call were made for the development of the business he had no doubt that it would be readily responded to. It would in his own case, though he held over 1,000 shares, the majority of which had cost him 15s. each. He therefore considered it entirely unnecessary to form a reserve fund in the manner suggested by the Directors, by keeping so much of the earnings of the Company out of the shareholders' pockets. They had been waiting very patiently

Digitized by Google

and now that the money could be paid to them they ought to receive it. He did not believe that the telephone business could be increased in Egypt and in the East, for they had already been at work between eight and nine years. He did not believe that a case had ever before been heard of a company which had earned £6,000 in a year and had never had a reserve fund, and then suddenly for such a fund to be created by keeping from the shareholders one-half of the amount they ought to receive. They had earned 5 per cent. and were to receive 3 per cent. Was such a proposal as that made because certain shareholders did not wish the 30 per cent. mentioned by the chairman to be reached, so that the vendors' shares should not come in for dividend? The vendors did nothing for the business. He repeated that the shareholders ought to receive now what the Company had earned. He did not consider that a reserve fund was required at all in such a business, and he thought the money was being kept back to provide for something that was going to come up that would settle the differences between a £1 share and an 11s. share.

The CHAIRMAN, in reply, said: I am sure that a call on the shares would be strongly opposed by every holder of the ordinary shares. When the present Board took office it was on the understanding almost that we would not make a call—certainly that we would try and carry on the business without making a call. The security of the uncalled capital of 9s. a share is a very heavy liability, and I cannot imagine that any holder of the ordinary shares should wish to be under the liability of that call being made. Mr. Powers said that there is no possibility of an extension of our business. Well, we have under consideration one or two plans in connection with which we may open up fresh places. The preliminary expenses of £3,000 have been written off this time. You see that £3,500 or £3,600 was brought into the account and £600 or £700 carried forward, so it is really more a question of account than anything else. Mr. Powesr remarked that the Egyptian Company had paid us £5,000 this year. That is very true, but it did not accrue in this year. It was a debt which had been owing since the formation of the company. Upon their placing those debentures that company paid us off this £5,000, which gives us the money in hand out of which we are now able to propose this dividend to you.

Mr. POWERS observed that his point was that no reserve fund was required, and there ought to be a substantial reason given for creating one.

The CHAIRMAN: I mentioned in my opening speech that the reason for a reserve fund in a great measure was to enable the Directors to push and extend the business should opportunities occur. We have now in view one or two probable extensions, and we have no money towards opening an exchange unless we form a reserve fund. The only other alternative would be a call, and I am sure from my experience that the great body of the shareholders—99 out of 100—would be strongly against a call. That was their feeling when we took office, and we have strained every effort to act up to that feeling.

The resolution was then put and declared carried by 18 to 17.

The CHAIRMAN then moved the following resolution:—

"That a dividend at the rate of 3 per cent., free of income-tax, for the year ended December 31, 1888, be declared on the paid-up capital of the Company other than the vendors' shares."

Mr. B. ST. JOHN ACKERS seconded the resolution, and it was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. FROST, Mr. Grëwing was re-elected a Director, Mr. Frost referring to that gentleman's large holding in the Company, and Mr. Thomas Lloyd was also re-elected to his seat at the Board.

On the motion of Mr. LEAN, seconded by Mr. FITZGERALD, the auditors, Messrs. Deloitte, Dever, Griffiths and Co., were re-elected.

The Rev. Mr. DAY then proposed a vote of thanks to the Chairman and Directors. The shareholders, he observed, might not all agree with the Directors in the policy of building up a large reserve fund; but it was, at all events, a safe policy. They all owed a great deal to the Directors who were steering the Company through its difficulties; and he, for one, was perfectly satisfied with their action.

Mr. SEAMAN seconded the motion, which was unanimously adopted.

The CHAIRMAN having replied, the meeting separated.

Reuter's Telegram Company (Limited).

Admiral the Right Hon. Sir J. C. D. Hay, Bart., K.C.B., presided over the twenty-fifth ordinary general meeting of the shareholders in this Company, held on the 17th inst. at the offices, Old Jewry.

The SECRETARY (Mr. F. J. Griffiths) having read the notice convening the meeting,

The CHAIRMAN said: In moving the adoption of the report and balance-sheet I must first express the great regret that Colonel Holland, who so long filled this chair, is no longer here to superintend the business of the Company. He has reached an age at which he is entitled to seek repose. He has been identified with the Company for twenty-five years. He felt that he was no longer sufficiently active to ensure regular attendance, and he was too conscientious to hold a post of which he feared he might not be able fully to discharge the duties. Our Managing Director is engaged in important negotiations with our Continental allies, and it would be indiscreet at present to analyse the figures of our accounts for the past year. They are of an abnormal character. Though the net result is not so favourable as could be wished, it is nevertheless not discouraging, as the Company had suddenly to face a loss of revenue, and could not at once take countervailing measures of economy at the agencies affected. The falling off in the profits belongs chiefly to the first months of 1888. We have also had special arrangements for news of an exceptional character in distant parts of the world; for instance, on the East Coast of Africa and in Samoa, countries from which a service of telegrams is very costly. We had further and alone most expensive telegrams detailing the progress of Mr. Stanley's expedition for the relief of Emin Pasha. Without boasting, it may satisfy the shareholders to know, as examples of our success, two instances which are very striking. In December last we announced the safety of Mr. Stanley in advance of all other sources of information, and our telegram was communicated to the House of Commons. Last Saturday week we announced with deep regret the calamity which had befallen the squadrons of Germany and the United States at Samoa, before any of the Governments concerned had knowledge of the disaster. In conclusion, we trust that the shareholders will continue to us the confidence we have enjoyed for so many years, and will accept our assurance that the negotiations now in progress will strengthen our position, by renewing and cementing our foreign alliances, upon which depend in great measure our immunity from what may be called fratricidal competition.

The motion was seconded by Baron de REUTER.

Mr. MAURICE GRANT stated that he was sorry to sound any discordant note at the meeting, but he happened to be one of the eight largest shareholders, and therefore he took a great interest in the Company apart altogether from sentimental notions. The world at large was indebted to Baron de Reuter for his efforts in the past in the direction of disseminating reliable information from all quarters with the strictest impartiality. It seemed to him that the question between the shareholders and the Directors was a very simple one. The figures he had analysed were very remarkable. The Company appeared to be a philanthropic society for the dissemination of news for the benefit of the public, and for the paying of salaries to various *employés* throughout the world. The result to the shareholders seemed to be the very last matter that was present to the minds of the Directors, though he said that with all respect. They appeared to have done business last year to the extent of £86,000 and in the pre-

vious year to the amount of £91,000, and the net profit in the previous year was only £4,000 odd, while in the past year it had been only £1,200. They had carried on the whole business with the greatest possible skill and success, and all that the shareholders had got, after taking the commercial risks of the undertaking, was to receive £1,200 distributed among them. The current expenses, including salaries, &c., had been £20,000 ; in other words, it had taken 25 per cent. of all their receipts to pay for administration expenses. Either they were charging too little to the newspapers to whom they supplied information, or they were paying the *employés* unfairly. He knew that they had to meet competition, but their Company was at the top of the tree. They were only getting 1½ per cent., for the way the dividend was made up to 5 per cent. was by eating up the reserve fund. The pruning knife must be applied to the salaries, or their charges to newspapers must be increased ; the shareholders must live.

The CHAIRMAN : As the speech of the hon. gentleman has not been followed by a motion I think I need add very little to what I have said. But there is one point that is so creditable to our *employés* that it should be known, namely, that during the course of this year all the *employés* receiving over a certain amount, all excepting those having only very low salaries, have agreed to suspend 10 per cent. of their remuneration ; and the directors have only taken half the amount to which they are entitled. We had no desire to place that prominently before you. The payment is merely suspended because we trust that the time may not be far distant when the *employés* may receive what is their due. Mr. Grant, after his remarks, will be glad to hear that that point has not been neglected by the Directors, and that the various *employés*, with the most loyal feeling, at once accepted the arrangement.—The Chairman then put the resolution, and it was carried unanimously.

Baron de REUTER : I beg to propose the re-election of our retiring Director, Admiral the Right Hon. Sir J. C. D. Hay, who has been connected with our Company since its creation, and who is favourably known to every one.

The Hon. MARK F. NAPIER seconded the motion, which was carried unanimously.

The CHAIRMAN : I beg to thank you for re-electing me. The Directors have placed me, however unworthy, in the position lately occupied by our friend Col. Holland, and I shall do my very best to assist the Board in perfecting the arrangements which are now under consideration. I trust that at our next annual meeting we shall be able to present a much more successful report and balance-sheet.

On the motion of Mr. LOVEDAY, the auditors, Messrs. Welton, Jones, and Co., were next re-elected.

Mr. GRANT then proposed a vote of thanks to the Chairman and Directors, and the motion having been seconded, it was unanimously agreed to.

The CHAIRMAN : I am very much obliged to Mr. Grant and the shareholders for the confidence they have expressed in the Directors and the Chairman, who has already addressed them in acknowledging his re-election. I can only express my gratitude for the confidence which the shareholders have shown, and on behalf of my colleagues and myself. I can promise them that we will, as hitherto, do the best we can to promote the welfare of the Company.

The proceedings then terminated.

The Indo-European Telegraph Company (Limited).

The following is the report of the Directors of this Company for 1888, which will be presented to the twenty-second ordinary general meeting of the members, to be held at Winchester House, 50, Old Broad-street, London, E.C., on Monday, April 29, at 12 o'clock :—

The Board of Directors have to express their deep regret at the retirement from the chair, after an occupancy of seventeen years, of Colonel James Holland, and to express their satisfaction at the acceptance of that office by the present Chairman, Mr. J. Herbert Tritton.

The Company's revenue from all sources for 1888 amounted to £110,327. 7s. 7d., as compared with £104,290. 18s. 3d. for 1887, showing an increase of £6,036. 9s. 4d.

The expenses were on commercial and general account, £28,609. 12s. 9d.; on maintenance account £23,783. 11s. 10d., including £84. 17s. 8d. paid to the Russian Government ; total £52,393. 4s. 7d., as against £48,620. 15s. 3d., an increase of £3,772. 9s. 4d. Deducting the above expenses, taking credit for £2,694. 15s. 1d. brought over from 1887, and debiting income tax, there remains the sum of £59,283. 18s. 7d. From this amount £10,000 has been placed to reserve, and that sum, together with £10,625, amount of interim dividend, have to be deducted, leaving a balance of £38,658. 18s. 7d.

The Directors now propose the declaration of a dividend for the last six months of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income tax, making in all 10 per cent. for the year, carrying forward £6,783. 18s. 7d. to the credit of 1889.

It will be observed that the balance carried over is larger than usual. Provision has to be made, however, for extensive alterations and additions to the system which must be effected during the current year, and the recent interruption of both the Company's cables in the Straits of Kertch has also entailed exceptional outlay, so that the whole of the additional amount carried over will be absorbed. The falling off in the revenues derived from Indian messages upon the reduction of tariff, remarked upon in 1886 and 1887, continued during 1888, but fortunately has again been made up by other traffic.

The following Directors retire by rotation and offer themselves for re-election :—C. W. Earle, Esq., and J. Berenberg Gossler, Esq. The Auditors, Messrs. C. F. Kemp, Ford and Co., Public Accountants, retire and offer themselves for re-election.

The transfer books will be closed from the 15th to the 29th instant, both inclusive.

NEW COMPANIES REGISTERED.

BRITISH TANNING COMPANY.—This company has been formed with a capital of £70,000 in £1 shares, to purchase from Messrs. Worms and Balé, of Paris, their patent for the United Kingdom for an improved system of tanning by the aid of electricity, to work the patent process, and to grant licenses to tanners in Great Britain and Ireland. The process is stated to have been for the last six months in full work in France, and to cause a reduction in the cost and time occupied in tanning. It has been tested by experts whose reports accompany the prospectus. The intention is first to establish a tannery in London with twenty sets of apparatus, each capable of turning out about 140,000lb. of leather per annum, or 2,800,000lb. in all.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 5, 1889, amounted to £3,407.

DIRECT UNITED STATES CABLE COMPANY.—The Board of this company has resolved upon the payment of an interim dividend of 3s. 6d. per share, free of income tax, being at the rate of 3½ per cent. per annum, for the quarter ending March 31, 1889, such dividend to be payable on and after the 26th inst.

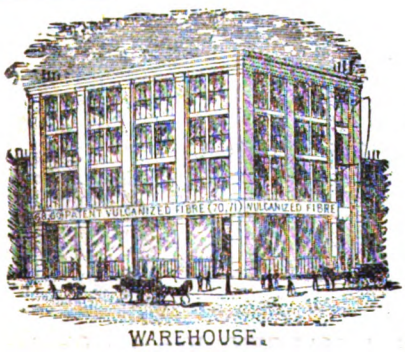
THE ELECTRIC DATE AND TIME STAMP COMPANY.—We are requested to state that there is no connection between this company, which was recently floated for the purpose of acquiring the patents of Mr. C. A. Randall's ingenious invention, and the "Time Stamp Company," against whom a winding-up order was granted by Mr. Justice North on Saturday last.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 5, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £2,171.

PERSONAL.—We are requested by Mr. Slater Lewis to state that he has resigned the managing directorship of the Telegraph Manufacturing Company, and that all correspondence intended for him should be addressed to his private house at Helsby, near Warrington.

——— Mr. G. J. Reed has retired from partnership with Messrs. W. H. Dingle and E. Stilliard, Victoria-street, Westminster, electricians.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

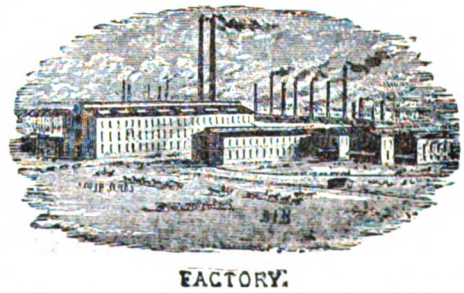
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 571.—Vol. XXII. FRIDAY, APRIL 26, 1889. Price Fourpence.

NOTES.

It remains to be seen whether the action of the Postmaster-General in declining to sanction the proposed transfer of the licenses of the three leading Telephone Companies will or will not have any effect in preventing or even in retarding the amalgamation scheme. Seeing, however, that the license already in possession of the United Company virtually covers the whole of the country, it is difficult to see in what way Mr. Raikes' refusal can have any important bearing upon the issue. At the same time it unmistakably proves that he is not at all anxious to do anything to facilitate the transaction. But if the Postmaster-General means to hinder as far as he can the establishment of inter-urban telephony by the Telephone Companies, we trust that the Department over which he presides is prepared to undertake the work on its own account. That long distance telephony is bound sooner or later to be extended throughout the country is a proposition which we believe to be indisputable, and the public will see to it that the Post Office either does the work itself or stands aside (with its 10 per cent. royalty) whilst others undertake it who are able and willing to do so.

The evidence on behalf of the promoters of the Electric Lighting Provisional Orders was concluded before the adjournment for the Easter holidays, and the cases of the various local authorities concerned will now be taken as regards each company in order. The evidence reported in this issue is of considerable interest, particularly that relating to the lighting of the City.

An experiment described by M. J. Borgman (*Comptes Rendus*, April 8, p. 733) has an important bearing upon the explanation (which, however, is still wanting) of the remarkable discovery of M. Hallwachs, in which a beam of light seems to act as a conductor for an electric current. This latter experiment was described in *The Electrician* of February 8, 1889, p. 409, but in case any of our readers have forgotten it we may briefly remind them that a piece of metallic gauze (or a sheet of perforated metal) is placed parallel with but insulated from a second sheet of metal. The first is connected with the positive and the second with the negative pole of a battery, and in one of the leads a delicate galvanometer is placed. If now a beam of light be caused to pass through the gauze and to fall on the plate behind, a current is set up in the circuit and continues to flow as long as the illumination is maintained. It has moreover been shown that the action is due to the ultra-violet waves. Now, M. Borgman wanted to ascertain whether or not the effect was instantaneous—that is to say, whether the commencement and the cessation of the current was or was not simultaneous with that of the illumination. M. Borgman probably reasoned—though this he does not say—that if the beam acted in some sense as a conductor of the current the effect must be instantaneous, while if the phenomenon resulted from some secondary action it would probably go on increasing up to a certain point with the duration of the illumination, and it would also probably continue for a short time after the light had been cut off. His method of making the test was equally simple and ingenious. The light was interrupted at rapid intervals by means of a rotating disc with holes or slits, and he placed a telephone in circuit with the battery. It is, then, obvious that if the effect is instantaneous the telephone will produce a note corresponding in pitch to the velocity of the disc—if otherwise there will be silence. There was silence. A make-and-break in any other part of the circuit could be heard, but not in the ray of light. Hence we must seek for some secondary action on the surface of the plates to explain M. Hallwach's experiment.

At the last meeting of the Berlin Electrical Society, Dr. Werner von Siemens read a Paper on lead-covered cables, intended as a rejoinder to the recent remarks of Prof. Forbes. Dr. Siemens gave the explanation which has already been given at the Institute of Electrical Engineers as to the circumstances under which Prof. Forbes had been led to take a view which was no doubt unduly unfavourable. The following passage from Dr. Siemens' Paper is of interest:—

"That there is no reason to assume a general and considerable deterioration of insulation is proved by the measurements of cables of similar construction which have been laid by Messrs. Siemens and Halske in other localities. Ten cables of similar construction, of about 1,688 m. length, were laid in Munich in 1884 for lighting the theatre, and were tested on the 9th March of this year; nine of these cables showed an average insulation of 50 millions of ohms per kilometre, whilst one cable showed an inferior insulation, which, however, has not affected the working yet. Immediately after being laid, these cables had an average insulation of 160 millions of ohms per kilometre. This diminution of insulation, which is practically of no account whatever, is only apparent, since the cable terminals are situated in unheated damp rooms, and could not be carefully dried and insulated, as would be required for measurements of such high insulations."

Our New York correspondent describes a device due to Prof. Elihu Thomson, by means of which a constant (mean) alternating current may be maintained in the secondary circuit of a transformer supplied with constant potential in the primary. The arrangement is an interesting one, but it does not seem to be very different in principle from the employment of "choking coils" in the primary and secondary circuits. If suitably adjusted this would at any rate have the same effect. The object aimed at is apparently to facilitate the use of arc lamps on transformer circuits. For our own part we think that the proper way of dealing with this problem is to adapt the mechanism of the lamp itself to the particular conditions under which it has to work. This has already been done with perfect success by at least one English firm, and we should strongly recommend all makers of direct-current arc lamps to turn their attention to this matter, if they have not already done so, without loss of time.

In the laboratory of the Sorbonne, MM. Pellat and Potier have made a new determination of the electro-chemical equivalent of silver by means of the absolute electro-dynamometer constructed two years ago by M. Pellat and presented by him to the Société de Physique. Two experiments, conducted with all known precautions, gave 1·1189 and 1·1195 respectively as the number of milligrammes of silver deposited by one ampere in one second. The mean of these figures is 1·1192. The previous determinations are :—

Kohlrausch	1·1183,	Mascart	1·1156,
Rayleigh	1·118,	Pellat & Potier	1·1192.

It is perhaps worth noting that if Mascart be allowed a weight in accordance with its wider divergence, then Rayleigh's value is almost exactly the mean of the four. It is, therefore, permissible to look upon this latest determination as a confirmation of the result previously accepted in this country.

We have received the following communication from a correspondent :—"The Electro-lunatic presents his compliments to the Editor, and begs to inquire, through the columns of *The Electrician*, whether the eminent firm of electrical engineers who are tendering to light the town of Cork with 16-candle lamps, using only 25 watts per lamp, are prepared to supply the public in general with a similar article; and, if so, whether they will guarantee that the lamps running under these conditions will last as long as a thousand seconds?"

When the Paris Municipal Council proceeded, a few days ago, to the election of five technical members of the Commission de l'Usine Municipale d'Electricité, it was found that M. Hospitalier, the well-known editor of *L'Electricien*, was amongst those elected. Upon this, M. Faillet, a member of the Council, remarked that it was a great pity *(il est fâcheux)* that a gentleman who was understood to have recommended the employment of English machines should be on the Commission. M. Faillet proceeded to remark that he regretted that they had not preferred some one who would have appreciated and would have made known the superiority of the French machines, "a superiority recognised by the whole technical world." M. Hospitalier wrote to M. Faillet politely inquiring what he meant by this, and asserting that his opinions of the merits of electrical machines were founded upon scientific grounds, and not on the question of nationality. Now, we do not know whether or not M. Hospitalier would agree with us—M. Faillet certainly would not—but for our own part we consider the French manufacturers to be singularly behindhand in the design of dynamos and motors. German and American makers, to say nothing of the English, beat them easily. Up to the present time all the more important central station work that has been carried out in France has been done by foreigners, such as Ganz and Co., Thomson-Houston, Edison, Ferranti, and Crompton, whilst we have yet to learn that any central station work has been carried out abroad by French firms. In the country of M. Gramme this is not a little singular. We believe, however, that the reason is exemplified by M. Faillet, who believes that the French dynamos must be the best for no better reason than that they are French.

The April number of *Blackfriars, The Post Office Magazine*, contains a bright little sketch, by Mr. R. C. Day, of race meetings from a telegraphist's point of view. The cause of the demoralisation of the turf has been the subject of considerable discussion of late, and we are inclined to think that the real culprits have been completely overlooked. It is very evident from Mr. Day's little article that the turf, as at present instituted, could not exist without the telegraph, so that the Post Office and the Wheatstone Automatic must share the blame of this demoralisation between them. The delinquents, however, certainly suffer for their sins, for a more appalling picture than the sudden charge of the excited turfites on the Epsom Grand Stand office after the Derby it is impossible to imagine; and when we add that close upon 10,000 messages are despatched from this office alone in the course of the day, we think it will be generally agreed that the punishment is proportionate to the offence. Mr. Scudamore used to say that the inside of the Grand Stand office immediately after a great race is the best place to study "varieties of hands." That witty gentleman probably had in his mind the "legs" as well.

The Committee for the Suppression of Electrical Quackery sends us a copy of a pamphlet entitled "An Exposure of Electrical Quackery," containing a reprint of the correspondence and editorial remarks upon this distressing subject which have from time to time appeared in the columns of our contemporary the *Electrical Review*. The Preface states that the object of the pamphlet is "to enlighten the Press and the Public upon the nefarious practices of the vendors of bogus electrical appliances." This is a movement with which we are in the fullest sympathy, and we trust that the Committee will feel themselves strong enough to bring the Chief Impostor of the Fraternity before a Court of Law. As regards the behaviour of the daily press in this matter, it is difficult to find words strong enough in condemnation. We would suggest further that steps be taken to bring the matter to the notice of Parliament—we are not at all sure that quack medical advertisements might not be made the subject of legislation.

Digitized by Google

MEANWHILE we are also glad to learn that active steps are being taken with the same object in another direction. Those interested in the medical aspect of the case would do well to place themselves in communication with the Editor of *Brain*.

Sir John Pender.—Last week's issue of the *Municipal World* gives by way of supplement an excellent ink-photo portrait of Sir John Pender, K.C.M.G., illustrating one of that paper's series of "Sovereigns of Labour and Industry."

Modum.—Some English capitalists, says *l'Electricité*, have purchased a powerful waterfall near Modum (Norway) for £6,000. The power available amounts to about 4,000 horse-power, and it will be used for electrical installation purposes.

Plymouth.—Steps are being taken in this town by the House-to-House Company to form a local electric lighting company, and we understand that the Corporation are disposed to consider favourably the question of the lighting of the streets by electricity.

St. George's (Hanover-square) Vestry.—At a meeting of the Works Committee of this Vestry on Tuesday last week a letter from the solicitors of the Metropolitan Electric Supply Company was read, announcing the intention of that company to erect a central lighting station in Eccleston-square, Pimlico. It was decided to take no action in the matter.

Electric Lighting in the Inner Temple.—The elaborate preparations made some time since for the purpose of illuminating the chambers and offices in the Inner Temple with the electric light have now been definitely abandoned, and the extensive excavations made in the Inner Temple-gardens for the reception of plant and machinery are now being filled in.

Norwich.—The Corporation of Norwich have adopted the following resolution:—"That this Council endorse the application of Messrs. Laurence, Paris and Scott (Limited) to the Board of Trade for a Provisional Order similar to that adopted by the Ipswich Town Council, and that if the order is obtained this Council will further in any way that is lawful the carrying out of electric lighting in this city." During the discussion it was stated that the lease of the New Mills would expire shortly, and that the water-power there, which was equal to 30 horse-power, would be sufficient to light all the open spaces in the city.

Deaths by Lightning.—At the meeting of the Royal Meteorological Society, on the 17th inst., a Paper "On the Deaths caused by Lightning in England and Wales from 1852 to 1880, as Recorded in the Returns of the Registrar-General," was read by Inspector-General R. Lawson, LL.D. The total number of deaths from lightning during the 29 years amounted to 546, of which 442 were of males and 104 of females. In consequence apparently of their greater exposure the inhabitants of rural districts suffer more from lightning than those of towns. It appears also that vicinity to the west and south coasts reduces the chances of injury by lightning, and that distance from the coast and high land seems to increase them.

Electric Light at the Mysore Palace. — The Maharaja's palace at Mysore is, says the *Indian Engineer*, soon to be lighted throughout with electric lights. The first storey of the palace will contain 62 lamps and the second 120. They are all to be incandescent lamps of 16 candle-power. The palace will be also lit with 6 arc lamps of 2,000 candle-power each, while at the very top of the palace will be the largest projector lamp in India, of 5,000 candle-power, which is intended to throw a light from 60 to 80 miles distance, and cast a shadow which, if thrown up, will be seen at Madras, Ootacamund, etc. The lights will be run off 53 accumulators. The arrangement of lighting by electricity has been calculated to be a saving to the exchequer.

Philosophical Society of Glasgow.—At the last meeting of this society, which was held in the Natural Philosophy Class Room at the University, Sir William Thomson gave a most interesting series of experiments with the gyrostat in its various forms, and by means of them he was enabled to demonstrate many important principles of physical and mechanical science. (The learned professor gave the same demonstration on the night of the 19th inst. under the auspices of the Natural History and Philosophical Society of Belfast, his native town.) Mr. J. T. Bottomley, F.R.S., subsequently explained the methods followed in measuring the electric resistance of glass plates. He also exhibited two Leyden jars which had been broken by a powerful discharge of static electricity, and pointed out the curious properties of the fracture.

The Lighting of the City.—At the last meeting of the City Commission of Sewers, Colonel Harwood, the Engineer to the Commission, reported that under permissions given by them two experiments in public lighting were now being carried out in the City—the one by the Gas Light and Coke Company and the other by the Defries Safety Lamp and Oil Company. Both experiments were at the expense of the applicants, and were to last one entire year. The streets in which they were being conducted were Cheapside, Poultry, Mansion House-street, Threadneedle-street, Cornhill, Royal Exchange-avenue, King William-street, Princes-street, Queen Victoria-street, Newgate-street, where 112 new lamps of the Gas Light and Coke Company were being tried, and in Holborn-viaduct and Holborn-circus, where 30 petroleum oil lamps of the Defries Company were in operation.

The Electric Light in Johannesburg.—A correspondent writes us from Johannesburg as follows:—"The property of the Robinson Gold Mining Co. has recently been lit by electricity. The installation comprises a dynamo driven by one of Fowler's compound high-pressure engines, and about 40 16 candle-power incandescents and four 800 candle-power arcs worked in parallel current. Great difficulty was experienced in adapting this plant for the work of the mine, as it was originally supplied for lighting the Globe Theatre, and had been left for several months in the open before being used. The cables, with the exception of a few hundred feet, were all made on the spot, of $\frac{7}{16}$ copper wire procured in the town. Over 2,000 feet were made in this manner. Switches also had to be made in Johannesburg. The whole of the work was carried out by Mr. T. Miles, of Johannesburg."

Strand District Board.—At a meeting of this Board last week Mr. Lemon said there had been a meeting of the Lighting Committee, when they found it was exceedingly important that certain re-arrangements should be made with regard to the agreement which had been entered into with the Metropolitan Electric Supply Company. He asked the sanction of the Board for the erection of another station of supply, so he would move "That the committee be empowered to agree to a supplemental form by substituting a station in Cecil-street for the one in Sardinia-street, and for such other alterations not varying substantially the agreement as the committee shall approve." If this were not done another year's delay would be incurred before they got the electric light in the district. After some opposition the proposition was agreed to. At the same meeting of the Board it was moved that the Board oppose the London Central (Subway) Railway Bill, but after a debate the matter fell through.

The Chancellor of the Exchequer upon the Post Office.—The following notice appeared in the Post Office Circular last week:—"The Postmaster-General has much pleasure in bringing to the knowledge of the officers of the department the following expressions of high commendation which were used by the Chancellor of the Exchequer in his Budget speech in the House of Commons on the 15th instant:—'So far as he (*i.e.*, the Chancellor of the Exchequer) could exercise any influence over the Post Office he should encourage them to improve their service. He should be sorry to take a churlish view of the splendid efforts of one of the most successful departments that ever existed—a department full of energy, which deserved the great thanks of the country for the magnificent manner in which it had conducted a most complicated service.' Mr. Raikes feels sure that this public appreciation by the Government of their labours will gratify and encourage the officers of every rank and class throughout the department."

Field-Telegraph Cavalry Corps.—An order emanating from the headquarters staff of the French army has just arranged the organisation and laid down the duties of the proposed Mounted Telegraph Corps. A telegraph troop, consisting of trained operators, is to be formed in each regiment of cavalry in the French army. The troopers composing this corps are to go through a special course of field telegraphy for twenty days every year at one of the three centres at Versailles, Lurréville, and Lyons; in addition to which they are to be employed on telegraph work when in garrison and on the occasion of the annual manœuvres. In the field every advanced party and reconnoitreing expedition is to be accompanied by portable telegraph apparatus, and the proper complement of operators. The special duty of these telegraphists is to keep up communication with the main body of the cavalry as long as possible, either by heliograph or by means of the existing lines. The telegraphists with the main body have to assist in communicating with those of the advanced detachments and to transmit messages to the general commanding the cavalry division.

M. Cornu on the Incandescence of Shooting Stars.—In a Paper on shooting stars recently read before the Académie des Sciences by M. E. Minary, he argued that the incandescence of these bodies cannot be explained by the transformation of motion into heat. The gases being perfectly elastic bodies, and in the upper atmospheric regions in an extremely rarefied state, heat cannot be produced by the shock of bodies endowed with great velocity and impinging on perfectly elastic molecules capable of receiving the motion and acquiring the velocity of those bodies; in this case the movement is communicated, not dissipated or transformed to heat. The reading of the Paper was followed by some observations by M. Cornu, who remarked that the illumination of the trajectory of the shooting stars might be attributed to a development or a discharge of static electricity without any considerable rise of temperature; as implied by the incandescence of detached particles of meteorites. This would agree with the spectral observations made on the shooting stars, and would lend support to the view that certain cosmic phenomena, such as auroras, the zodiacal lights, comets, solar protuberances, &c., are electric manifestations analogous to those that are so easily generated in rarefied gases.

Milianah (Algeria).—The municipal central lighting station at Milianah (Algeria), which has now been in operation some three months, has proved a decided success. Motive power is obtained from a Meunier turbine which runs at 400 revolutions per minute, and which is driven by a 140ft. waterfall. Two Manchester dynamos, running at 600 revolutions, each supply a current of 210 amperes at 110 volts. The station is situated in a mill on the mountain side, and is a little way outside the town. The public lighting includes forty 20 candle-power and twenty-five 50 candle-power incandescent lamps, besides a few 200, 300, and 500 candle-power lamps. The cost of the plant, cables, and buildings amounted to 55,000fr. The estimated working expenses, including interest and depreciation, amount to 8,000fr. per annum; but as the receipts from private consumers are estimated at 7,500fr., the annual charge for working and maintenance is reduced to 500fr. As, however, the number of consumers is increasing, the station may, on a moderate estimate, be expected to pay its way and light the streets for nothing. Previous to the introduction of the electric light the 56 petroleum lamps lighting the town cost 6,000fr. per annum. The charge for an incandescent lamp is 36fr. per lamp per annum.

Edisoniana.—The following observations are made by our contemporary *Ironmongery*. We quote the passage because we think there is a good deal of justification for the view therein maintained:—

"Nothing succeeds like success, except elaborate and unstinted puffing. A recent issue of the *New York Tribune* contained a contribution to the Edison "boom," which is not only a very characteristic specimen of the well-known style of American journalism, but which comes very near to placing its hero upon a pinnacle quite out of sight of ordinary humanity. Mr. Edison has shown great ingenuity and a remarkable cleverness in promptly utilising the ideas of others, while both he and his admirers, on either side of the Atlantic, are amongst the most skilful advertisers of this pushing age. We fail to see, however, that he is entitled to the honours so eagerly claimed for him, which are the due only of the great original investigators into Nature's secrets; and if there is any truth in the statement which accompanies this last puff, that nearly one-third of the entire space allotted to the United States in the Paris Exhibition is to be devoted to an 'Edison exhibit,' we may admire the enterprise displayed while we deprecate the display. Time will deal justly with Mr. Edison. He will have no complaints to make that a hurrying and indifferent world has passed his genius by unnoticed, and left its recognition to posterity. But we greatly doubt if he will always subtend a third of our interest in the industrial progress of the American States."

Copying Drawings, &c.—A hint that may be useful in engineering drawing offices is given in the *Deutsches Baumgewerbes-Blatt* concerning a new method of copying drawings. Any kind of opaque drawing paper in ordinary use may be employed for this purpose, stretched in the usual way over the drawing to be copied or traced. Then, by the aid of a cotton pad, the paper is soaked with benzine. The pad causes the benzine to enter the pores of the paper, rendering the latter more transparent than the finest tracing paper. The most delicate lines and tints show through the paper so treated and may be copied with the greatest ease, for pencil, Indian ink, or water colours take equally well on the benzinised surface. The paper is neither creased nor torn, remaining whole and supple. Indeed, pencil marks and water colour tinting last better upon paper treated in this way than on any other kind of tracing paper, the former being rather difficult to remove by rubber. When large drawings are to be dealt with, the benzine treatment is only applied in parts at a time, thus keeping pace with the rapidity of advancement of the work. When the copy is completed, the benzine rapidly evaporates, and the paper resumes its original white and opaque appearance without betraying the faintest trace of the benzine. If it is desired to fix lead-pencil marks on ordinary drawing or tracing paper, this may be done by wetting it with milk and drying in the air.

Folkestone.—We hear that the Folkestone Town Council have decided on entering into a contract with Messrs. Crompton and Co. to light the western portion of the town with electricity for five years. The present cost of lighting that part of the town by gas is £1,034. 3s., with 4,312 candle-power, whilst the cost to light the same area by electricity will be £1,032, with 51,600 candle-power. Messrs. Crompton have guaranteed the efficiency of their arc light under very heavy penalties; for it is stipulated in their agreement that, should any of their lights fail, a sum of £62 each should be forfeited—the actual price charged for each lamp being £24. Although the scheme has passed the Council, and has been practically signed and sealed by them, there still remains a difficulty with the Gas Company. Their agreement with the Corporation does not expire until July, 1890; and unless they are willing to allow the agreement to be cancelled or altered Messrs. Crompton's contract will have to be delayed.—At a meeting of the Folkestone Town Council last week the Town Clerk read a letter from the Secretary of the Gas Company, in answer to the request of the Electric Light Committee that the company should surrender the lighting of 200 ordinary, 38 special, and 10 Bray's lamps in the western district of the town with a view to the substitution of the electric light. The Secretary stated that the company was not prepared to assent to any modification of or departure from the lighting contract existing between the Corporation and the company. The letter was referred to the Electric Lighting Committee.

A Dynamo Mishap.—"W. F. G." writes as follows to the *New York Electrical World*:—

"In the operation of machinery of any kind mishaps are liable to occur at any moment; but if we are familiar with the signs and noises that sometimes precede such accidents they may frequently be avoided in time. I was forcibly reminded of this by a mishap which occurred in the station under my charge. The accident was rather unusual, inasmuch as it is the third of its kind to happen among almost seven hundred machines of this type put out. The apparatus referred to is an alternating machine, and had run eleven months without any trouble whatever. A few nights prior to the breakdown we heard a very peculiar noise, which came direct from this machine, and which may be compared to the noise made by a small jet of steam being suddenly turned loose and gradually diminishing to nothing. We could find nothing to cause

Digitized by Google

this noise, and were considerably puzzled over its origin. But when the final breakdown came it was easily understood that the noise was caused by the breaking of a *few* strands of the small wires composing the bands, the loose ends raking over the magnet cores causing the noise described. But when the band proper gave way the result can be more easily imagined than described. The broken band being in the centre, it, of course, caught on the field-magnet cores, and bunched up and stripped the armature of its coils. These coils wedged between armature and fields so firmly as to stop the engine before the throttle could be closed. The only parts of the machine thrown about were small pieces of cardboard and mica used in insulating the coils from the armature. Had I removed the armature on first hearing the noise, I would probably have averted the accident, and I would suggest to readers of the *Electrical World* who operate any type of alternating machine to remove the armature and examine the same *at once* under similar circumstances, so as to avoid serious and expensive accidents.

Fort Augustus.—The following details of the installation at the Benedictine Abbey at Fort Augustus, which was mentioned in our last issue, may prove of interest:—The engine is a 10-horse (nominal) long-stroke horizontal, made by Messrs. Robey and Co., Lincoln, and fitted with Richardson-Rowland patent triple expansion gear, controlled by a Richardson-Nevile electrical governor. The boiler is a 10-horse Cornish one, fitted with Perret's patent furnace for burning dust-fuel. There are 76 Drake and Gorham accumulators, capable of supplying 100 lights for a period of 10 hours. The dynamo is an 18-unit plain shunt-wound Elwell-Parker machine, and by itself is capable of supplying from 250 to 300 lights, so that, with the aid of the accumulators, provision is made for from 350 to 400 lights. The accumulators, when feeding the lamps by themselves, are controlled by the Nevile patent regulator, which automatically keeps the electromotive force in the buildings constant. An automatic switch is also fitted, which connects the dynamo with the battery-circuit as soon as the electromotive force of the former arises above that of the latter; and, in the event of the electromotive force of the former dropping below the required amount, immediately disconnects it from the battery-circuit. There are about 400 lights distributed over the various rooms and offices of the buildings. The majority of the lights are pendants, but in the monastic library and other kindred rooms portable reading lamps are fitted with wall attachments, and in most of the monks' cells and senior students' rooms a pulley arrangement admits of the light being carried to any part of the room. The installation has been carried out by Mr. Nevile, of Wellingore, near Grantham.

Lighting of the Garrick Theatre by the Metropolitan Electric Supply Company.—The Garrick Theatre, which was opened on Wednesday, is lighted throughout by electricity supplied from the mains of the Metropolitan Electric Supply Company, there being in all about 1,000 lamps in the theatre. It had been originally intended to light it from Sardinia-street, but as this station is not ready it was decided to supply the electricity from the engines situated at the Hotel Victoria, which have been discarded on the hotel having been connected to the mains from the Whitehall station. It will be understood that the distance from the Whitehall station to the Garrick Theatre was too great for the supply of the low-pressure current which is there generated. Owing to the very recent completion of the theatre no full trial of the lighting was possible until Friday, the 12th inst.; it was then found that the regulating arrangements of the engines were not sufficient to ensure a steady light throughout the rapid changes required during a theatrical performance. On Saturday morning Mr. J. E. H. Gordon determined to erect an accumulator station at the theatre. For this purpose a workshop was hired in a court behind St. Martin's-lane which adjoins the back of the theatre, and 264 31L cells were ordered from Messrs. Elwell-Parker, together with the necessary switches and regulating apparatus. The total weight of these cells is something over 20 tons. A drawing of the shelves to carry them, which are necessarily of a very massive description, was handed to Messrs. Hobbs, of Croydon, on Monday night, the 15th inst. These shelves, which contain about 10 tons of timber, were completed, put together at Croydon, taken to pieces, sent up and erected and finished by eight o'clock on Thursday morning. The erection of the batteries, which had meanwhile been delivered by Messrs. Elwell-Parker, was then begun, and was completed on Sunday night. They were charged throughout Monday and Tuesday, and were used with perfect success throughout the whole of the final rehearsal on Tuesday night and during the performance on Wednesday. It is believed that this is almost a unique feat in the history of rapid electrical engineering. The result of using the batteries is to keep the light perfectly steady.

Paddington and the Electric Light.—At a meeting of the Paddington Vestry on Tuesday the Electric Lighting Joint Committee recommended that "as the inquiry before Major Marindin, the Board of Trade Inspector, is still being proceeded with, and much valuable information as to the electric lighting is being elicited, any decision on the question of electric lighting of this parish by the vestry be postponed until the before-mentioned inquiry is concluded, and that the solicitor be directed to instruct counsel to present the case of the parish before the Inspector, Major Marindin." Mr. Judge rose to move an amendment. The result of carrying the recommendation would be that the vestry would be driven into a corner, as they were last year, and would be at the mercy of any company which might be most pertinacious in pushing its claims on the parish. It was distinctly provided some time ago that Prof. Forbes should report before the end of March, so that the vestry might formulate action before the May elections. If the vestry undertook the work as recommend by Prof. Forbes it would involve the expenditure of a large sum, and if on the other hand a company introduced the light, a monopoly might be created. Seeing that the matter was so important, he was not satisfied with the manner in which the Lighting Committee had dealt with it, and had given notice of a motion he intended to propose as an amendment. The committee were instructed to consult Prof. Forbes, and he had prepared a report, and upon that report some action should be taken. He thought the course they should adopt was to obtain some proposals from companies for doing the work, as he considered the undertaking too great for the vestry, if they could obtain the same advantage by private enterprise. He would move, therefore:—"That while the report of Prof. Forbes, F.R.S., M.Inst.C.E., shows that the vestry might secure many advantages to the borough by itself undertaking the introduction of the electric light, it would be better to secure these advantages by means of private enterprise, rather than for the vestry to adopt the principle of municipal trading on so extensive a scale." After a long discussion the amendment was lost, and the recommendation of the committee was adopted.

A SONG AFTER LAMPLIGHT.

(As sung by the Swinburnian Gas-share-holder on reading a report of the inquiry now being held as to the working of the Electric Lighting Acts of 1882—1888).

The end has come of all our fume and fretting,
As, darkness deep'ning round us, O my brothers,
We watch this sun of ours sink to its setting
To herald an uprisen light to others.

No more the stream from poisoning meter seething
Shall stay and stint the stifling air around us,
Till it with breath of death, in this our breathing,
Through sense of cheating choke and gasp confound us.

No more! For spite the living load of blunder
That crushes life from every golden measure,
The "main" at length is riven—rent in sunder,
And scattered to the winds its hoarded treasure!

So hail, to fair Electric Installation!
No fear that it will find us mute to meet it.
Invaded, we will yield it habitation
And grovel in our gratitude to greet it.

Hail to its shares! and what, then, of those others?
"*Gas* will go down." Nay, class me not with jokers,
When I advise you, strongly, O my brothers!
To wire that one word "sell" straight to your brokers.

—*Punch.*

THE USE OF THE INTEGRAPH IN DETERMINING SOME PROBLEMS IN ELECTRO-DYNAMICS.

BY L. B. ATKINSON.

The earlier workers in the modern field of heavy electrical engineering for lighting purposes made use to a large extent of alternate-current dynamos, principally, no doubt, because of the difficulties with the commutator which want of knowledge how to design a continuous-current generator gave rise to. It is interesting to speculate whether, had the alternate-current generator continued in the forefront, the modern electric generator would have made the strides it has done; or whether, rather, the double difficulty of dealing theoretically with the magnetic problems and the problems of variable currents would not very seriously have delayed the advance by preventing all but a few professed mathematicians from attempting their solution other than by lengthy and bewildering experiment. As the course of events has gone, however, electricians have grown familiar with magnetic problems before they have been called upon to attack the more complicated questions connected with periodically variable currents.

At the present time nearly all theoretical considerations of the latter subject are based upon the assumption that the law governing the variation of E.M.F. in the circuit is a *simple* harmonic function of the time, and, if this assumption be objected to, the objection is met by reminding the critic that Fourier has demonstrated that any function can be expressed as the resultant of a series of harmonic functions with different periodic

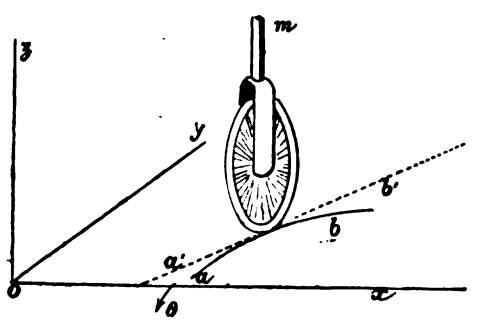

Fig. 1.

times; but writers scarcely stop to see whether their results would not be wholly modified if they considered some of the terms of the Fourier series which they neglect.

Recently, at a discussion at the Institute of Electrical Engineers, Prof. Ayrton gave the result of calculating the current in a circuit acted upon by an E.M.F. following a particular law of variation by a Fourier series taken to nine terms, the result of which was, it may be believed, so far different from what most engineers would have *à priori* guessed at as to convince them of the desirability of arriving at a less tedious, and, probably to most, less impossible, method of solving the problem fully and correctly.

The question that has to be answered is this:—Given an electric circuit of known material and shape, with or without an iron core; given also an impressed E.M.F. varying periodically according to some curve, we can arrive at a solution which will enable us to express graphically, and hence arithmetically, the periodical variation in the current.

If E be at any moment the impressed E.M.F.,
C the current,
R the ohmic resistance of the circuit,
L the coefficient of self-induction,

it is well known that the current at every instant satisfies the differential equation

$$L\frac{dc}{dt}+CR=E \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The object of the present article is to show how this question may be simply solved by mechanically integrating the above equation instead of going to the immense labour of first algebraically integrating it and then working out the numerical values.

Before going right into this, however, it is well first to describe the principle on which such an integrator is based. If a small roller, with a tolerably sharp edge to prevent it slipping sideways, be supported on a horizontal axis, and moved over a horizontal surface in any direction, its point of contact with the surface will trace some curve, and the projection of the plane of the roller on the surface is a line which is at every point tangential to the curve being traced. Thus, in Fig. 1 the roller is supported on pivots, and being travelled over the surface traces some curve $a\ b$ to which $a_1\ b_1$, the projection of the medial plane of the roller, is tangent.

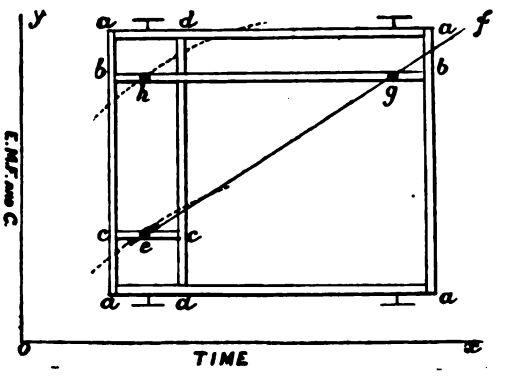

Fig. 2.

Treating this curve by the use of the co-ordinates O X and O Y, if this line, which is a tangent to the curve, makes with O X an angle θ whose trigonometrical tangent is tan θ,

then $\frac{dy}{dx}$ is the instantaneous value of $\frac{y}{x}=\tan\theta$.

Hence, with such a roller, if we know the law of the instantaneous values of the tangents of the angles which its plane projected makes with the axis O X, by *suitably turning the vertical pivot m*, to satisfy this law, we can draw the curve which is required.

It is further to be noted as a property of such a roller that, if it be moved in any direction $a_1\ b_1$, this motion is a resultant of a motion parallel to O X and a motion at right angles parallel to O Y, and that if the pivot m be constrained by guides so that

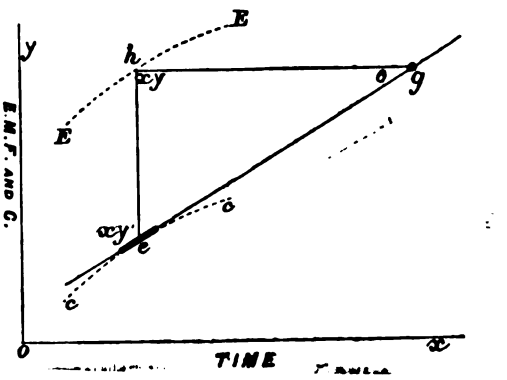

Fig. 3.

it can move in two directions at right angles parallel to O X and O Y respectively, if the pivot is moved parallel to O X, the wheel being inclined at an angle to O X, the wheel and pivot will move on the second guide in a direction parallel to O Y, the reaction between the wheel and paper being the impelling force.

This preliminary explanation is given in order to make what follows clear to any not familiar with mechanical integrator mechanisms; those who are familiar with such will observe that it is the non-slipping class of integrator which is adapted, which has been used to a considerable extent by M. Abdank Abakanowicz and Mr. Vernon Boys in various apparatus.

Proceeding analytically, the construction of an integraph on these principles may now be described, after which it will be

Digitized by Google

shown that the apparatus does satisfy the conditions of equation (1) preceding—that is, that the roller does trace the current curve when the law of variation of E.M.F. is given.

Fig. 2 is a skeleton drawing of such an integraph; $a\,a\,a\,a$ is a rectangular framework carried on rollers constraining it to move only in direction parallel to $o\,x$; $d\,d$ is a cross-bar forming with $a\,a$ an internal frame in which a slide, $c\,c$, can freely move parallel to $o\,y$; $b\,b$ is a bar sliding in $a\,a$, also parallel to $o\,y$. This bar carries at h a tracing-point, and at some point, g, a pivot which can be fixed at any point on $b\,b$, and which is free to move round its vertical axis when so fixed; $c\,c$ carries the vertical pivot of an integrating roller—the head of this pivot is controlled by what may be termed the tiller $e\,f$ passing through the pivot g and free to slide in g.

Referring to Fig. 3, which shows the triangle $e\,h\,g$ dissociated from the framework, the movement can be analysed.

Suppose the tracer h is following some curve $e\,e$ by the component movements of the frame parallel to $o\,x$ and the slide b parallel to $o\,y$, the wheel e traces some curve $c\,c$. At every instant the plane of the wheel projected is tangential to this curve, and the tangent line makes an angle θ with $o\,x$, and the following relations hold good :—

$$\frac{d\,y_1}{d\,x_1} = \tan\,\theta = \frac{e\,h}{h\,g} = \frac{y - y_1}{h\,g}.$$

Now let the curve $x\,y$ represent the relation of magnitude of E, the impressed E.M.F., and t the time to such a scale that $y = \frac{E}{R}$; let also $h\,g$ be chosen to represent to a proper scale the ratio $\frac{L}{R}$,

then

$$\frac{d\,y_1}{d\,x_1} = \frac{\frac{E}{R} - y_1}{\frac{L}{R}},$$

and it is only necessary to write C the current and t the time in place of y_1 and x_1, giving

$$\frac{d\,c}{d\,t} = \frac{\frac{E}{R} - C}{\frac{L}{R}},$$

and transform thus : $L\frac{d\,c}{d\,t} + C\,A = E,$

to show that the curve traced by the roller is the curve of current required.

By this form of integraph, then, all problems connected with a single electric circuit in a non-conducting medium may be solved. It remains to show how, by extending the principle here indicated, the problems of two circuits, each with known electric and magnetic constants, may be treated.

(To be continued.)

MÜLLER AND LAHMEYER'S DISTRIBUTING SYSTEM.

In an editorial note we recently referred to the system of direct-current distribution which was recently brought before the Elektrotechnisch Verein, Berlin, by Herr Lahmeyer. As we find that considerable interest is being taken in the system the following additional details are given: — In Fig. 1 E is the main driving pulley of the engine working the dynamo D, which supplies current to main station leads A and B. From these various feeders are taken off to different points in the network. One such pair of feeders are shown at F, and the object is to maintain a constant potential at the far ends of these feeders, with varying currents, and consequently varying drop of potential along the feeders themselves. To attain this a supplementary small dynamo, driven from E, is introduced into the feeder. The magnets of this machine are compound-wound, as shown in the diagram, the whole current in the feeder passing through the armature and series winding, while there is also a second fine wire coil coupled direct on to the main station leads. The two windings are so adjusted in opposition to each other that when practically no current is passing through the feeder the small dynamo acts as a motor, and by its back E.M.F. cuts down the E.M.F. at F to that required to be kept constant at the

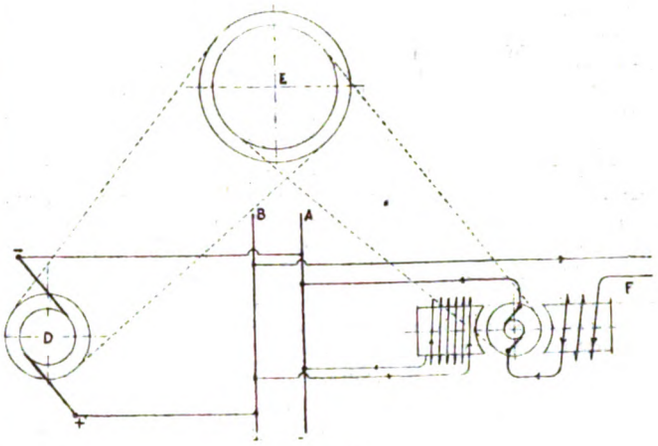

FIG. 1.

distant end. As the current in the feeder increases the series coil comes into play, and more or less neutralising the fine coil lessens the motor action, decreasing the back E.M.F. till at last the two coils balance one another, at which point the resistance of the feeder is just sufficient to reduce the difference of potential at the distant end to the standard value. When the current increases still more the series coils overpower the shunt coils, and the machine then works as a dynamo. Fig. 2 shows

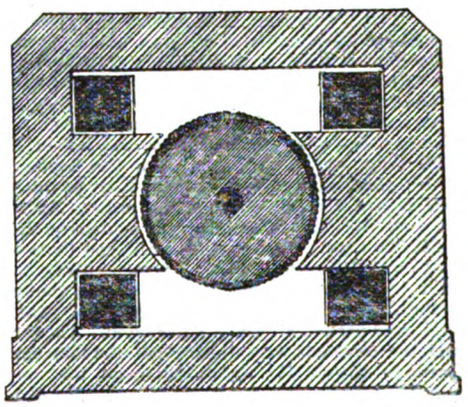

FIG. 2.

the regulating dynamo used by Herr Lahmeyer. As will be seen, it is of the "ironclad" type, the two coils being wound together, not one on each leg as in Fig. 1. The magnets are of cast iron for the sake of economy. The arrangement is said to have been found quite satisfactory at Rostock, where it has been carried into practice.

THE BOARD OF TRADE INQUIRY ON THE LONDON ELECTRIC LIGHTING PROVISIONAL ORDERS.

This Inquiry has been continued at the Westminster Town Hall since our last report. The following gentlemen represented the various parties concerned :—

Mr. Pember, Q.C., Mr. A. K. Loyd, and Mr. J. C. Graham appeared for the London Electric Supply Corporation; Mr. C. A. Cripps for the Metropolitan Electric Supply Company; Mr. Moulton, Q.C., and Mr. R. S. Wright for the Chelsea Electricity Supply Company; Mr. Muirhead for the St. James's and Pall Mall Electric Light Company; Mr. Roger W. Wallace for the Notting Hill Electric Light Company, for the Kensington and Knightsbridge Electric Lighting Company, and for the Westminster Electric

Digitized by Google

Supply Corporation ; Mr. Moulton, Q.C., and Dr. Hunter, M.P., for the Electrical Power Storage Company ; Mr. G. Prior Goldney (the City Remembrancer) for the City of London ; Mr. T. Percy Gunyon (engineer) and two members of the Council for the London County Council ; Mr. C. A. Cripps and Mr. F. M. Jenkins for the Strand District Board of Works ; Mr. Hopwood (solicitor) for the Holborn District Board of Works ; Mr. E. Bayley (clerk) and Mr. G. W. Thompson (surveyor) for the St. Olave's District Board of Works ; Mr. James Spencer for the Greenwich District Board of Works ; Mr. J. H. Horton for the Paddington Vestry ; Mr. Hitchins for the St. George's (Hanover-square) Vestry ; Mr. Wilkins (clerk) and Mr. W. Jenkins (chairman of the Lighting Committee) for the St. James's (Westminster) Vestry ; Mr. Webster Murnane (clerk) for the St. Martin's-in-the-Fields Vestry ; Mr. T. Eccleston Gibb (clerk), and Prof. Robinson, C.E., for the St. Pancras Vestry ; Mr. Cripps and Mr. Greenwell for the Marylebone Vestry ; Mr. H. J. Smith (clerk) for the Lambeth Vestry ; Mr. Harrison (solicitor) for the Bermondsey Vestry ; Mr. E. Moore (solicitor) for the Great Eastern Railway Company ; Messrs. Payne, Son and Pollock (solicitors) for the North London Railway Company.

TUESDAY, APRIL 16.

Major C. E. WEBBER, recalled, examined by Mr. GORDON, said : With reference to previous evidence that had been given as to the laying of mains, what had been meant, he presumed, was that having first, for the minor wants of the street, drawn in one cable, they did not reopen the streets for every 1,000 lamps that were ordered, but simply went to a testing box, put in a main, and drew it through by means of cords. Unless a pipe of inordinate dimensions were first laid down it was attempting what was almost practically impossible except by the system by which each cable had its own separate way. With a number of mains in one conduit it was extremely difficult to draw in additional ones alongside those already in without causing abrasion, or in fact arriving at a complete stoppage by one clinging to the other ; and it was impossible to draw one out of a group of three or four for repair. It would be necessary to draw out the whole mass of cables, which was the Post Office system, but would be out of the question with electric lighting. With reference to the Chelsea Company, they would not have resorted to overhead wires with their uncertain tenure, and, therefore, if they had been unable to get the capital to put down their underground system, they would practically have been obliged to abandon their order.

Cross-examined by Mr. LOYD : When the 1882 Act was passed witness had no measure of the view the financial public would take of clause 27. The Chelsea Company was registered in 1884. According to its prospectus an extension of the time of the 1882 Act was contemplated. In 1884 there was a Committee of Management which included Lord Thurlow, Lord Sudeley, Sir Villiers Lister, Mr. Cunningham, the witness, and one or two others. As to the transformer companies, in his eyes they were offenders ; they wished to rove about the Metropolis and pick out the cream. In 1886 they got their Provisional Order confirmed. That required that there was to be £100,000 appropriated within a year by special resolution, and £2,000 to be deposited or secured within a year in respect to streets in the schedule. It was possible that they had informed the vestry when they got their consent to the Provisional Order that they thought there was no use in trying to raise capital while the 1882 Act remained unaltered. The Cadogan Company threatened competition in 1887. In the autumn of 1887 there were negotiations with the London Company to supply them with electricity. In June, 1888, they promised the vestry to raise £32,000 in five weeks or abandon the order. At that date they had not begun work, but they were extremely anxious to show their *bonâ fides*. Of the £32,000 contracts absorbed £25,313, and there was the building contract of £7,000. The public took up between £10,000 and £11,000. Payments could be made in shares in respect of the contracts. The 13 stations with the 26,000 lights would be sufficient for lighting Belgravia and Chelsea and their portion of South Kensington. The three companies who had made the contracts were to have half the founders' shares. He was not prepared to dispute Mr. King's statement that on the Chelsea system it required £132 500 for batteries alone for 100,000 lights. £108,000 would be required ultimately when they had got the full plant at work, so that the capital of the Chelsea Company would be increased before long to £200,000.

Cross-examined by Mr. C. A. CRIPPS : He had attacked the system proposed by Mr. Gordon for laying down the distributing mains of the Metropolitan Company ; they could adopt, if necessary, precisely the same system as that witness was now proposing. As to three contractors representing the £23,000 out of the £32,000 having the control of the company—if put in that way—it went into the hands of three shareholders who had a majority of votes. There might be great controlling shareholders in the Metropolitan too. Putting aside the contractors witness's company had twenty or thirty shareholders as nearly as he could recollect, but it was a small company, and it was a relative question to the 700 of the Metropolitan. They were not bound down on the question of patents, but were absolutely free.

Cross-examined by Mr. SHIRESS WILL : He was not prepared to tell what motor they were going to use ; it would be decided by Mr. Raworth.

Cross-examined by Mr. HITCHINS : One of the grounds on which the Vestry of St. George's, Hanover-square, had refused to give their consent was that the company proposed to select only the best part of the parish, and that there were three companies willing to undertake the whole parish, They understood that the Metropolitan were applying for the Pimlico part. The Belgrave district was a very scattered one, and the houses were empty for half the year, and it contained few shops.

Cross-examined by Mr. HEWITT : One of the concrete tubes had been taken up in order to see if a 12½ ton steam roller had damaged it, and it was found to be unbroken.

Re-examined by Mr. MOULTON : Two unsuccessful attempts were made to get capital before the Act of 1888 ; after the more favourable terms then given no difficulty whatever was found. Supposing they got these orders they were in a position to carry them out promptly. If the vestry desired a less time than three years they were willing to agree to it. There were very conflicting opinions as to residential quarter being as favourable a ground for electric lighting as shops. Bond-street and Regent-street shops would be more favourable, while Brompton-road shops would be doubtful. This applied to the houses in Belgravia. They would be willing to take the terms of the Metropolitan and the London Company in lieu, but his company's terms were more favourable to the customer.

Mr. MOULTON, Q.C., who appeared on behalf of the Electrical Power Storage Company, said he did not want in any way to go over the ground of the various systems. He was going to confine himself solely to the question of area and opposition with regard to the Electrical Power Storage Company. The company for which he was appearing applied for two areas, one the parish of Paddington and the other a district composed of St. Martin's-in-the-Fields and the Strand. They proposed to take the whole of Paddington, and the system to be adopted is the direct system—that is, direct supply supplemented by batteries, or batteries supplemented by direct supply, according as it is found most convenient. They propose practically to put down mains in every single street in the area, and the time they have limited themselves to is three years, but they would be perfectly prepared to lessen that time.

With regard to the financial position of the company, they proposed to spend something like £30,000 at once in dealing with that compulsory area. Actually devoting your money to works which are of use locally shows that there is a genuine intention to carry out the order. As to the opposition the vestry do not give their consent. The vestry wrote to their company saying they would give the preference to a company that lit Paddington from a station within Paddington. His company fulfilled that requirement, but since then the vestry for some reason or other seem inclined to oppose it and withhold their consent, and it is suggested they desire to do the lighting themselves, but he did not think there was any evidence of their intention to do so. He thought that under the circumstances of his company being prepared to do the work at once promptly and to spread it through Paddington as fast as the demand arose, he should think that nothing could be better for the district than that immediate power should be granted to them, and that the opposition of the vestry ought not to influence the Board of Trade. The Metropolitan Company is the other opposition, and they do not object if they have concurrent powers. He was not going to argue in this speech the relative advantages of competition and districting. His company had applied for a modest area, their terms were better than those proposed by the Metropolitan Company, and he offered a far greater security for doing the work well than the opposing company offered. With reference to the other area—St. Martin's-in-the-Fields and the Strand—the vestry consent. The vestry do not oppose any company coming in, and the question is simply one of districting or competition. The Duke of Bedford opposes, and wants Covent-garden left out of the area. He (Mr. Moulton) did not think if the area was granted any portion of it should be excepted, but that was of course a question for the Board of Trade. He thought that in the district of the Strand, the centre of theatres and places of amusement, the system proposed by his company would be a very weighty recommendation. It would be a most disastrous thing if the lights in a theatre were extinguished, and he should doubt if, under any system than theirs, nothing could occur that would lead to instantaneous extinction, and he would press upon the Inspector very strongly that the direct system with batteries would alone satisfy the requirements of the public supply in a district so peculiarly situated as the Strand.

Mr. JOHN IRVING COURTENAY, examined by Mr. HUNTER, said he was the managing director of the Electrical Power Storage Company, which had 500 shareholders. For the Paddington and St. Martin's orders several of the large shareholders of his company, including Sir Daniel Cooper, Mr. John S. Sellon, and Mr. J. W. Barclay, M.P., and other friends, had agreed to furnish the sum of £60,000 as a minimum amount, £30,000 to be allocated to Paddington and £30,000 to St. Martin's and the Strand. The gas company supply gas at present to 14,864 houses in Paddington, and the number of lights is 112,770.

Cross-examined by Mr. PEMBER : The capital of the company is £200,000, of which £149,000 odd is paid up. He did not think the demand for light in Paddington would be so great as some people thought. There was a large population. He thought the shopkeepers would want the electric light, but he could not say if there would be room for two companies.

Cross-examined by Mr. HORTIN : The area they had taken in Paddington was, he hoped, the best. He knew of a most suitable place for a station along the Canal, but he must be excused from mentioning it. He did not approve of the kind of competition proposed. He was aware the parish of Paddington had been considering the question of doing the electric lighting themselves, but he was not aware they were contemplating doing it. He thought £30,000 was sufficient to carry out the proposed compulsory work at first. He would be surprised to hear that the Westbourne part alone would take four or five times that amount.

Mr. FRANK KING, recalled, examined by Mr. HUNTER, said that in his order in that part under Schedule A he was bound to put down mains ; and although no requisition might be made in that part under Schedule B, they were bound to supply under requisition. In the first instance he would lay down plant sufficient for 10,000 10-candle lamps, for which £30,000 would, he thought, be amply sufficient. The £2. 8s. per running lamp estimated expenditure under his system would be at the most economical limit, and he had allowed a margin leaving it at £3 per lamp.

Mr. RUSSELL GRIFFITHS, in addressing the Inspector on behalf of the Commissioners of Sewers for the City of London in opposition to the London Company and the Metropolitan Company, gave the history of the Commissioners of Sewers in relation to the lighting of the City of London and said he proposed as little as he could to contrast the relative advan

Digitized by Google

tages of the two styles of creating and supplying electric light which had been detailed by so many witnesses. He was quite content to take what his friend Mr. Moulton had said with regard to the difficulties the alternating system would have to deal with. He submitted that the 10,000 horse-power proposed was an entirely unsafe power, and the way in which the supply was to be brought into London from the Deptford Beckton, as it had been called, was a source of danger; there was no reserve of power, and it would be quite unsafe for the City of London to depend on a supply so exposed to damage either by accident or design in the way it was brought in. The jointing also he thought was particularly liable to get out of order. There had been evidence that transformers did not always do their work, and it might be possible for the high voltage in the mains to get into a house. They had heard of the accident to the Pittsburg gentleman arising from a voltage of 1,000; therefore, if anything did happen to the transformer that it did not do its duty there would be great danger to the inhabitants of a house. Another thing about the alternating system was the fact that no motor had yet been discovered for it. On the question of competition in the City he thought it would be highly inconvenient, not to say impossible. He thought there would be no hardship entailed upon the citizens of London or upon the respective undertakers if they did not get their Provisional Orders this year, because practically the citizens would be safe in the hands of the Commissioners of Sewers, who were really trying to do the best they could for the constant future electric lighting of the City, and the Provisional Orders, however beneficial they might be to the companies who have promoted them, are not beneficial to the public at large. After he had called his evidence he should ask the Inspector to say in his report to the Board of Trade that there were special reasons for not including in the Provisional Orders the area of the City of London. He could assure the Inspector that the Commissioners did not desire in any way to stop the extension of electric lighting, that they really wished to foster it with a paternal hand, but they did not want such conditions imposed upon them as were proposed by these particular orders.

In the course of Mr. Russell Griffiths' speech the Earl of Crawford and Balcarres was called to clear up one or two points on the capital of his company, the estimated number of lights, and the cost of laying distributing mains.

WEDNESDAY, APRIL 17.

Mr. HENRY BLAKE, examined by Mr. RUSSELL GRIFFITHS, said that he was the principal clerk to the Commissioners of Sewers. The Commissioners of Sewers had spent £12,519 upon electric lighting during six years. Under the contract made with the Edison Company, which was to have commenced on the 1st February, 1882, it was arranged to use certain subways in the Holborn-viaduct. Later there were negotiations for a contract with the Brush Company. As to the lighting of the City in the past, in 1823 the price of gas was 15s. per thousand; in 1849 it had fallen to 5s. and to 4s. There was no map in existence now showing all the sewers and pipes under the City streets. The 1885 map contained all that were known. The Hydraulic Power Company had since put down pipes. In the Edison contract the City would not interfere with the company supplying private lights. So far as the witness knew the City was in effect practically treated in the same way with regard to gas lighting that other parts of the metropolis were.

Cross-examined by Mr. PEMBER, the witness said he could not point to anything in the Electric Lighting Acts of 1882 or 1888 which excepted the City of London from the general operation of the Act.

Mr. PEMBER said that he should argue when his time came that with regard to the Electric Lighting Acts the City was as much open as a district over which a Provisional Order can be given as any other part of Great Britain.

Cross-examination continued: The principal duty the Commissioners kept before them was the matter of street lighting, being also desirous of giving the citizens the benefit of the new light under guarded conditions. As to their conditions being in conflict with the Electric Lighting Acts of 1882 and 1888, witness did not think they were. He did not think that Clause 29 was in conflict with the spirit of those Acts. Clause 36, as to the reduction of price after a 10 per cent. dividend, was no doubt to some extent framed upon an analogy to the sliding scale in the Gas Acts.

WITNESS continued that he was not aware of a clause of that class being rejected by the 1886 Committee. No doubt the power to purchase in 42 years constituted a very material difference in the position from that of a gas company which had got its works for ever. As to the duration of the public lighting contract for 21 years, he did not think that interfered with the provisions for private lighting. As to the Commission having at the end of 21 years the option to renew the public lighting contract for a further seven years, the companies were not obliged to enter into this contract.

No, but they are obliged to tender under this specification?—Yes. As to the event of the contract having involved a loss to the contractor, and his being forced to renew it for seven years, witness thought he might trust a body like the Commissioners.

Now will you let me read Clause 40 to you:—"Power is to be reserved to the Commissioners to acquire the undertaking and works by purchase at the end of 21 years."—Well, if the company choose to contract themselves out of the Act.

Now we have got it that you do, on behalf of the City, claim in this specification power to divide the whole of the Electric Lighting Act by two?—We seek to get the contract on these terms. The power to determine the contract in the case of failure, the witness continued, was to guard against failure.

Mr. PEMBER then put the case of bad feeling arising between the company and the Commissioners; in a fit of anger the Commissioners, the learned counsel said, might immediately order the removal of all the mains and conductors.

Mr. RUSSELL GRIFFITHS: That is all right.

Mr. PEMBER said he would rather put his faith in writing than trust to the temper of a public body or an individual.

The WITNESS: You know there are 95 Commissioners.

Mr. PEMBER knew that, but there was only one engineer, and there were generally one or two belligerent spirits. However, that was the effect of the clause.

WITNESS continued that under Article 39 all the districts might go into one hand, but there were only two or three companies apparently capable of doing that. The engineer had reported to the Commissioners on these orders. Mr. Preece had advised the Commissioners, and he had been very instrumental in arranging the specifications.

Re-examined by Mr. RUSSELL GRIFFITHS: These specifications were for private contracts with the Commissioners, and did not pretend to be under the Act.

Mr. WILLIAM HENRY PREECE, examined by Mr. RUSSELL GRIFFITHS, said he was the electrician to the General Post Office. He had advised the Commissioners of Sewers since 1882. There were 24,983 inhabited houses in the City, the residential number of persons being 261,061; during the day the population would be something over a million. He estimated the present number of gas lamps in houses throughout the City at 622,000 for ordinary private purposes. The public lamps were 3,136, and were lighted at a present cost to the Commissioners of £10,530 per annum. The light was required for private purposes up to about seven o'clock, but there were the printing offices, where it was required all night. It was, of course, extremely difficult to form any accurate estimate of the number of hours of lighting a place like the City, and the only illustration he could get to draw a conclusion from was the central station of New York—the Edison Company's, in the neighbourhood of Wall-street, somewhat similar to the district of the City, and when he was in America in 1884 he took a good deal of pains to arrive at a fair conclusion as to the average number of hours per lamp to-day, and it came out at 2¼—2·4 hours per day: that would be 876 hours per annum for City purposes, offices, restaurants, &c., for private lighting. The latitude of New York was 41, and of London 52, which would make a difference in the daily average of artificial lighting of an hour, which gave 3·5 for London. He doubted whether it was fair to draw any comparison whatever between the private lighting of residential districts like Kensington and Wimbledon and the City. Mr. Crompton put the apex of the curve of light at Kensington at a little after seven o'clock, and the principal demand from five to seven in winter.

Would it be possible, do you think, if a company supplied largely the residential part and the shops and the theatres in the West End that they could also in the four winter months, say, supply the City at the same time?—Witness thought they would overlap very much, and the consequence would be that if they started with too small a plant for the ratio of the demand in the City their supply would rather diminish. With additional machinery standing idle the effect of its running light would be very uneconomical. The public lamps in the City were spread over 46 miles, which gave for a double main 92 miles, and if there were two competing companies 184 miles. There were 13 miles of main streets, 6½ miles of second class streets, and 13¼ of third class streets, and of courts and alleys about 12¼ miles. To replace the existing gas lamps witness estimated that it would require about 500 arc lamps of 500 watts and about 1,000 glow lamps of 25 or 32 candle-power. The number of hours the public gas lamps were lighted in the City averaged 4,300 hours per annum. As to the number of lamps that would probably be required for private lighting in the City, witness thought it might fairly be assumed that in the competition that must take place between electricity and gas, of the 622,000 gas lamps he had mentioned they would probably get one-third, say, 210,000 for glow lamps. That would be about 70,000 for each of the three districts of the specification map. The Post Office installation was put up under the superintendence of the witness, and there the cost of lighting per unit—that was the unit they had in the Electric Lighting Act—was 3½d. They used Willans and Robinson's engines, old type—not so economical as those of the present day, which, if introduced, he thought, would reduce the price per unit to 2½d. The price mentioned was simply cost of production—nothing for interest on capital. He quite approved of the City specifications. He thought the Deptford proposal a gigantic experiment.

As an electrician, will you tell us the grounds on which you form that opinion?—Yes. Generally I may say this—that I am a decided advocate for the distribution of electricity over extended areas by means of alternate currents and the transformer system, and I consider the question of concentrating all your eggs in one basket, as the London Electric Supply Company have at Deptford, or distributing your central stations over the metropolis, as other companies propose to do, is simply a commercial question—a question of pounds, shillings and pence. There has been ample evidence given here of reasons *pro* and *con*, and if a balance-sheet were struck between those reasons I think myself that it would be found that they balance each other very fairly. But my objection, the strong objection that I feel to the scheme of the London Electric Supply Corporation, is not a question of their central station—for I believe that has been perfectly worked out—but it is the connection between Deptford and London by means of their mains. The question does not seem to me to have been at all solved by Mr. Ferranti, and I regard the proposals that have been submitted to this tribunal as regards the mains as very objectionable indeed. I think the form of main proposed by the London Electric Supply Corporation is not in consonance at all with the rest of their scheme, and it is a very weak point, and one that will require further and more mature consideration. He anticipated great difficulties—difficulties of insulation, of joints, and of disturbance to contiguous telephones and telegraphs. He had not seen any motor to which could be applied all the energy produced by the alternating system. There were two or three spoken of as existing; there was the Tesla, but

Digitized by Google

it was not on the market yet. There were direct system motors on the market. There would doubtless be a large demand for motive power in the City. As to the subdivision of the City into three districts, the main reason which had guided the Commissioners of Sewers, and that certainly guided witness in recommending it, were to give the public the benefit of competition, at the same time avoiding the cutting up of streets by rival companies. Holborn, Newgate-street, Cheapside, Fleet-street, were now almost choked by pipes. The Post Office had from 15 to 20 down Cheapside, and he did not think it would be possible to lay a new 6-inch main down Cheapside; in fact, they had been compelled to go along some of the bye streets. Two companies in one district would sooner or later amalgamate. With the City divided into three districts the fear of competition would maintain a good service. As to the model of the mains shown by the London Company, there was no counting on the outer sheath of copper; it was admitted, he thought, by Lord Crawford and Mr. Ferranti that they proposed to insulate the outside conductor, and that the question of insulation was simply one dependent upon some mutual arrangement between the company and himself. With regard to insulation and leakage, as far as danger to persons was concerned, he thought there could be no more effective mode than that suggested by Mr. Ferranti. If the outside conductor were buried in earth or in contact with earth he did not think there would be danger of shocks to persons, but the telegraphs would suffer. His opinion was that with the outside to earth all the telephones in London would be affected with 10,000 volts. As to the maximum price proposed in these orders, 8d. per unit, they were in a regular wave of progress tending towards economy; during recent years the cost of dynamos had been diminished by at least one-third, the output of the dynamos themselves had been increased at least three times, so in that one item alone we were now nine times better off than off five years ago. He did not anticipate that there would be the same advance in the future, but an advance probably.

Cross-examined by Mr. PEMBER: The electrostatic induction from the cable between Deptford and London depended upon there being a curve between those two places; if they could get an absolutely straight line it would not be set up, but earth conduction would. He was not aware that an experimental main insulated for the express purpose of meeting the conjoint objection as to the safety of the public and the burying of the uninsulated main in the earth was being laid. He had no doubt whatever that a cable could be made which would get rid of the Post Office objection. When that was done his objection to the Deptford scheme vanished. He had certainly not any doubt that a motor could be found which could be adapted to alternating currents. With those two points excepted he had nothing to say against the scientific aspect of the scheme, leaving out the question that the Board of Trade undertook safety to life, and, as far as the Post Office was concerned, safety to telegraphs. As to the statistical part of his evidence, the 622,000 gas lights in the City were arrived at in this way—a certain number of houses were taken and the number of lamps counted, and it came out that the average number of burners per house was 25, and multiplying the number of houses by 25 brought out something over 600,000. Then the quantity of gas consumed supplied to the City for private lighting purposes by the Gas Light and Coke Company was taken and divided by the average consumption per burner, and the two together were found to bring out that figure very nearly, so that the 622,000 was taken as a mean. As to the benefit of competition to the public, that would be secured by the three-district principle, from there being a marauding individual close by ready to pounce upon other preserves if the service there were not properly rendered.

There is just one other point. I do not think I need really discuss it with you, because Parliament has already discussed that, but, if you were acting as consulting engineer to an electrical company like the London Electric Supply Corporation, would you advise them to tender on the basis of being ousted in 21 years and having all their undertaking bought up?—Yes. Mark you, it is a purchase by agreement. It is not a compulsory sale.

Let us have a look at that. Provided it was by agreement with arbitration you would not mind?—No.

You would not advise them to submit to the purchase clause in these specifications, as contained in clause 40, I believe: "Power is to be secured to the Commission to acquire the undertaking and works by purchase at the end of the twenty-one years, or each succeeding seven years, on giving six months' notice in accordance with section 2 of the Electric Lighting Act, 1888." That is not agreement you know?—I do not know what section 2 of the Electric Lighting Act of 1888 is.

Just look and see whether you would like that.—After referring to the section: I was not responsible for that clause.

Re-examined by Mr. RUSSELL GRIFFITHS: With Mr. Ferranti's precautions the dangers to the individual from the Deptford main would be reduced to a minimum, which would not increase the difficulties of the insulation against disturbance to telephone and telegraph wires.

Examined by Major CARDEW: With reference to this question of interference with telephones, is not it the case that, assuming the proposed main to be earthed at Deptford, and also, say, to be earthed at the distant end, the inequality in the currents in the two conductors thus produced would cause an interference with telephones from current induction?—Yes.

In addition to that there would be a certain interference with telephones from electrostatic induction, which is a different thing?—Yes.

But if the earth can be kept to the generating point, there is no reason why there should be any current inductive effect?—As long as the insulation is perfect.

Mr. RUSSELL GRIFFITHS said that this closed the evidence on the part of the City of London.

Mr. SHIRESS WILL, Q.C., M.P., in opening the case for the House-to-House Supply Company, said that the company was located at South Kensington, having a station at Lillie Bridge on a site between the railway and the Brompton Cemetery. There were at present three engines there, each set of plant being capable of supplying 4,000 incandescent lamps, and completed stations would contain twelve such sets. They were tied to no system, but had commenced with the high-tension alternating-current converter system. He advocated districting. The whole difficulty in this country up to now in the way of house-to-house lighting had been not a scientific one: the commercial difficulty had been entirely the cost of the mains, due to the battery system and the low-tension system, of course. That was to say, in order to carry a current of low tension of 100 volts you would require a main of 400 times the size of the one to carry 2,000 volts. The disadvantages of the plan of Mr. Moulton's company were the rent, &c., of the thirteen stations, and of Mr. Crompton's the loss from the use of accumulators. The system proposed by the House-to-House Company was in use at Brighton and Eastbourne. He did not think that the motor question affected the Kensington area beyond being a small matter. He said that small compact companies located in the particular district assigned to them would be the best safeguard for efficient lighting.

Mr. ROBERT HAMMOND, examined by Mr. SHIRESS WILL, said that he was the managing director of the House-to-House Company, chairman of the Brighton and Hove Electric Lighting Company, and managing director of the Eastbourne Lighting Company. The nominal capital of the House-to-House Company was £350,000, of which £41,600 had been subscribed. He thought that the standard price should be fixed at the expiry of the first seven years, based on a 10 per cent. dividend.

Cross-examined by Mr. WALLACE: The 6½d. cost of production per Board of Trade unit at Brighton was high on account of the smallness of the works. What do you anticipate you will be able to charge for electricity? What do you propose to charge under your order for the current?—We propose to charge a sliding scale, which I hope some day will be universally adopted. We make a sliding scale depending upon the number of hours a man uses his lights. We ask him to fix his maximum supply demand, and we do all we can to encourage the continuous use of that number of lights, whether it be 10 or 100. We charge upon the sliding scale upon this basis, that for the first 100 hours per quarter of his maximum supply demand we charge 1s.; the second 100 hours 8d., and all beyond 4d., so that if he is a man who uses it five hours per night he gets it very cheap indeed. Witness continued that the customer fixed his maximum number of lights and a converter was put in accordingly.

Mr. WILLIAM LOWRIE, examined by Mr. SHIRESS WILL, said that he was engineer to the House-to-House Company. At Eastbourne the voltage was 1,900, at Kensington 2,000. At Eastbourne they had always succeeded in keeping a high state of insulation. At present they supplied 500 lights in Kensington, the Parker-Lowrie dynamo being used; the unit of horse-power fixed there was 200.

Cross-examined by Mr. MOULTON: In practice it would be difficult to say whether it would be exactly true that direct mains would be 400 times the size of high-tension mains.

Major MARINDIN: He said theoretically. Under similar conditions it is right.

Prof. FORBES was recalled as to tests he had made at the West Brompton station under very severe conditions, and he found the parallel working there succeeded in a way that was absolutely unexceptionable in regard to switching on a dynamo: there was not the slightest flicker.

THURSDAY, APRIL 18.

Prof. WILLIAM CROOKES, Chairman of the Notting Hill Electric Lighting Company, examined by Mr. WALLACE, said his house had been lighted by a private installation for the last seven or eight years, and friends of his had united together to form a small company to try to introduce the light into the neighbourhood. Up to the present time they had only raised a small amount of capital for the purpose of the preliminary expenses of the concern, and they had not made any effort to get the money from the public or do anything more than arrange to find the necessary capital as soon as it shall be required. The nominal capital of his company was £100,000. He considered it was a private company, not got up with any particular object of making profit but simply to introduce the light. They had not actually bought the sites at the present moment, but they had two and probably three sites in a very good position, which their consulting engineer had seen, and they were in treaty for them. His company were before the Vestry of St. Mary Abbotts, Kensington, with other companies for about twelve months. Speaking of the Notting Hill Company the vestry reported:—"This company has not yet called up any capital or constructed any works, but your committee are satisfied that it is a *bonâ fide* concern, well supported both by engineering talent and by gentlemen of local influence, and believe that if a Provisional Order is granted the company will at once apply itself to carrying out works in the district assigned to it."

In answer to the INSPECTOR the WITNESS stated that the directors had each taken 15 shares of £10 each, which was sufficient to carry on the expenses. There were Articles of Association, and everything had been done in the regular way.

Mr. WALLACE then addressed the Inspector on behalf of the Kensington Court and Kensington and Knightsbridge Electric Light Companies. He said that the Kensington and Knightsbridge Company is one that has been in existence for about a year and a-half, having bought the undertaking of the Kensington Court Electric Light Company. The two companies now ask practically for the same order. The Kensington Court Company were in possession of the licenses granted by the Board of Trade, and the Kensington and Knightsbridge Company, taking over the Kensington Court Company, thought it advisable to apply to the Board of Trade in the name of both companies in case there should be any technical difficulties arise as to the transfer of property from one company to another. There are two stations in that area, one situated at Kensington

Digitized by Google

Court, on the property lately belonging to Baron Grant, and the other situated in Chapel-street, on the north side of the Brompton-road, the whole area being one square mile. He asked for a small portion of the Chelsea Company's district, a small piece from the House-to-House Company, and a small portion up in the corner near Wright's-lane, down which his company had already laid their mains. These were the only alterations he asked the Inspector to make in the boundaries as allocated by the vestry. He did not wish in any way any further than he could help to go over the ground that had been traversed so frequently during the course of the inquiry by other promoters, but he thought there was a slight difference between the policy advocated by the Kensington and Knightsbridge Company and the policy advocated by the promoters of the other schemes. He thought he might divide the principles proposed by the promoters of these various undertakings into three: There were those who desire to have concurrent powers over the same area, there were those who believe in districting it, and there were those who thought that the promoters of the different undertakings and the capital of the undertakings should be as far as possible within the district itself, and that the stations should be situated close to the area of supply—that the local people in the district, the consumers themselves, should find the capital necessary to carry on the works from which they obtain their current, and that the district should be lighted from stations in the immediate vicinity. With regard to concurrent powers, he thought it necessary to mention that in his district they had streets very similar to the streets that have been spoken of by the local authorities for the Strand. High-street, Kensington, was a very narrow thoroughfare, and the traffic was in fact congested to a very great extent—there was the same class of mains there that is found in the Strand, not only gas and water mains but telephone and telegraph mains. As far as the mains of his company were concerned it would be a serious thing for them if the mains of competing companies were allowed to come down their conduit, because their mains were not insulated at all. Up to the present his company had not made any arrangements for having a military man upon its directorate, but the other companies had already provided themselves with generals in order to take part in their battles. As to what the result of competition would be, he thought Mr. Moulton had put before the Inspector much better than he (Mr. Wallace) could. It would not manifestly do to allow those companies which are advocates of districting to be interfered with by an outside company such as the Metropolitan, which would, according to its proposals, interfere with the Kensington and Knightsbridge portion of the Knightsbridge district. In so doing there would not be a fair test, and nobody would be able to judge hereafter in the event of the failure of either company what the cause of that failure was; and he would suggest that the Board of Trade should allow all those companies that have proposed to light an area by themselves to have that district, and that it could then be seen what they were able to do without competition. With regard to the work that has been done, the building has been erected and the boilers put in, and in about a month's time electricity will be supplied from the Knightsbridge station. At the Kensington Court station they had been at work for the last three years. They had Babcock's boiler, Willans' engines, and Crompton's dynamos and batteries, the batteries being used only for the purpose of giving a limited supply of electricity in case of the breakdown of the engines. With this system you can stop the works, properly examine the engines, and in the case of anything going wrong with your boiler or anything of that kind, you can rely on your batteries while such temporary work and alteration is being made. With regard to the smoke nuisance he thought his company had got over that difficulty by using Welsh coal and keeping the exhaust steam separate from the smoke. As to vibration, they used the Willans engine, and if the Inspector visited the works he (Mr. Wallace) thought it would be seen that no nuisance was likely to arise on that score. In conclusion, Mr. Wallace having enumerated the places now lighted by his company, said that from the commencement of their endeavour to meet the public wants, now three years ago, they had not had any failure in the light except on one occasion, and that was when a machine broke down, and he thought that was a record that no other company appearing before the Inspector at present could furnish.

Mr. ROBERT STEUART ERSKINE, examined by Mr. WALLACE, said he was the secretary of the Kensington and Knightsbridge Company. The company was first started in 1886, under the name of the Kensington Court Electric Light Company, with a capital of £10,000, as an experiment one, with the object of working Kensington Court. There has been no public subscription, all the money having been found by the directors and their friends. The present capital is now £37,000, all paid up with the exception of £500. There is a considerable amount more promised—about £75,000—which will be available as required. There are six sets of 180 horse-power engines on order at the present time for delivery in the summer for next winter's work. They had been lighting part of the Town Hall, Kensington, for about a year—the council-room, the board-room, and a few other parts. There was a considerable demand for light in the district, and they had guaranteed to commence supply by the beginning of May under the 1888 license. There has never been any nuisance at either of the two stations that they have not been able to meet at once and within a day or two put right. No dividend had been paid as yet, but they were working at a profit now. At first they made a loss, but last year they turned the corner, finished with a profit, and wiped off the previous losses. They were getting a fair number of houses to light, but the number in a street was so small that it would not pay two companies to lay down mains for them.

Cross-examined by Mr. C. A. CRIPPS, counsel for the Metropolitan Electric Supply Company: The whole amount of the paid-up capital within a small amount had been expended. He could not say what the bank balance actually stood at at present. They never had a big balance at the bank as the amount paid up was immediately spent on plant and mains. He thought they had one distributing main of rather over half an inch sectional area. That was the largest, but most of them were a quarter of an inch—between a quarter and half an inch, and some under the quarter.

Cross-examined by Mr. BRANDRETH: He believed they had included Stanhope-gardens. He was aware that was more than half a mile from the station, but there would be a battery station within a very short distance. He knew the vestry especially wished to have one of the storage systems introduced into the parish.

Re-examined by Mr. WALLACE: The site chosen at Knightsbridge is the only available site that they could find anywhere for their purposes.

Mr. FRANCIS RADFORD, called, examined by Mr. WALLACE, said he was one of the directors of the Notting Hill Electric Lighting Company, and resided in the district. He was a large owner of property in the district, and he and others were the trustees for over 50 houses in Holland-park. He thought there would be no difficulty in getting the necessary capital in the event of their getting the Provisional Order if the other directors were of the same mind as he was. Personally he saw no difficulty about capital.

Mr. ALBERT EDMUND LOUGHBOROUGH, the solicitor and Parliamentary agent, was called and produced the Articles of Association of the Notting Hill Company, and read the names of the subscribers thereto as follow: Sidney Water, 24, Ladbrooke-square, W.; James T. Jarvis, F.R.G.S., 30, Ladbrooke-square, W.; William Crookes, 7, Kensington Park-gardens; Joseph Crookes, 7, Kensington Park-gardens; Alexander Howden, 72, Holland-park; Francis Radford, 26, Pembridge-gardens; and Aston Webb, 13, Lansdowne-crescent, W.

Major MARINDIN: Are there any other shareholders?

The WITNESS: There are no other shareholders.

Mr. WALLACE then addressed the Inspector on the Westminster Company's case. In the course of his speech he said the company have a site already at Victoria-mansions belonging to one of the directors of the company, and they have placed their boilers down there and ordered plant from Messrs. Crompton which, in the course of the next few weeks, would be able to supply about 5,000 lights in the immediate district. The whole available land is about half an acre in extent. It was not proposed to be used as a permanent station, but would afterwards be used as a battery station. In the meantime, as the demand was not very large, they proposed to go on lighting from there at present. The only difficulty the Westminster Company felt was the supplying of Mayfair, which was a considerable distance from either of the stations. They proposed to have a battery station within the area of Mayfair.

After a discussion as to procedure,

Major MARINDIN: Then if there are no objections I should propose taking the vestries in the order in which they come, beginning with the objectors to the London Supply scheme.

Mr. LOYD: If you please, sir.

The following vestries have dropped out as far as the London Company is concerned:—Chelsea, Greenwich District Board of Works, St. George the Martyr, Southwark; Paddington; St. John's, Hampstead; St. Luke's, Middlesex; Rotherhithe; St. Mary, Islington; St. Olave's, and Shoreditch.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, April 26th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "Photography for Engineers." By C. H. GALE and V. W. DELVES-BROUGHTON, Students Inst.C.E.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at the St. James' Hall Restaurant.

TUESDAY, April 30th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "The Italian Renaissance Painters: Their Associations." By JEAN PAUL RICHTER, Ph.D.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Discussion on "Armour for Ships." By Sir NATHANIEL BARNABY, K.C.B. Paper to be read, time permitting, "The Treatment of Steel by Hydraulic Pressure." By W. H. GREENWOOD, M.I.C.E.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. "The Northern Waterway to Siberia." By Capt. WIGGINS, F.R.G.S.

WEDNESDAY, May 1st.

ROYAL INSTITUTION.

1:30 p.m. Annual Meeting.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary General Meeting. Inaugural Address by the President, Mr. CHARLES COCHRANE.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Secondary Batteries." By W. H. PREECE, F.R.S.

THURSDAY, May 2nd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "The Science of Animal Locomotion in its Relation to Design in Art (Illustrated by the Zoopraxiscope)." By EADWEARD MUYBRIDGE.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary General Meeting. "Research Committee on Marine Engine Trials: Report upon Trials of the s.s. 'Meteor.'" By Prof. A. B. W. KENNEDY, F.R.S.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and now makes over 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY.

CONTENTS OF THE CURRENT NUMBER.

THIS YEAR'S EXHIBITIONS.

At least two Exhibitions of considerable importance to the electrical world are to be held during the present year, and for some time past their preparations and prospects have been watched with some anxiety. It cannot be denied that misgivings were at first entertained with regard to both of them, the one in the French capital having too much the appearance of a political demonstration, and the other, in Birmingham, seeming too like a feeble attempt at rivalry on purely industrial lines. If the Paris Exhibition did not attract visitors it was hardly likely the English Exhibition would succeed any better; and if, on the other hand, Paris was to be a success, there would be small chance for Birmingham in the same year. So it appeared when these projects were first mooted. But as the preparations have advanced all apprehensions of this kind have gradually disappeared, the most encouraging accounts reaching us from both places with regard to the result of the undertakings. At Birmingham, where the Exhibition, which is to be held in Bingley Hall, will be largely of an electrical character, demands for space are already threatening to exceed the limits assigned to it, although the show will not be opened

Digitized by Google

until the month of August. Efforts are being made to secure representative exhibits from all parts of Europe and America; and from what we hear about it there is good reason to expect a collection of electrical appliances such as has never before been brought together in one place. A novel feature of the Birmingham Exhibition will be the working of the whole of the machinery employed in the building by electrical power. Although the Exhibition is to be styled "Electrical and Industrial," electrical interests, both scientific and commercial, are strongly represented on the Committee; and if they are adequately supported a very distinctively Electrical Exhibition will be the outcome.

At the present juncture in the affairs of electrical industry the success of the Birmingham Exhibition is much to be desired, as it cannot fail to exercise considerable influence for good or evil on the electrical engineering trade of this country. We certainly do not fear competition from France, or from perhaps any other Continental nation to be represented at the Paris Exhibition. As regards America, if we do not speak with the same confidence it is rather because of a prevailing prejudice than from any doubts as to the superiority of British manufacture. We have none whatever as regards British science; and if our inventors and makers are keeping pace with it the display at Birmingham ought to set the tide in favour of this country even among visitors from the United States, who, it is expected, will cross in vast numbers. This circumstance is one on which the managers at the Midland capital are to some extent reckoning for the success of their venture. That Exhibition will not open until the one at Paris has got well advanced; and the crowd of travellers who are certain to pay this country a visit on their return journey will, many of them, not neglect to take a peep at what we have to show them at Birmingham. It will be our own fault if we do not profit by the coincidence, instead of suffering by it, as was at first feared.

At the Paris Exhibition we shall hope to hold our own notwithstanding the national jealousies which are never wanting in the French capital, and the extravagant preference which appears to have been shown to rival exhibits from the other side of the Atlantic. Mr. Edison is, of course, very much to the fore as usual on these occasions. All we need say about it to his English competitors is that if they are content, as he would say, with a back seat, they cannot blame him for sitting in front. Many of them, perhaps most, do not believe in the great magician; and did they speak their minds he would not be flattered if within earshot; but somehow it happens that they fail to assert themselves, and allow the likes of him to be taken at his own estimate. It is, perhaps, too late to mend matters now, but not too late to take a lesson for future guidance. One other reason, of a quite different complexion, will probably contribute to the preponderance of American Electrical Exhibits at Paris. For a good while the English manufacturers were shy about taking part in the show, and had to be whipped up with a vigour which would not have been needed at any other time, and which after all has been only partially successful. What the British Government declined to do, naturally British subjects hesitated to do; and the only consolation we have is that we are not singular in this respect, the Americans alone taking the Exhibition seriously or with any show of hearty appreciation.

With, however, the promised influx of numberless sightseers from the States—and perhaps also the retirement of General Boulanger from the scene—the political character of the Exhibition has gradually faded out of sight, and unless rudely reminded of it by the Parisians themselves their foreign visitors may come and go without realising that the fête ostensibly commemorates the taking of the Bastile in 1789. Judging by the preparations now being made for their transport there will also be no lack of English visitors, few of whom have much sympathy with the French Revolution, and many of whom regard it as the greatest calamity of modern times. The Exhibition managers as well as the French Government have, however, discreetly held their tongues about it of late, fearing, perhaps, that a practical repetition of the event by way of centenary would contribute as little to the success of the Exhibition as to the safety and comfort of their guests. It is to be hoped that these wise counsels may prevail, and that nothing will happen to stop the stream of visitors which is preparing to start for the gay capital. Birmingham is pretty sure to profit by the occasion; and both at that place and at Paris English electrical engineers will have opportunities for displaying their skill such as occur but very rarely, and of which we trust they will take every possible advantage.

OBITUARY.

WARREN DE LA RUE, D.C.L., F.R.S., PH.D.

It is with much regret that we have to record the death of Mr. Warren de la Rue, which took place on Good Friday. Mr. de la Rue was a native of Guernsey, where he was born in 1815. He was educated in Paris, and for a considerable period was head of the firm of Thomas de la Rue and Co., in succession of his father, until the year 1880, when he in turn was succeeded by his second son, Mr. T. A. de la Rue. In this business Warren de la Rue turned to good account his great scientific knowledge; but the principal work in which he distinguished himself, and on account of which he has attained a world-wide celebrity, is in the application of photography to the recording of celestial phenomena. The following particulars are taken from *"The Electrician" Directory*, and will be of interest to our readers:—"In 1860 he went to Spain with the Himalaya Expedition, and was successful in obtaining a series of photographs of the total eclipse of the sun on July 18. The results formed the subject of the Bakerian Lecture, delivered to the Royal Society in April, 1862. In conjunction with Prof. Balfour Stewart and Mr. B. Lowry he published 'Researches in Solar Physics,' founded on observations made at the Kew Observatory under his directions. He also took an active part in making the preparations for the photographic observation of the transit of Venus in 1874. He established a private observatory at Cranford, Middlesex, but it was dismantled in 1873, and the instruments presented to the University of Oxford, where they have been employed most successfully by Prof. Pritchard in determining, by means of photography, the distance of 61 Cygni and other fixed stars. In 1874 he fitted up a private physical laboratory, where, employing a battery of 15,000 chloride of silver cells, he has, in conjunction with his friend, Dr. Hugo Müller, carried on an elaborate series of researches on the electrical discharge. The results of the researches have been from time to time communicated to the Royal Society and the Académie des Sciences, Paris. 'The Phenomena of the Electric Discharge' was also made the subject of a most interesting lecture, illustrated by a great number of experiments, at the Royal Institution in 1881. Nearly all the results of Dr. de la Rue's scientific work have been embodied in Papers and Memoirs, which will be found in the *Transactions* of the Royal Astronomical, Chemical, and other learned societies. He acted as juror and reporter in the department of Class XXIX. in the Great Exhibition of 1851, was a juror in Class X. of the Paris Exhibition of 1855, and presided over Section B, Class XXVIII., of the Exhibition of 1862. He was a member of the International Electrical Congress, consisting of all the most eminent physicists of all countries assembled in Paris, and of the jury of the Electrical Exhibition held there in 1881. He was also a member of the Consulting Council of the Electrical Exhibition held at the Crystal Palace, Sydenham, in 1882. He has held office in several societies. He acted for some time as honorary secretary

Digitized by Google

of the Royal Astronomical Society, of which he was also president from 1864 to 1866. He was president of the Chemical Society from 1867 to 1869, and again in 1879-88, and was till his death one of its vice-presidents. He was for many years president of the London Institution, from which he retired and became secretary of the Royal Institution in 1878, on the retirement of Mr. Spottiswoode, who was elected president of the Royal Society, but resigned the post in 1882. He was a corresponding mumber of the French Académie des Sciences for the department of astronomy ; also of the Imperial Academy of Sciences, St. Petersburg, the Philomathic Society of Paris, the Royal Society of Upsala, the Society of Agriculture and Commerce, Caen, the Society of Natural Science, Cherbourg, and the Berlin Chemical Society. Three foreign orders have been conferred upon him—Commander of the Legion of Honour, Commander of the Order of St. Maurice and St. Lazare, and Knight of the Order of the Rose, Brazil." Mr. de la Rue died after a short illness from pneumonia. The funeral took place on Tuesday at Kensal-green.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

SECTION III.—MAGNETIC FIELDS OF COILS AND SOLENOIDS.

(*Continued from page 658.*)

The question naturally occurring next is, how many rings are we to consider the cylindrical turn or belt of current divided into? Well, first let us divide it into rings of one centimetre width. Now if the solenoid is l centimetres long there will be l such rings, andthe current (C_1) carried by each will be the total current in the cylindrical belt divided by the length l; that is

$$\frac{Cn}{l} = C_1 \text{ in C.-G.-S. units.}$$

This is usually spoken of as the current per unit length of solenoid. We must carry this subdivision of the rings to a still

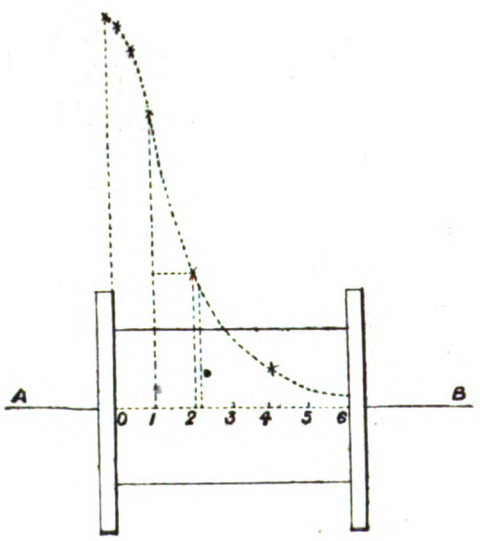

FIG. 148.

greater extent ; but this will be best understood by plotting a curve over the solenoid (Fig. 148) showing the relation between strength of field at the point O produced by different current rings, and the distance of these rings from the point. The axis of the solenoid is along the line A B, and it is at the point O on this axis that we will first set ourselves to determine the strength of field due to the entire solenoid. We might at once take this point at the middle of the coil ; but it is better, as a more preliminary step, to consider the field at one end of the coil first. Any point taken on this axis between the beginning and end of the solenoid will, of course, be the centre of a narrow ring carrying a certain fraction of the current per unit length. It is not necessary to consider now what this fraction may be, for the curve will be of the same shape whatever we take it. In fact, as this fraction of the current would be the same for each narrow ring we take, it may be regarded as constant, and the curve plotted by simply working out the reciprocals of R^3 for a few points on the axis. Raising perpendiculars proportional to the figures so obtained, and joining together the summits of these perpendiculars, we get the outline of the curve as shown. The few points on the axis selected, with corresponding numbers proportional to the field they produce at O, are given below. These few points are quite sufficient to show the general shape of the curve.

Position of ring on axis.	Values of $\frac{1}{R^3}$ proportional to field.
0	·125
$\frac{1}{4}$	·12
$\frac{1}{2}$	·1125
1	·09
2	·0425
4	·011
6	·004

Now, by inspection of the curve it is clear that in any current ring of one centimetre width, that part of it nearer to the point O produces a much stronger field at O than its more remote portion. For instance, in the belt or ring of current between the points 1 and 2 the perpendicular line proportional to the field is much higher at 1 than 2, and if we imagine this ring sub-divided into a very large number of small rings, it is easy to see that the field of each (at the point O) gradually becomes more intense as they are further from 2 and nearer to 1, the increase being in exact proportion to the rise of the curve. In fact, every perpendicular line drawn from the axis between 1 and 2 to meet the curve is proportional to the field produced at O by a narrow ring of current *in the plane of that line ;* and in order to estimate the total field produced by the belt of current between 1 and 2, it is clear that we must add together the values of as many perpendicular lines as can be crowded into that space. But this is the same thing as finding the *area* of the strip included between the two vertical lines at 1 and 2, the curve, and the axis. Now the area of this strip we may consider as made up of two parts—a rectangle and a space like a triangle (shown separated by a dotted line). It would be very easy to find the area of the rectangle, but not so easy to find the area of the triangular space, because one side is curved. But by dividing the space between 1 and 2 into a series of smaller strips the curved side of the triangle in each might be considered straight and the areas found by inspection, adding them together afterwards to get the area of the whole strip. Fortunately we are not obliged to do anything so laborious as that, for by considering any very narrow strip, such as that drawn on the off-side of the figure 2, it will be seen that the little triangle becomes very diminutive, and finally disappears altogether if we take the strip smaller and smaller *without limit*. Just in the same way as the field produced by the belt of current between 1 and 2 is found by measuring the area of the strip contained between these limits, so the total field at the point O due to the whole solenoid is found by calculating the area of the whole curve between the limits O and l. By taking such extremely small strips, then, we may regard them as rectangles of minute breadth, and adding them all together from O to l gives the total area of the curve. It is not necessary to understand the exact process by which this is done so long as the student understands *what* is done and *why* it is done. It will be understood that in adding any series of numbers the process of addition is much simplified if we first separate any factors which are *constant* from those which *vary*. For instance, suppose it is required to sum up all multiples of some number which we will call a, between the limits of $5a$ and $9a$, it is easier to perform the summation by adding the factors which *vary* first ; thus :—$5+6+7+8+9=35$, and then taking the product $35a$, than to add together $5a+6a+7a+8a+9a$. The

Digitized by Google

difference in the labour involved in doing it these two ways is at once apparent by taking a as some fractional number, say $1\frac{1}{7}$. In other words $a = 1\frac{1}{7}$ is *constant* throughout, and it is only necessary to sum the factors which *vary* as above, and then multiply their sum by the constant, giving the final summation of the series, viz., $1\frac{1}{7} \times 35 = 40$. Similarly, in the summation of the little rectangles representing the fields produced by each narrow ring of current there are two factors which go to make up the value of each rectangle, one being constant and the other varying with the position of the current ring. The constant factor in this series is the product $2\pi C_1 r^2$, and the factor which varies comprises the reciprocal of R^3 (which varies with the position of each ring), and a fractional quantity which diminishes the width of the current rings (and therefore of the rectangles) down to an infinitesimally small amount. This latter fraction would be a constant quantity were it not for the fact that it is expressed as a fraction of the distance of each ring from the point where the field is to be determined, and this distance of course is different for every ring. We have now only to take the factors which vary and sum up all their possible values between the limits O and l (the length of the solenoid), the result of this summation being equal to

$$\frac{l}{r^2 R},$$

where R has its greatest value, viz., the distance from the point O to the mean depth of the furthest ring (*see* Fig. 149).

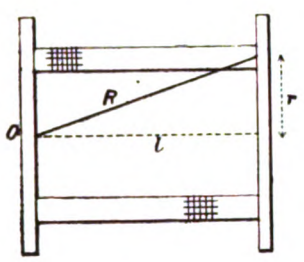

Fig. 149.

The depth of the winding is represented in the figure by the space (partially shaded) between the two bounding lines of the coil, and the line R is from O to a point at the side of the coil central to the winding—in fact, to the point which limits the mean radius r. Multiplying the constant quantity by the sum of the factors which vary, we have the final summation, giving the total field at O due to the entire solenoid, viz. :—

$$2\pi C_1 r^2 \times \frac{l}{r^2 R} \text{ C.-G.-S. units,}$$

which, after cancelling out r^2, becomes

$$2\pi C_1 \times \frac{l}{R} \text{ C.-G.-S. units.}$$

Putting for C_1 its equivalent (Cn divided by l), and cancelling out l, we have for the field at either end of the solenoid

$$\frac{2\pi Cn}{R} \text{ C.-G.-S. units.}$$

(To be continued.)

MAQUAIRE'S "ALPHA" ARC LAMP.

In Maquaire's "Alpha" arc lamp the power necessary for striking the arc and regulating the feed of the carbons is supplied by a small reversing motor. The armature, which is placed vertically between the field magnets, gears by means of a worm on the shaft with a large wheel, the pinion of which drives the upper carbon holder by a rack, so that a revolution of the armature in either direction causes an almost imperceptible motion of the upper carbon in the corresponding direction.

The lower extremity of the armature shaft is pivoted in a movable V-shaped yoke X (Fig. 1), which when the lamp is working is attracted by the field magnets and thus closes the magnetic circuit, at the same time throwing the worm into gear with the wheel. When the lamp is not working the movable yoke is pushed back

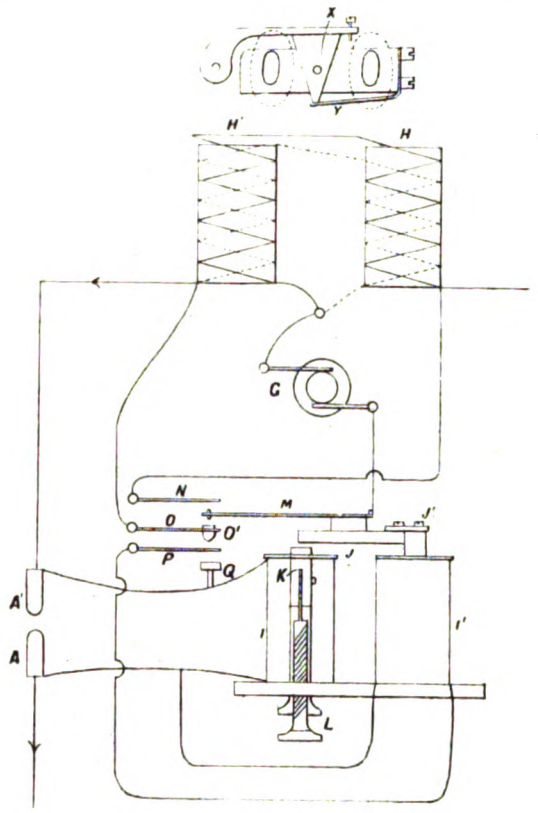

Fig. 1.

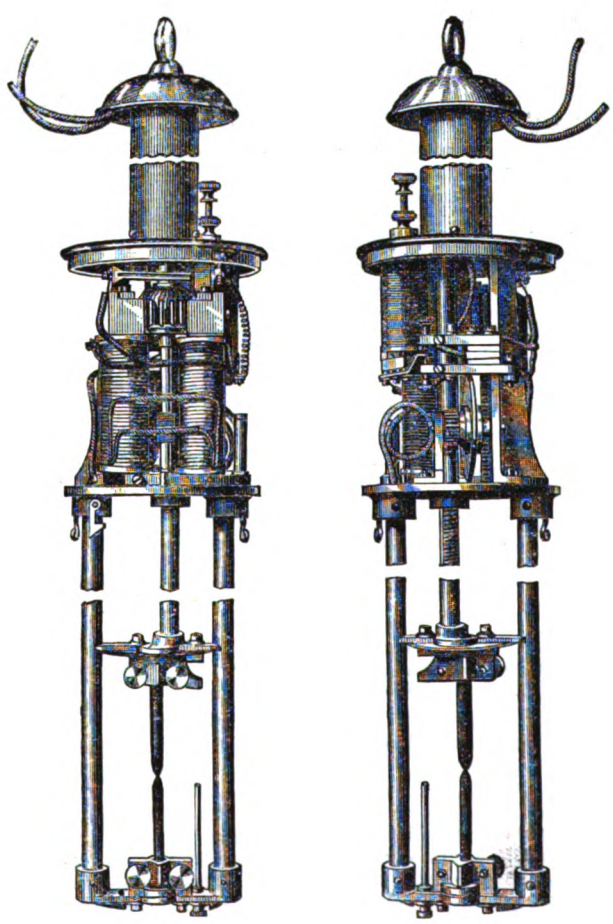

Fig. 2.

Fig. 3.

by a spring Y ; the worm being thus released from the wheel, the rack falls and the carbons A' A come together.

Digitized by Google

The field magnet coils H H′ of the motor are in series with the arc, the armature G being coupled as a shunt on the field coils. The direction and duration of the armature current depends on the position between two contact pieces N O of the movable lever M, one end of which is held by a flat spring, J′, the other end being free to move. A portion, J, of the lever, M, is of iron, and is controlled by an electro-magnet, wound with a coil of high-resistance, I, coupled as a shunt on the arc, having a movable iron core which is adjusted by the screw L.

In the event of the resistance of the arc increasing to too great an extent the shunt coil pulls strongly on the lever M, causing it to press together by means of the insulating stud O′ the contact points P Q, thereby short-circuiting the arc through the coil I′, which increases the pull on the lever and ensures good contact between P and Q.

The lamp may be made to strike any desired length of arc and feed at any potential by altering the position of the contacts N O. The potential on the armature of the motor is 2 volts. As during the time the lamp is in action the carbons can only move under the action of the motor, perfectly steady burning is ensured, more especially as the shunt coil has only to alter the position of the lever, so that any accidental friction in the lamp does not in any way affect the feeding point. Figs. 2 and 3 give front and back views of the lamp.

Lamps of this description have been burning for some time past at Kensington, two in series on the 100-volt incandescent circuit of the Kensington Court Company, and have given every satisfaction.

These lamps, which are also made focussing or double carbon, are constructed by the Planet Electrical Engineering Company (Limited), Victoria-mansions, 28, Victoria-street, Westminster.

ECONOMICS OF PLANNING AND CONSTRUCTING ELECTRIC LIGHT AND POWER STATIONS.*

BY ALEX. P. WRIGHT.

(Concluded from page 625.)

The dynamos required for immediate and intermediate use being decided, probably it would be well to look to the ultimate requirement before settling upon the subdivision of power and the arrangement of engines and shafting. In view of the fact that increases in business will come very quickly, it will be well to bear in mind a scheme for the future arrangement of the station in order that when the time comes for extension, as a matter of addition only, and not a combination of subtraction and addition. The machines which might be used for immediate work and increase, or at all events provision for a portion of the increase, and those which might be suitable for the ultimate capacity, are compared in the following adjacent columns. Circumstances may necessitate the changing of the particular units of capacity, in each case when the immediate location and designing of the building is done, but as a basis upon which to bring about a settled plan a beginning has to be made.

Dynamos—Immediate and Intermediate Use.

Full arc	Two 40-light	= 80 lights.	
Divided arc and	One 20 „ / Four 45 „	= 200	„
Incandescent and (Alternating)	One 650 „ / Two 1,500 „	= 3,650	„
Exciters	Two dynamos.		
Motor	One 80 horse-power generator.		

Dynamos—Ultimate Use.

Full arc and	Two 40-light / Five 50 „	= 330	lights.
Divided arc and	One 20 „ / Eight 45 „	= 380	„
Incandescent and (Alternating)	One 1,500 „ / Two 3,000 „	= 7,500	„
Exciters	Three dynamos.		
Motor	One 80 horse-power generator.		

The capacity of incandescent machines appears to be somewhat lower than the cases A, B and C, which have been assumed as the immediate, intermediate, and ultimate requirements; but experience has shown that not only in electric lighting but in gas lighting, the larger the installation of lamps, as a rule, the greater the proportion not in use at any given time, and this is evidently the case where general lighting is considered. There is not apparently in the above comparision much allowance made for the intermediate increase, but that this will be provided for will be evident when the shafting is laid out. It is proposed to lay out the plant on paper for the ultimate capacity, in order that the building required to accommodate extension may be designed, after which only such of the machinery as may be required for a slight advance on immediate requirement need be provided for, with shafting and power for the increase to such an extent as circumstances may direct.

There are some differences of opinion as to the arrangements for exciting currents. Some believe self-exciting dynamos to be superior, others that individual exciters for each dynamo are better, and others that several exciters, each capable of exciting all the dynamos, are the best. The writer, early in the history of alternate-current installation, adopted the latter plan, for the following reasons:—In the event of the exciting coils only of an armature giving out the armature is rendered useless without a separate exciter; secondly, where, say for instance, two exciters are provided for these alternate-current machines, each doing a portion of the exciting, in the event of an accident to one exciter, by proper arrangement of the switchboard one of the others can be quickly connected to supply the place of the disabled machine in addition to its own work. Thirdly, although objections have been made to this arrangement on the grounds that it is more costly both for first cost and for operation and space, the increase is so slight as compared with the total cost of the plant, and such flexibility and provision for accident is provided, that the small comparative cost may be neglected without incurring the criticism of want of economy. As a rule, in electric light stations practically no provisions are made for relay, even in many cases it being deemed unnecessary to provide spare armatures. The latter precaution is not intended as a slight upon the durability of armatures in general, and while we are not anticipating that they will be repaired except in extraordinary cases, when they are wanted they are wanted very badly, and a regret is felt that such a provision has not been made. Want of relay has cost many a station dearly, not only in actual expenditure but in loss of income and annoyance to customers.

The determination of power for immediate use, bearing in mind the ultimate power required, should be considered after the determination of the dynamo units. Economy in power appears to the writer only to be obtained by the use of such an arrangement of engines as when running alone or combined should correspond with the power required for the dynamo's loads existing at any given time, in order that at all times the engines may be running with loads within the range of their best efficiency. Comparing the requirements called for by the power curve already given with the ultimate requirements, based upon the same experience, we would get comparison of subdivisions of power as follows:—

Time o'clock.	Immediate maximum requirements.	Time o'clock.	Ultimate maximum requirements.
12 to 5 a.m.	125 H.P.	12 to 7 a.m.	450 H.P.
5 to 9	175 H.P.	7 to 3 p.m.	250 H.P.
9 to 3 p.m.	125 H.P.		
3 to 12 night	560 H.P.	3 to 5 night	1,300 H.P.

First making a division between the present and future loads, it is found on comparison that 560 horse-power and 1,300 horse-power are the totals, so that for the moment disregarding the respective variations, and basing only on the maximum loads, a division into 560 horse-power and 700 horse-power for increase would fill the bill—the 600 horse-power for immediate and an additional 700 horse-power (total 1,300 horse-power) for ultimate capacity. Taking up the subdivision of the 600 horse-power, probably the 700 horse-power will not require much subdivision; the variations in the first column of comparisons gives us variations of 125, 175, and 560 horse-power respectively. Divisions of 125 horse-power, 250 horse-power, and 350 horse-power would either singly or combined give a good arrangement for the present, leaving some surplus power (about 165 horse-power), a margin which at times will be more than acceptable. This arrangement, while allowing considerable flexibility, will allow of running with varying loads at an economical point of cut-off. The combinations of such powers would be as follows (in horse-power):—

125	125 + 250 = 375
250	125 + 350 = 475
350	250 + 350 = 600

125 + 250 + 350 = 725.

Comparing these arrangements with the curve it will be evident that at all times the engine would be operating at economical cut-offs if properly handled. Before finally determining this arrangement it will be well to consider their combination with the proposed ultimate increase.

The addition of one unit of 600 horse-power would be suitable, with the ability to maintain the desired flexibility. Continuing the combinations, we would have (in horse-power):—

600	350 + 600 = 950
125 + 600 = 725	125 + 350 + 600 = 1,075
250 + 600 = 850	250 + 350 + 600 = 1,200

125 + 250 + 350 + 600 = 1,325

* From *Modern Light and Heat* (Boston, U.S.).

Digitized by Google

Before the final increase to the plant probably the wisdom of doubling the 125 horse-power units would suggest itself, and it would, therefore, be wise to provide a single engine with foundation, shaft and fly-wheel ready for duplication, even if it were not decided to make the installation in the first instance, with one engine disconnected but ready for connection at a few minutes' notice, if required at any time, to take care of accident. If the idea of compounding were entertained, this might reasonably be done if all the engines could be worked near and at their full capacities. If the first engine was not immediately duplicated the high pressure side of it might be set up with a view to compounding, provided it were decided to use right-angled engines rather than tandem compounds. The use of right-angle engines will have this advantage—that either side may be disconnected at any time for overhauling, and in case of disablement of one section the other runs at high pressure if the piping be properly arranged, as was arranged for by the writer in the new station at Springfield, Mass., thus giving greater relay in the event of accident. The importance of provision against accident cannot be too definitely borne in mind, and particularly the ability to seize the opportunity of small loads for overhauling and inspecting engines. The subject of condensing we think needs no argument, and resolves itself into the use of individual condensers connected with each engine, or independent condensers, the latter being perhaps preferable.

The particular make of engines can be left until after the general plans are made, as will also be the case with the shafting and pulleys, pumps, condensers, heaters, boilers, &c. The successful use of friction clutch couplings and friction clutch pulleys has now been so demonstrated by actual practice, and the advantages to be obtained by their use being so great, there appears to be very little question as to their use in first-class plants. As far as designing the stations with large engines and shafting is concerned, there is now sufficient general data from which the engineer can prepare plans.

If it is decided also to consider the preparation of plans contemplating the use of smaller engines belted direct to the dynamos, the data required, in addition to that included above, will be the probable schedule of engines to be used. Setting down, therefore, the schedule of dynamos already accepted, with the power required for each arranged in a final column, showing, by brackets, the engines required and the machines to which they are to be coupled.

	Dynamos.		Power required by each.		Engines.
Full arc ...	Two	40-light ...	40 horse-power ...	=	80 horse-power.
„	Two	50 „ ...	50 „ ...	=	100 „
„	Three	50 „ ...	50 „ ...	=	150 „
Divided arc..	One	20 „ ...	15 } „ ...	=	75 „
„	Two	45 „ ...	30 }		
„	Two	45 „ ...	30	=	60 „
„	Two	45 „ ...	30	=	60 „
„	Two	45 „ ...	30	=	60 „
Incandescent	One	1,500 „ ...	150	=	150 „
„	One	3,000 „ ...	300	=	300 „
„	One	3,000 „ ...	300	=	300 „
Motor ...	One	80 „ ...	80	=	80 „
Generator ...		—	—		—

Summarising, there will be required :—

Three	60 horse-power engines	= 180	horse-power.
One	75 „	= 75	„
Two	80 „	= 160	„
One	100 „	= 100	„
Two	150 „	= 300	„
Two	300 „	= 600	„
	Total	1,415	

The exciters will be distributed amongst the incandescent engines, and the 650-light incandescent machine could be connected with one of the 65 horse-power engines until change were required. Immediate requirements therefore call for :—

	Dynamos.		Engines.
Full arc.....	Two	40-light.....	80 horse-power
Divided arc	One	20 „ }	75 „
„	Two	45 „ }	
„	Two	45 „	60 „
Incandescent.....	One	650 „	60 „
„	Two	1,500 „ .....Two	150 „
Motor generator		80 „	80 „

Summary.

Two	60 horse-power engines	= 120	horse-power.
One	75 „	= 75	„
Two	80 „	= 160	„
Two	150 „	= 300	„
	Total.....	655	„

There are now two sets of data from which to plan stations for similar purposes, upon which an engineer can prepare general plans, with a view to the choice of a suitable location, in which work he should be left without interference, his plans and estimates being eventually submitted for approval, or as a basis upon which to make such alterations and improvements as circumstances may direct.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

Underground Conduits and Electrical Conductors.*

BY JOHN B. VERITY.

My object in bringing this subject before you this evening is to promote an interchange of opinion and experience concerning one of the few remaining problems connected with the general distribution of electricity in our cities. Since I began to write this Paper, on my return from America, much information has appeared in the electrical press, and the close attention now being paid to the matter in America is equalled by a like spirit of inquiry here. The outcry against overhead wires has been gaining in force, and although the numerous objections urged are devoid of solid grounds, there is a general feeling that any considerable extension of overhead cables for electric lighting is impossible, both on account of the difficulty and no inconsiderable expense in procuring way leaves, and also the attitude taken up by the Board of Trade and others to put a stop to them. Overhead wires in this country may therefore be simply considered as a temporary measure to admit of the Electric Supply Companies getting to work, and permitted only on the distinct pledge of the removal of such wires within a certain distance.

The time allowed for the execution of underground works in Provisional Orders and licenses, although as long a period as could be obtained, is all too short, and a thorough discussion of the subject at the present time, in its numerous aspects, is highly advisable to enable it to be afterwards promptly and adequately dealt with.

In three months we may reasonably conceive that certain Electric Supply Companies will be under legal obligations to at once face the problem of putting high tension electric conductors underground. It will be no petty attempt narrowed down to a small area, but in two special instances the undertaking is proposed to be carried out on a large scale by companies of adequate financial resources and with supply stations already erected or in process of erection.

"Is failure probable?" may seem a singular question to put here, but it is a necessary one leading up to the various difficulties to be encountered, and, in view of the alarmist statements at the recent Electrical Convention in Chicago, one that deserves prominence. Mr. Lynch's Paper giving the results of the working of underground cables, and which was practically the only part of the meeting reported in the English papers, showed but one side of the case, and from the discussion following it (and which appeared in the *Electrical World*, March 2) much was to be learned. Many of the companies operating underground cables had from some cause or other not given their opinions, and the failures alluded to were in several instances traced to defective conduits, insufficiency of insulation, poor insulation, imperfect jointing and cheap work. Cheap work has damned electrical enterprise before now, and it behoves us all to guard against a recurrence of it. Anything also on the subject of conduits and underground electric conductors emanating from American electricians has to be carefully sifted, as not even are our Unionists and Home Rulers more defined than certain "overhead" and "underground" men in America. The overhead men accuse all the underground men of being interested in some of the dozen forms of conduits put forth, the underground men retaliate by saying, "You don't want to go underground," and "You boldly say we cannot go underground."

In England we stand on a different footing altogether; if much more electric lighting work is to be done we must go underground, and having recognised that, how can it best be done? The necessity and best form of conduits are the first points for discussion.

The successful working of a system of underground electrical cables in a city must be linked to an arrangement of ducts, as the impossibility without such of getting at the cables for repairs, inspection, tapping and alterations is evident. Even if the local authorities remained quiescent during any continual disturbance of our streets on account of electrical conductors, commercial interest must prevent such occurring. The expense of opening up a crowded thoroughfare to lay underground cables is in many cases as great as the cost of whatever is being laid, while by using a duct this expense once incurred should not be again necessary. Again, if the cable be laid in the ground without a duct, it is necessary to armour it and lay it down at first equal to all possible requirements, otherwise any extension of the lighting beyond the capacity of the cable would necessitate a repetition of the whole original work. In this case the first cost of such a large cable would be nearly as great

* Paper read before the Institution of Electrical Engineers, April 11, 1889.

Digitized by Google

as the smaller cable and duct together. Finally, the life of the best cable for high-tension currents cannot at the present be predicted, and this, together with the other reasons, undoubtedly prove that a conduit with a drawing in and out system is eminently desirable.

An ideal system for underground work is a brick subway, well drained and ventilated, and of sufficient size to permit of a man working in it; failing this Utopian arrangement, what comes next best? In New York, where the matter has been placed in the hands of a Board of Electrical Control, they start out by saying that a conduit or subway for electrical conductors is nothing more than a mechanical protection for the wires within it and a convenience for placing or putting them underground. In their experience of three years the Board of Electrical Control have naturally tried and abandoned many conduits. In a room of the Telephone Building, New York, occupied by the Subway Construction Corporation, there is a heap of experience—experience gained at no little cost—that it would be of advantage for engineers who lightly propose undertaking such work to see and meditate on. Wooden conduits, bitumen conduits, asphalte conduits, earthenware conduits, samples of underground conductors—all are here in what is termed the museum, and afford a collection of failures most instructive as to *what not to do*.

In many instances, however, the conditions there would not apply to England. At present we have no system of steam heating with leaky pipes, causing trouble wherever they go. Again, here we have not those great extremes of heat and cold, the frost compelling conduits to be laid at an average depth of four feet and the heat causing various troubles with asphalte and bitumen conduits.

At the same time, from the numbers of miles of conduits laid down there should be something to learn, and I therefore propose instancing some of the more important conduits known in America and elsewhere.

Conduits are divided into two classes—the so-called solid conduit and the hollow conduit. Solid conduits are useless considering here, as they practically consist of cables bedded in asphalte or bitumen, which means ripping up the ground and breaking the enclosing mass if alterations are required. With hollow conduits, the difficulties to be encountered seem to be to provide a smooth channel, with convenience for drawing in and out to prevent explosions through accumulation of gas, and to keep them reasonably dry and water-tight.

In the discussion at Chicago it was stated that in one instance it was necessary to keep a blower going to ventilate an iron conduit, while several authorities appear to consider it advisable on dry days to take off the manhole covers. Accidents have, of course, occurred from conduit explosions, and the engineer of the United States Electric Lighting Company instances one where the manhole covers of the conduit were blown over the roof of a four-storeyed building. But in England, again, the work done by the Gas Companies is far better, and the leakage in our streets is not in any way to be compared with the quantity of illuminating gas which wanders, fancy free, through the soil of many of the cities of the States.

It appears desirable that conduits should be ventilated, and the form adopted, where possible, is to ventilate them by means of a pipe running into the base or up the interior of the street lamp-posts. With regard to keeping them water-tight, this is another constructional question surely capable of being properly dealt with.

Many of the complaints of leaky conduits and ultimate failure of cables I trace back to the Dorsett conduit.

This, one of the earliest forms of conduits, is built of blocks formed of a combination of coal-tar pitch and fine gravel, cast with tubular openings 2½in. in diameter running through them from end to end. They are jointed by pouring soft mastic into the cracks between them, and the blocks made to adhere to this by warming their ends with hot irons and allowing them to cool, after being well set. To prevent the melted mastic from closing the ends of the passages, tubular pieces of paper are inserted, making a sort of internal sleeve coupling. The conduit so formed terminates in brick manholes at the street crossings. The objections to this conduit are that it is brittle, porous, inelastic, and cracks with changes of temperature, so that it is not likely to be made water-tight with average workmanship.

Creosoted wood conduits have been extensively used in the States, and have been a leading cause of trouble and failure with lead covered cables. A chemical action takes place between the crude creosote and the wood, setting free acetic acid and carbonic acid gas, which, reacting on the lead pipe, converts its surface into a film of acetate of lead, the action continuing until the entire sheathing is converted into carbonate of lead or white lead. Creosote is also said to rot rubber. There are, of course, ways of overcoming such troubles, but as I do not think we shall be disposed to use creosoted wood conduits in this country, the matter need not be given much prominence here.

The difficulty of obtaining a conduit that shall be anything more than a mechanical protection for the cables is certain to be great, as however good the insulating material forming the conduit may be, and however water-tight the joints, there is a difficulty in excluding dampness unless it is practically air-tight, as damp air enters the conduit and condenses on it.

Several conduits have been made, however, with a view to afford electrical as well as mechanical protection to the cables. The Callender bitumen conduit, for instance, is well known here. It is

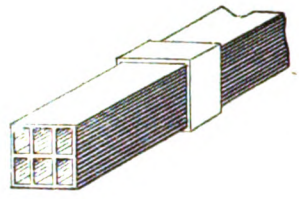

Fig. 1.—The Lake Conduit.

being extensively laid down by the Chelsea Electric Lighting Company, and five hundred yards of it is being tried by the Metropolitan Electric Supply Company. For high-tension currents its use

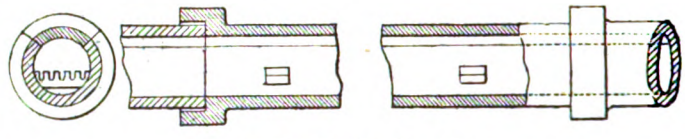

Fig. 2.—The Doulton Conduit.

is doubtful, but perhaps in the discussion something may be said on this point.

Vitrified 3in. sewer pipes laid in concrete with cement joints have been used in some instances for underground work.

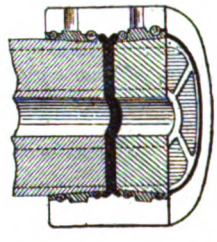

Fig. 3.—The Hurlbut Conduit.

The Lake conduit shown in Fig. 1 is made from the best stoneware clay vitrified and well glazed. This conduit, said to be used with success by the United States Electric Lighting Company at Washington, is constructed with six compartments, each being

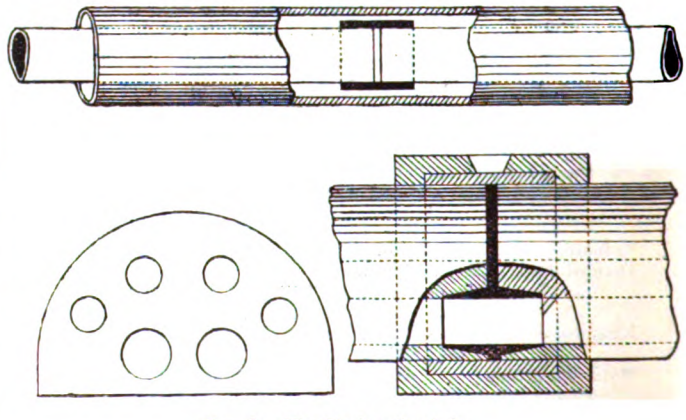

Fig. 4.—The Verity Conduit.

2½in. by 4½in. It is delivered in short lengths, and the joints are protected by stoneware covers set in cement.

The Doulton conduit (Fig. 2) consists of a glazed earthenware pipe, in which the cables are laid separated by toothed insulating partitions. A space at the bottom drains off the condensed moisture, which is got rid of by suitable traps. The joints are made like ordinary drain pipes.

Digitized by Google

A serious objection to such conduits seem to be the joints which are made with cement. It is very difficult to break a cement joint without also breaking the pipe, and as it might be necessary at times to put in a new length, this could not well be done. Again, the rigidity of a cement joint is a disadvantage, as in laying earthenware pipes it becomes necessary at times to alter the alignment.

The Hurlbut Conduit System (Fig. 3) was designed to overcome this difficulty by means of a flexible joint. The joint is shown in the diagram. C represents asbestos gaskets recessed into the coupling and resting against the pipe. B is a cavity formed between the asbestos gaskets and is filled with a permanently plastic sealing material. A represents openings through which the sealing material is poured. It is claimed that such joints will always remain both flexible and hermetically sealed.

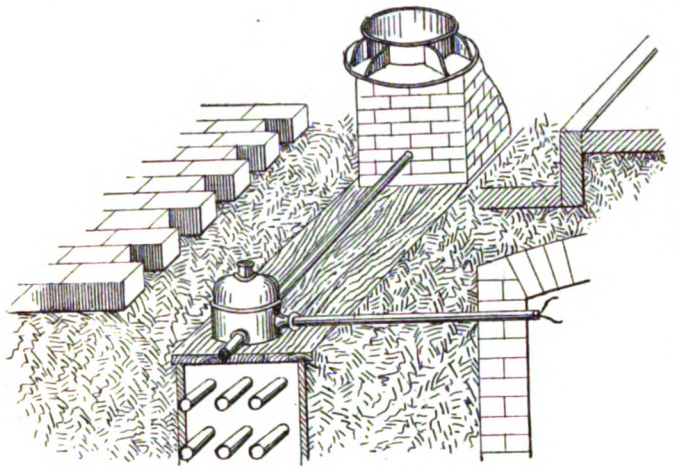

FIG. 5.

Mr. B. Verity's Conduit (Fig. 4). This is a system of glazed stoneware clay conduit with separate channel for each conductor; the joints are made as shown on diagram, the double cone piece being inserted before the jointing material is run in. The special object of this conduit is to enable bare conductors to be used insulated only at the manholes or where they are likely to be handled. Experiments have proved this form to be capable of standing almost anything mechanically when laid on a fairly good bottom. Mr. Verity has also patented a system of glass tubes in iron pipes for the same purpose.

Pipes of glazed earthenware with several ducts form a good mechanical protection, being capable of resisting considerable crushing pressure, while the glazing both inside and outside provides also, under certain conditions, a first-class electrical protection. If it be desirable that the conduit should be formed of a non-conductor, then nothing could be better than such glazed earthenware, which also is of no great cost. The difficulty of maintaining good joints with earthenware pipes has been referred to some time ago in connection with conduits for telegraph purposes, several instances having been given by Mr. Preece and others of roots of trees, branches, and other vegetation having made their way through the joints. Is this capable of being overcome by a flexible joint, which should at any rate prevent joints giving through expansion and contraction?

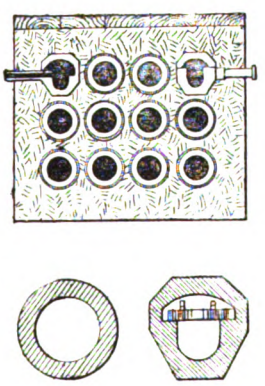

FIG. 6.

The great disadvantage, however, to the use of earthenware pipes in many places in a city like London is the amount of space required for them; in fact, the difficulty of laying any conduit at all in some of our streets will be found simply enormous.

As a mechanical protection only, it is immaterial whether the conduit be a non-conductor or not. The simplest form of such a duct is, of course, an iron pipe, and the Western Union Telegraph Company among others have laid cast-iron pipes of 4in. and 5in. diameter with manholes at a distance of about 450ft. apart. In the majority of cases, however, the plan has been to lay a number of separate iron pipes in a concrete bed, by which arrangement the pipes can be crowded, or curved, or kept apart, as may best overcome any difficulties or obstacles met with underground. For instance, four pipes may be laid on the same level in two layers, or where only a narrow excavation can be made, the pipes can be curved round so that two pipes are abreast in four layers. In this way the trenching is often materially diminished. Screw-jointed, asphalted, wrought-iron pipes of two or three inches diameter laid in hydraulic cement concrete are said to present the greatest tightness of duct against gas and water, together with the greatest strength. (See Figs. 5 and 6.)

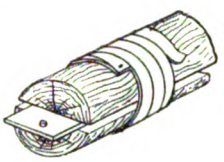

FIG. 7.—The Chenoweth Conduit Core.

Cement lined sheet-iron pipes, however, possess some advantages, such, for instance, as smooth interiors and the advantage of an iron enclosure without the cable being brought into contact with it, and on the sheet iron being eaten away the cement still retains the pipe form. Zinc tubes again have been used, but are liable to be dented in, and asphalted concrete is often preferred to hydraulic cement concrete.

Whatever system of pipes be used, it is important that they should have smooth interiors and close joints, and every conduit of whatever kind must be thoroughly well bedded, so as not to be liable to displacement from above.

An ingenious conduit core (Fig. 7) has been devised by Mr. Chenoweth: a wooden cylindrical rod, 14 or 20 feet in length, is cut in two, forming two half-cylinders, and the space removed is occupied by an iron rod having a thickness equal to the portion sawed out. This forms the mandrill or core shown in the illustration; a ribbon of galvanised iron 1in. wide and a thickness of No. 27 gauge is wound spirally round this from end to end, securing the ends to the wood to prevent unwinding.

After painting the outside of the core with a mixture of clay, soapstone and water, the core is placed in the ditch on crossed pieces of wood. If more than one duct is to be constructed, other cores are placed side by side, concrete is then well tamped round, bringing the top to an even level. The iron rod is then removed, as well as the two pieces of wood and the fastenings of the ribbon ends. When the cement hardens, the iron spiral can be drawn out at any manhole or unfinished portion of the work. It is claimed that the surface coating of clay and soapstone adheres to the interior of the duct and produces a smooth surface, while a monolithic structure is ensured water-tight by reason of its construction. I think this is another instance of American ingenuity.

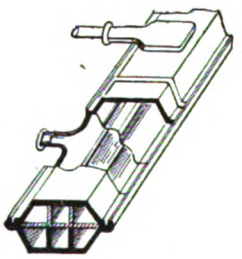

FIG. 8.—The Johnson Iron Conduit.

The Johnson Iron Conduit shown in the illustration (Fig. 8) is said to be very successful, and I saw portions of it as designed to be laid in New York City. It is made in sections about 6ft. long and has six ducts; the three lower ones and the central duct on the top could be used for mains, and the two outer top ducts for

Digitized by Google

house-to-house and street lighting. Where any house circuit is required, the top half of a single section is taken and a new half-section with a hole in it, to which an elbow can be bolted, is fixed in its place.

A form of conduit made by Mr. W. E. Irish, of Cleveland (Fig. 9) is also worthy of notice. In the illustration the conduit consists of a tubular pipe cast in sections, with flanges which are recessed on the inside to receive a rubber ring forming a gasket between the two sections when bolted together. The conduit is provided with a longitudinal slot, or opening along the top, with inwardly inclined sides and flat surfaces on either side of the slot, to which the cover is secured by screws. To prevent the entrance of moisture through this slot, a strip of rubber or leather is first laid on the top of the flanges extended from one outer edge to the other. On this a solid wedged-shaped piece, which fits into the slot snugly, is placed so that on the cover being screwed down the wedge with the packing surrounding it is forced into the slot so as to seal it perfectly. It is claimed that there is great convenience in laying wires with this conduit, and that any wire can be tapped at any point by simply removing the cover and making the necessary connections. The illustration represents the conduit with a branch, also a junction box, &c.

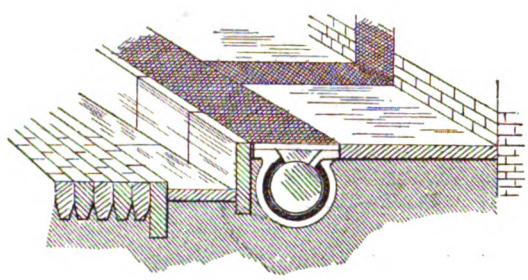

Fig. 9.—The Irish Conduit.

Figure 10 represents Mr. J. E. H. Gordon's system as used by the Metropolitan Electric Supply Company; the cables are drawn into an iron pipe and smaller iron pipes are led from the house junction boxes to carry the wires for house lighting. Testing boxes of a larger size and built of brick are provided at intervals.

It is generally admitted that an important point in underground work is good manholes. Mr. W. D. Sargent, in a paper read before the National Telephone Association, 1888, said that within reasonable limits it is almost impossible to get these manholes or working chambers too large, and that they have been compelled in many instances to rebuild and enlarge the manholes at first designed.

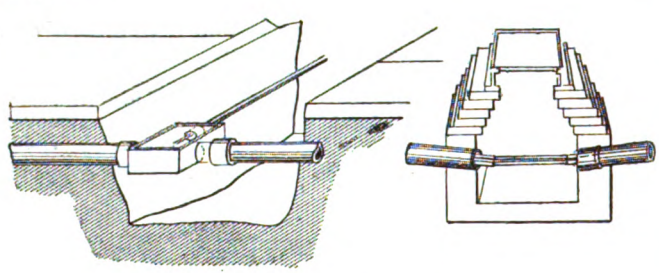

Fig. 10.—The Gordon Conduit.

There is no doubt they must be of good size for convenience of drawing in and out, which is often a difficult matter, especially with lead-covered cables. In one instance, in Chicago, the manholes are built in octagon shape, in brick and cement, about 4ft. by 4ft., being made air-tight with screw head and rubber gasket, and testing boxes placed in them, so that troubles can be readily located, faulty wires drawn out, and good ones put in. In other cases the manholes vary from 3ft. 6in. to 6ft. deep with iron curbs and tops and cement bottoms, and the covers made practically tight against water, many of the lids draining the water from the edge and collecting it in the centre, thus diminishing the liability to leakage at the gasket. With the Johnstone and the Irish conduits, it is not necessary to provide for house connections, as the alteration can be made at any time afterwards when an application for light is received. But, as a rule, hand distributing boxes, made of cast iron with screw-head and rubber gasket, are fixed one between every two houses, and after jointing the boxes are often filled with bituminous or insulating compound. In the cement-lined pipe conduit system one pipe is occasionally placed at the top for the house distribution and connections made with the mains at the manholes. As to the frequency of these latter, much depends on the alignment of the conduit; at angles or changes of grade small manholes are necessary.

The combination kerb and gutter conduit (Fig. 11) shown in the illustration, is worth notice. The kerb and gutter is made of fine concrete, one part of Portland cement, ten parts clean sharp sand, and three parts of broken stone, and the exposed surfaces coated with a granilitic mixture, 1½in. thick, such as is now used for some of our London pavements. A conduit for electrical conductors of any reasonable size can be formed as shown in the inner angle of the kerb with handholes from above closed with iron covers at intervals. The illustration is taken from the admirable report on underground wires by Major Raymond, the engineer, Commissioner for the district of Columbia, and which contains valuable information on many points.

It has been snggested some time ago that the kerb stones should be removed from busy thoroughfares and replaced with a hollow kerb edged with cast steel, and the suggestion may bear fruit in the future.

As I still have to deal with electrical conductors I cannot here refer to the general cost of laying conduits as at one time I proposed

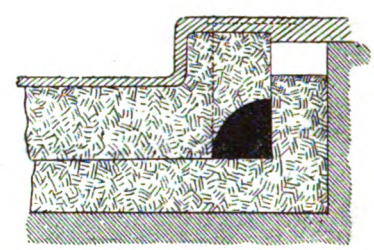

Fig. 11.—Combination Kerb and Gutter Conduit,

doing. The principal cost, however, of laying them is in making good, and this depends on the material of the road, the cheapest being macadam, varying from 5s. per square yard, whereas asphalte would be nearer 20s. per square yard.

The difficulty of laying any form of conduit in some of our London streets must, as I have already said, be very great. The last comer will of course feel this the most, and although the Hydraulic Engineering Company may have recently had much trouble to find room for their pipes, the Electric Supply Companies again will have an easier task than the Telephone Company, who are putting off the evil day.

As to what form of conduit is most suitable for London and our provincial cities there will be differences of opinion, but I trust the discussion following will narrow it down to a small issue upon which such work can be undertaken with a tolerable surety of its lasting success.

(To be continued.)

SOME ELECTRIC LIGHTING CENTRAL STATIONS IN EUROPE, AND THEIR LESSONS.—Part I.*

BY PROF. GEORGE FORBES.

(Concluded from page 681.)

Rome.

The station at Rome, started by the gas company in that city, is the finest example of an alternating-current central station which I have yet seen. But it has been very costly to establish. Many of the details contain hints of the greatest use to those who are at work on this subject. The whole plant has been contracted for by Messrs. Ganz, of Buda-Pesth.

There are two self-exciting alternators of 150 horse-power each and two independently excited ones of 600 horse-power each. These give 42 amperes and 160 amperes respectively, and 2,000 volts. At present 9,000 glow lamps of 16-candle power are supplied and over 200 arc lamps. All the machines are capable of working in parallel, even the large and small ones together. The number of alternations is 5,000 per minute, or 2,500 complete periods. The greatest distance to which current is at present supplied is 4½ kilometres, or about three miles. The feeders all go to the Piazza Venezia, and then branch off into three mains in different directions. The loss in the secondary circuits due to loss in the feeders

at present is only 0·6 volt at the maximum and that due to the mains is the same, the length of feeders being 1,600 metres.

Siemens concentric conductors are used throughout. The feeders are each 220 square millimetres section, or 0·35 inch. Drawings of the junction boxes by Siemens and Halske are shown in Fig. 2, indicating the means of attachment by clamps of the two ends of the inner and outer concentric wires. The cables are laid in a wooden box which is then filled with cement. Seventeen kilometres of cable have been laid up to January, 1888. The feeders have been working since September, 1887. The transformers are all of 10 horse-power, with about four amperes in the primary and 75 in the secondary. 110 volts are used in the secondary, but the secondary coil has three terminals, one half-way along the length of wire. This is to enable a three-wire system to be used for the secondaries when arc lamps are used, consuming with their resistances 55 volts each.

The old type of converter with iron wire wound round the copper coils has been abolished. The iron part is built up of circular flat ring-shaped discs of iron. These are firmly clamped together by iron clamps which form the support of the instrument. The copper coils are wound upon the segments of the rings between the clamps. The primary coil is underneath the secondary. The converter has an iron circular disc at top and bottom fixed to the clamps, and this enables the instrument to be easily rolled about without injury, which facilitates handling. On the top is a porcelain disc on which are placed the terminals and fusible cut-outs. These are short strips of thin metal held in pasteboard, and can be slipped in and out with the greatest ease. Drawings of these converters are shown in Figs. 3 and 4.

The small machines are intended to work 1,000 lamps of 60 watts. There are twenty poles, and 250 revolutions per minute. A derivation is taken from a commutator to excite the machine. Sulzer engines are used for these dynamos, acting direct on the dynamos. The steam pressure is 120lb.

The automatic resistance for regulating the exciting current, invented by M. Bláthy, is very effective. The exciting current passes through a solenoid actuating an iron rod which is supported at one end of a balanced lever. The bar is weighted with a float in water, and water can be put into the float. On the top of the iron bar is a cup of mercury which, in falling, breaks contact with the ends of wires dipping down into the mercury cup. These ends are at different depths, so that the wires are cut out of circuit in succession. The wires go to resistances. This automatic adjustment acts well over a considerable range.

The exciters for the large dynamos are driven by Westinghouse engines. They are governed by hand for the large changes, and then the automatic regulation comes in. Such a method of regulation is necessary with machines having so large an amount of self-induction. This is the only satisfactory regulation of the kind which I have seen at work. It is one of the small details on which the success of a station depends, but which are often forgotten by the inexperienced until the want is felt.

The two large machines have forty poles each on the revolving field-magnets. Both field-magnets and armature are divided into two series in parallel. When the machine is illuminated by an arc light, to which it supplies the current, a curious optical effect is produced. The arc being periodically made and broken, the revolving magnet-poles are seen fixed in position, and the amount of lag with different loads can be seen directly. The efficiency of these machines is said to be 90 per cent., including the exciting current. These machines are so constructed that the cover which contains the armature coils can be drawn away, by means of a handle, shown in the photographs exhibited, over the electro-magnet ring, without the necessity of using any hoisting tackle or other machinery. Moreover, the construction of the fixed armature is such that any single coil can be removed in a few minutes or exchanged. The iron of a section of the armature is in this case removed with the coil. The iron plates of which these armature sections are made are T-shaped, so that the centre of the coil is filled with iron. In the smaller machines there is not nearly so much iron in the coils. In the 600 horse-power machines the energy absorbed in exciting at full load is said to be 3½ per cent. of the full load.

The T-shaped iron plates of the armature (K^1) (Fig. 5) are pressed together by strong bronze press plates (S^1, S^2) and a screw (C'). The wire bobbin is then slid on and held by screws. These segments are fastened to two traversers (T) by the screws (R), which traversers are in turn screwed with an insulating layer (U) to the side-plates of the framework of the machine.

The field-magnet wheel is constructed as follows:—U-shaped soft iron sheets (K), are so arranged together as to form a star, to which is added a similar star, with an insulating layer between, placed in such a way that the interstices between the sheets composing the lower star are covered by the sheets of the upper star. In this way many iron laminæ are put one upon the other until there are sufficient to form the whole electro-magnet wheel. The pile so formed is then pressed together to form a compact whole by means of two stiff discs (S), two bosses (N), and the screws C. The bobbins M are slipped on to the core (K), and held down by means of the bobbin-holder (H) and screws (C_1). The subdivision of the iron in the field magnets is necessitated by the teeth of iron in the armature projecting inwards through the coils.

The large engines are by Ganz and Co. They are carefully balanced and are provided with starting gear.

A drawing is exhibited of the switch-board (Fig. 6), which is very ingenious but very expensive. The board is about 8ft. high and 17ft. long. It is divided into four sections, one for each dynamo, and each section is divided into six, one for each pair of feeders. A pair of 4-foot horizontal bars runs along each dynamo section, connected with the two poles of the dynamo. Two vertical bars descend from these at each of the six parts allotted to the six circuits. Six pairs of horizontal bars are connected to the six pairs of feeders (only three are as yet in use), these pairs being one over the other. At each feeder section a pair of vertical copper bars descend from the horizontal feeder bars corresponding to that section. Thus we have at each feeder section two vertical dynamo bars and two vertical feeder bars, the lower ends all being at the same level. Mercury cups can be raised to connect each dynamo bar with a feeder bar, or lowered to disconnect them. The chief object of the switch-board is to enable us to switch any number of dynamos in or out of connection with any feeders simultaneously and instantaneously. I will now describe this action, referring to the diagram. In the normal condition the crank (A) and handle (B) would be as shown in the side elevation, one crank to each mercury cup (C). If it be required to put on to the dynamo the feeder No. 6 and take off No. 1 from the dynamo represented by this part of the switch-board, the handles (B), with cranks (A), corresponding to these feeders are pushed bodily to the left; the web of each crank is thus made to fit in a vertical slot in the disc (E), which disc is connected to the bevel wheel (G) by a hollow spindle to which (G) is keyed, this bevel wheel gearing with the bevel wheel H keyed on to the shaft (I), running the whole length of the switch-board. The crank of No. 6 would be diametrically opposite that at No. 1, since one was disconnected and the other connected to a circuit. The lever (L) is then thrown over against the other stop, causing the crank No. 6 to be raised from its lowest to its highest position, and that of No. 1 to be correspondingly lowered.

The voltmeters in this station by which the pressure at the lamps is kept constant are regulated by means of two circuits, one being a shunt on the dynamo terminals and the other carrying the main current. These are passed through converters, and the secondary currents actuate a solenoid in opposite directions. This compound-wound voltmeter indicates the pressure at the lamps, and is maintained constant. Prof. Mengarini has devised an ingenious recording voltmeter for marking in a daily curve the pressure at the dynamo terminals at each minute of time. These show variations of 5 volts at different hours.

There are fifty converters now at work, each of 10 horse-power. The efficiency of these converters is 95 per cent. at full load. That of Messrs. Ganz's 5 horse-power converters is 92 per cent., and the 2½ horse-power is 88 per cent. This is far higher than with many of those now made in England. The House of Parliament is lighted by four banks of five converters each.

A METHOD OF DETECTING DISSOLVED CHEMICAL COMPOUNDS AND THEIR COMBINING PROPORTIONS.*

BY G. GORE, LL.D., F.R.S.

The method is based upon the general truth that "when substances chemically combine they lose some of their power of exciting a voltaic couple, and the amount of this power can be measured by means of the "voltaic balance" (see Roy. Soc. *Proc.*, Vol. XLIV., p.p. 151-294). It is briefly as follows:—Oppose and balance the current from a small voltaic couple of platinum and unamalgamated zinc in a known quantity of distilled water through a suitable galvanometer by that from a perfectly similar couple. Dissolve in separate, equal, and known quantities of distilled water a series of mixtures of the two constituents A and B of the supposed compound, in the proportions of their atomic or molecular weights, and multiples of them, some having an excess of A and others of B. For instance, if both are monads, mix them in the several molecular weight proportions of 5 A+4 B, -4 A+4 B, -and 4 A+5 B, but if A is a monad and B a dyad, then use 3 A+2 B, -4 A+2 B, -and 5 A+2 B. Add sufficiently small quantities in succession of one of these solutions to the water of one of

* Abstract of a Paper read before the Royal Society, January 17th 1889.

Digitized by Google

the voltaic couples until the needles of the galvanometer commence to move, and note the proportion added. Recharge the cell with distilled water, clean the metals, red-heat the platinum to expel absorbed hydrogen, and repeat the experiment with another of the solutions, and so on until the mixture has been found of which the largest proportion is required to move the needles—that is the one which has the smallest energy, and which has its constituents united together chemically in definite proportions by weight.

By means of suitable examples the author has shown that the dissolved substances unite together in the definite proportions by weight of their ordinary chemical equivalents. He has also experimentally examined the question of the limit of complexity of chemical combination of substances whilst in solution together in water, and although a definite compound was formed having the formula K^2SO^4, $16KNO^3$, $4A_mCl$, $2N_aCl$, 8KCl, 32LCl, the limit of complexity of combination did not appear to be nearly reached.

He states that he has examined by the above method more than 180 different mixtures of dissolved substances, but has not found one in which definite chemical union is not more or less clearly indicated by a minimum amount of voltaic energy, coinciding with the proportions of the ordinary chemical equivalents of the substances. The mixtures included a great variety of soluble salts, acids, and elementary substances and their compounds. And he concludes that *every electrolytic substance, when dissolved in water, unites chemically in definite proportions by weight with every other such dissolved body*, provided no separation of substance occurs, and that they unite to form compounds of apparently unlimited complexity.

The voltaic balance method may be employed to ascertain the degrees of valency of substances, the basicity of acids, the purity of soluble bodies; to examine the internal constitution of electrolytes, the distribution of acids and bases when together in solution; to measure the rate of chemical change in aqueous solution; to examine the chemical constitution of dissolved isomeric mixtures, &c. As an illustration of the latter two instances are given in which two mixtures possessing the same ultimate chemical composition exert very different amounts of voltaic energy.

The author states that it would be easy to indicate a very large number of mixtures which might be examined by this method, and thus lead to the discovery of probably thousands of definite compounds which exist only whilst in solution, and are decomposed on evaporating or crystallising the solutions.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 13, 1889.

The importance of dealing decisively with the question of the leakage from the gas mains here does not diminish as the subject is looked into, and it is beginning to dawn upon some of the officials interested that they have a pretty big problem to deal with. In my last letter I mentioned the recent explosions of gas in the electrical subways in this city, and stated that they had caused no little sensation. Since that time the investigation which was begun by the Board of Electrical Control has been pursued, and it develops daily new facts of interest. It appears that there are no fewer than 1,080 miles of gas mains on Manhattan Island, which have been laid down at various times, and some of which are 30 or 40 years old. From every mile of these mains more or less gas is escaping. So long as the lost gas is absorbed in the streets and in the soil under the bedway of the roads it does not do much harm, and but little notice is taken of it; when, however, the streets are turned up for any purpose, the offensive nature of the soil saturated with gas over every inch of it becomes apparent, and when it comes to the question of constructing the subways the main difficulty is found to be getting rid of the gas which, accumulating in the ducts, renders it impossible to enter the manhole until it has been pumped out by hand. The gas, moreover, is not only the cause of explosions, but is a bitter enemy of the cables which have gone through the ducts, attacking their insulation, and no matter how good and perfect they may be, seriously affecting their usefulness after a time. This week, closely following on the explosion which ruptured the subway at Twenty-third-street and Fifth-avenue, and probably rendered it more liable than ever to the accumulation of gas, a test has been made of a new cable which has been drawn in for the United States Company. This cable is now carrying 10 arc lamps, and instead of erecting new poles for them the old street gas lamps have been utilised. The test is spoken of as having proved successful in every respect, and in consequence there is great jubilation among the newspapers and the subway people. I need hardly point out that this rejoicing is a little hasty, especially in view of the fact that arc light circuits that have been tried underground before have been more or less expensive failures. However, the results six months or a year hence will show what the actual value of the test is. I may note in passing that the use of the old gas lamp posts instead of the lofty poles hitherto used for the electric light is regarded as an improvement, chiefly by the storekeepers in the vicinity, as the low lights give better illumination for their show windows and interiors.

The early coming of spring has given another fillip to the activity already existing in the electric railway field, and one hears of new projects and new roads in every direction. The Sprague, Thomson-Houston, Bentley-Knight, Daft and other companies report themselves as overcrowded with work. I heard this week that the Thomson-Houston Company were something like 250 car trucks behind their orders, and saw little prospect of catching up without an increase of their force. The popular approval of the electric railway is shown by a series of noteworthy testimonials published by the Sprague Company from the mayors of various cities in which their system is in operation. In fact, in these cities it begins to be hard to find a man who is willing to say a word against the electric railway. Among the improvements recently adopted that have added to the efficiency of operation are the carbon brushes used by the Thomson-Houston Company; and now we seem to be near the day of the motor which, like some human beings, will run better when it is wet than when it is dry. Your readers will probably recollect that in his Paper read before the American Institute of Electrical Engineers, Mr. Frank J. Sprague spoke of introducing a motor that can be washed down with a hose, and so clear all the dirt that would accumulate in a long day's run under the cars. His remarks seem to have inspired the Thomson-Houston Company, for Mr. Merle J. Wighteman this week describes some remarkable experiments made at the Lynn factory with a Thomson motor. One of the company's ordinary motors, he says, is fitted with a new waterproof armature of most recent design which, while running with a difference of potential of 500 volts at the brushes, was doused with successive pails of water. Armature, commutator, brush holders, field and connection terminals, received each a pail or two, and the motor ran as quietly under such treatment as though it were an Englishman taking his accustomed cold bath in the morning.

Prof. Elihu Thomson, who has already enriched the field of electricity by so many admirable inventions, has added to his laurels by a recent description of an apparatus, or rather by the enunciation of a new method of regulating transformers, which cannot fail to have considerable influence on the employment of this form of apparatus. Prof. Thomson's latest invention consists in so constructing the transformer that the primary may be connected to an alternating source of potential and the secondary may be made to deliver either constant current or constant potential as desired. The principle upon which the transformer is constructed is analogous to some extent to that in the method of regulation employed in the Trotter dynamo, in which a magnetic shunt around the poles of the field magnets causes the variation in the field strength, which regulates the current delivered. Prof. Thomson uses this principle in a beautiful manner, and the apparatus itself is extremely simple. The ordinary converter is merely provided with two tongues made integral with the sheets of iron, and these tongues approach each other more or less closely according to the amount or quality of regulation required. Thus it will be evident that with these two tongues part of the lines of force generated will pass through the air space between them and part through the section of iron encircled by the secondary coil. It will thus be seen that any tendency to increase in the current flowing in the primary coil, resulting from a lowering of the resistance in the circuit of the

Digitized by Google

secondary, will be at once followed by the development of increased magnetisation of that part of the core enclosed by the primary coil by the formation of increased magnetic lines across the air space; while at the same time the self-induction of the secondary coil itself will undergo an increase, owing to the fact that a path of variable pressure for the maximum in the coil is likewise formed across the air space. In addition, the partially closed air path has an added effect due to the repulsion of the inducing magnetism in the secondary. This form of regulation is particularly adapted to the maintenance of constant current in the secondaries of transformers connected to constant potential circuits, and hence permits of arc lamps being run off them with impunity. A number of other applications of this principle will readily suggest themselves, and it would seem to open up a new field of work for the alternating current.

One of the interesting signs of the interest taken in electricity at the present time is the amount of space that our magazines are devoting to it. Last year *Scribner's Magazine* made a great hit with a series of popular articles on the American railway system and its incidental features. These articles were contributed by leading experts, and conveyed a vast amount of information in a popular and pleasant way, doing much to clear up misconceptions and to give the public a broad and liberal appreciation of the good work that has been done in the railway service. *Scribner's* now proposes to bring out this year a series of articles on the same lines, dealing with electricity. These articles will give the public an idea as to what electricity is, what it can do, and what it cannot do, and will be contributed by a number of well-known men, including Prof. C. F. Brackett, Prof. Henry Morton, and Mr. A. E. Kennelly, of the Edison Laboratory. This series of articles will be read with much interest by electricians as well as by the public, and will undoubtedly do great good. Just recently the *Century Magazine* has had an excellent article by Mr. Charles Barnard on "Something Electricity is Doing," giving a graphic sketch of the lines of development of the electric motor industry; and this month the *Cosmopolitan Magazine* comes out with an illustrated article on "Edison," giving pictures of his house, his library, and his laboratory at Orange, and some interesting details of his career and of the manner in which he pursues his daily investigations at the laboratory. Another significant instance, as revealing the general desire to know something more of electricity, was given this month by the *Century* in publishing the prospectus of its magnificent new dictionary, which is to be issued in some twenty-four monthly parts, and will contain about 6,000 quarto pages. The sample page given to illustrate the style and nature of the contents is an electrical one. The fact that electricity should be the one topic thus picked out must, I think, strike anybody as significant.

In the article on Mr. Edison just referred to some interesting details are given as to the equipment of the now famous laboratory. It appears that one section is devoted to store purposes, containing hundreds of drawers and thousands of pigeon-holes, to fill which the whole of animate and inanimate nature appears to have been laid under contribution. The collection includes everything that it is possible to mention, Mr. Edison having tried to gather together samples of every material to be found in the habitable or explorable world. The collection is, therefore, a pretty costly one, and includes thousands of substances and packages that will never be used, but it is no doubt a great convenience to Mr. Edison to have all these materials ready to his hand whenever he is carrying on any new investigation. As an example of the manner in which delay is thus avoided at critical moments, reference is made in the article to the exhaustive researches that were gone into in finding the right kind of filament for the incandescent lamp, and more lately in finding just the right kind of needle for the vibrating diaphragm of the phonograph, a needle which, of course, has to possess peculiar properties of elasticity and rigidity. It would appear from this article that at this time Mr. Edison is carrying on some interesting experiments with a view of obtaining electrotypes of phonograms, so that they may be endlessly reduplicated. It would also appear from one or two casual hints in the article that Mr. Edison is giving up a great deal of his time to work in chemistry. This is probably the case, for he has more than once lately spoken of his great interest in that branch of study. The picture of the chemical room in his laboratory shows that it is generously supplied with material and apparatus.

CORRESPONDENCE.

THE EDUCATION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The number of our theoretically trained men that are being turned out yearly from our technical schools and colleges is rapidly increasing, and there is every sign of a still greater supply of one-sided electricians. It is therefore about time that some outcry was made against the misleading and rather highflown prospectuses that are constantly being sent to parents of the middle and upper middle classes regarding the short expenditure of time and the small expenditure of money required in qualifying for the profession of electrical engineering. There are several inaccuracies in these which do not escape the eye of a practical and commercial man. There is hardly any field nowadays for a man who has only spent a few months at a school where they teach the "best grouping of batteries" and other feats of mathematical gymnastics which never once in a hundred times occur in actual practice. Usually at the head of the letterpress there occurs some highly-coloured statement that anyone who has spent a short time in the laboratory will be at the expiration of the course a fully qualified electrical engineer, and will be able to command between £100 and £200 per annum. Very few well-trained men who have served a complete apprenticeship with a good firm will begin at anything like £100 per annum. It is a pity that the ministers, doctors, and lawyers into whose hands these missives should fall are so easily made to believe that their sons can be turned into trained electricians in the short space of time and at the small expense quoted by these gentlemen, and that without any workshop training or practical acquaintance with engineering. It is but useful now to mention one other point, and that is—the expression that this is "a field not yet overcrowded" may be the opinion of those who turn out book-learned electrical engineers, but it is not the opinion of those who are practically engaged in it. This one word of caution may do good in drawing attention to a state of affairs which is hardly creditable to those who have caused it.—Yours, &c.,

London, N., April 22. GERALD DAY.

GLOBULAR LIGHTNING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following is an account of an occurrence of "globular lightning" in Ealing between twelve and one o'clock to-day during a very severe hailstorm, as described to me by three or four eye-witnesses when I visited the spot this afternoon, and will I think be of interest.

A ball of fire "like a large football" came along the tops of the houses of St. Mark's-road; on the roof of No. 2 it dislodged several slates, a tile, and a lump of mortar weighing some 7lb. or more from the brickwork of a chimney, and then returned to the top of the road, where it burst. During its motion it is said to have rested for a moment upon a wash-house. The room just below the injured room was found to be full of smoke. I cannot gather whether its appearance was accompanied by any noise—some say not, and others that there was a clap of thunder; but I am inclined to think that a loud clap of thunder following a flash of forked lightning which occurred about the same time may account for the confusion of testimony.

All were agreed that what they called the thunderbolt was a round ball, very brilliant, and that it caused the destruction above described, which I examined for myself. Beyond this it is difficult to gather any reliable information, especially

Digitized by Google

as to its movements, as such a phenomenon would be very likely accompanied by optical delusions due to the persistence of its impression upon the retina of the eye after the image itself had vanished.—Yours, &c.,

EDWARD W. COWAN, Assoc.M.Inst.C.E.

1, Grange-park, Ealing, April 22, 1889.

[We should be pleased to hear from any of our readers who may have witnessed this discharge.—ED. *E.*]

PHOTOGRAPHS OF LIGHTNING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with much interest your report of Mr. Whipple's Paper on "Lightning Photographs," and as one of those who sent a "twisted ribbon" photograph to the Meteorological Society should like to say that in my case the window was wide open and nothing intervened between the lens and the flash, so his explanation will not apply in this case at any rate. There seems to me no reason to doubt that the photograph represents the actual path of the flash—indeed, it would surely be much more remarkable if the path of least resistance were in one vertical plane, even supposing there is no deeper reason for the spiral path. It is, I think, worthy of note that in the narrative of the Greeley Arctic Expedition the aurora streamers in certain cases are described as resembling twisted ribbons.

As regards the dark flash the "photographic" explanation of over-exposure is the simplest, and appears more likely than any error from careless printing, even supposing the effect could be got in the manner suggested, which seems doubtful; and even if it were done, it would be almost impossible to get two prints identical.—Yours, &c., A. K.C.

MIRRORS FOR GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Could any of your readers inform me what process is used in silvering glass to make very light mirrors for reflecting galvanometers?—Yours, &c., A. B. SMITH.

189, Maida Vale, W.,

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

March 27, 1889.

5,241. P. M. JUSTICE. London. Improvements in magnets, magneto-generators, and telephones (E. M. Greene, United States).

5,251. R. KENNEDY. Glasgow. Improvements in generating and storing electric energy.

5,282. A. H. GLADWIN. London. An electric time indicator, with or without calendar.

5,293. T. H. HICKS. London. Improvements relating to apparatus for the distribution and conversion of electric currents.

March 28, 1889.

5,300. K. G. GARBE and K. ROSS. London. Improvements in making electric bell pushes by pressing xylinite, celluloid, tortoiseshell, and other materials (which by process are made pliable) into any design required.

5,322. T. J. MURDAY. London. Apparatus for obtaining readings from indicators placed at a distance by the agency of electric currents.

5,348. W. E. AYRTON and J. PERRY. London. Measuring and regulating electrical frequency and currency.

5,357. J. J. RATHBONE. London. A novel construction or arrangement of appliances for measuring or ascertaining electric energy, and for recording the voltage or ammeter of currents.

March 29, 1889.

5,377. F. KING and W. P. MENDHAM. Bristol. Improvements in electrical testing instruments.

5,391. H. ARON. Liverpool. Improvements in the method of and appliances for insulating electric wires.

5,407. A. C. COCKBURN and H. W. HANDCOCK. London. Improvements in fuses and cut-outs for electric circuits.

5,423. F. KING. London. Improvements in conduits or supports for electric conductors.

March 30, 1889.

5,509. H. E. FENNER. London. Improvements in electric arc lamps.

5,511. W. BOGGETT. London. Improvements in obtaining electricity.

April 1, 1889.

5,515. A. W. COX and WALKER AND CO. Winchester. Improvements in telegraph instruments.

5,563. H. H. LAKE. London. Improvements in electric batteries (Lacombe and Co., France).

April 2, 1889.

5,612. H. H. LAKE. London. Improvements relating to the distribution of electric currents and to apparatus therefor (E. W. Rice, jun., United States).

5,615. J. A. TIMMIS. London. Improvements in the generation of electricity on railway trains.

5,621. H. H. LAKE. London. Improvements in and relating to electric induction coils or transformers (E. Thomson, United States).

5,640. A. J. BOULT. London. Improvements in or relating to electric railway signals (W. H. Waddell, United States).

5,656. H. WELCKER. London. A novel arrangement for conducting an electric current through the nose.

April 3, 1889.

5,676. D. REID and J. KEAN. Glasgow. Improvements in electric bells.

5,730. S. JOY and W. H. JOY. London. An improved combined ampere and voltmeter.

5,738. A. W. FITCH. London. Improvements in and connected with insulators for electric light and other wires (R. O. G. Drummond, South Africa).

April 4, 1889.

5,740. J. WOOD. Blackburn. Voltaic electric belt made with zinc and copper strips united to each other, to fit any part of wearer.

5,768. W. G. DE F. GARLAND. London. Improvements in wooden casings for electrical conductors.

5,774. R. P. SELLON and A. J. SPILLER. London. Electric lamps.

5,789. D. H. DAVIES and J. M. TOURTEL. London. Improvements in apparatus for effecting by insertion of a coin the production of electric light for a certain time.

April 5, 1889.

5,816. W. E. LANGDON. Derby. Improvements in electrical accumulator or secondary batteries.

5,832. G. HOOKHAM. Birmingham. Improvements in electricity meters of the pendulum class, parts of such improvements being applicable to other kinds of electricity meters.

5,839. T. H. ALLUM, G. C. FRICKER and J. R. BAINTON. London. Improvements in dynamo electric machines.

5,844. O. J. LODGE. Liverpool. Improvements in protecting telegraph, telephone, electric lighting, and other installations and instruments from damage by lightning or other high-tension electric currents, and in apparatus therefor.

5,858. B. OLLENDORFF. London. An improved tape-winding apparatus for use with telegraph-printing machines and other instruments.

5,867. A. GRAHAM. London. Improvements in connection with switches for telephone circuits.

April 6, 1889.

5,888. A. P. TROTTER. London. Improvements in methods of measuring electric resistance.

5,904. W. M. POPPLEWELL. London. Improved means and apparatus for electrically communicating between trains and fixed points or stations (F. Lefrançois, E. Manborque, and O. Boin, France).

5,912. C. J. VAN DEPOELE. London. Improvements in systems of suspending electric conductors. [Date applied for under Section 103 of the Patents' Act, 1883, 10th September, 1888, being date of application in the United States.]

5,913. C. J. VAN DEPOELE. London. Improvements in devices for establishing electrical contact in electric railways. [Date applied for under Section 103 of the Patents' Act, 1883, 7th September, 1888, being date of application in the United States.]

April 8, 1889.

5,955. E. W. LANCASTER. Birmingham. Improved ceiling rose or connector for electrical circuits and for the suspension of electrical fittings.

5,976. A. LEYLAND. London. An improved automatic electric alarm clock.

6,005. C. J. VAN DEPOELE. Liverpool. Improvements in carbon contacts or commutator brushes. [Date applied for under Section 103 of the Patents Act, 1883, September 7, 1888, being date of application in the United States.]

6,007. M. MCMULLIN. London. Improvements in the construction of electric brushes for curative purposes.

6,021. A. L. SHEPARD. London. Improvements relating to dynamo-electric machines and electric motors.

6,027. W. J. L. HAMILTON. London. Improvements in apparatus for governing, starting, stopping or adjusting steam, hydraulic and other motors and electric installations, and for regulating water-levels, the temperature of bearings, and for other regulating purposes.

Digitized by Google

April 9, 1889.

6,033. J. Abserdam. London. Improvements in the art of transmitting articulated speech by the agency of electricity without employing pulsatory, undulatory or vibratory electric currents on the line.

6,063. H. H. Lake. London. Improvements in and relating to safety devices for electric circuits (E. Thompson, United States).

6,064. H. H. Lake. London. Improvements relating to electro-magnets and to armatures for dynamo-electric machines or electric motors (E. Thompson, United States).

6,065. H. H. Lake. London. Improvements in and relating to electric motors (E. Thompson, United States).

6,078. F. A. Gobert. London. Improvements in electric arc lamps.

6,104. H. H. Lake. London. Improvements in the manufacture of filaments for incandescent electric lamps (J. B. Tibbits, United States).

6,112. P. A. Newton. London. Improvements in secondary batteries (W. Main, United States).

6,119. J. J. Shedlock and R. Mestern. London. Improvements in thermo-electric batteries.

April 10, 1889.

6,165. F. H. Berry. London. An improved electrical apparatus for periodically ringing bells or sounding alarms, and registering the same.

6,171. C. R. Heap. London. Improvements in means for regulating or controlling electric currents.

April 11, 1889.

6,195. G. H. Shepherd. London. Improved method of and means for constructing globes for incandescent electric lamps.

6,209. E. Liebert. London. An improved exciting liquid for use in electric batteries.

April 12, 1889.

6,231. W. E. Ayrton, J. Perry and E. W. Smith. London. Improvements in apparatus for producing electro-magnetic action with small self and mutual induction.

6,284. H. N. Prentice. London. Improvements in electric cut-outs.

6,285. H. N. Prentice. London. Improvements in dynamo-electric machines and electric motors.

6,286. D. Urquhart and W. Bates. London. Improvements in secondary batteries.

6,332. W. H. Scott and L. Paris and Scott (Limited). Norwich. Improvements in connection with electric fuses.

6,384. A. A. Goldston. London. Improvements in and relating to electric switches.

April 15, 1889.

6,410. R. A. Burnell. London. Improvements in galvanic cells for telephones (T. Wilms, Hamburg).

6,416. H. C. Nowell. Hammersmith. An improvement in electrical contact makers, or switches, or connectors, for the passage of a current of electricity.

6,423. A. J. Jarman. London. Improvements in electrical motors and apparatus connected therewith, especially applicable to purposes of locomotion.

6,429. C. Wells. London. An improved electric apparatus.

6,458. P. Hoho. London. Method of regulating the electric current produced by an electric machine driven by a motor having an irregular or variable speed.

April 16, 1889.

6,520. W. P. Thompson. Liverpool. Improvements in or relating to electrical motors for clocks and similar apparatus (G. and L. Hoppe, Germany).

6,527. H. H. Lake. London. Improvements relating to electro motor (N. Tesla, United States).

6,544. A. A. Goldston. London. Improvements relating to electric incandescence lamps.

6,547. S. C. C. Currie. London. Automatic circuit controllers for electric circuits.

April 17, 1889.

6,553. Sir W. Thomson. Glasgow. An electric energy meter.

6,557. J. N. Cooper. London. Improvements in cut-outs for electric circuits.

6,568. G. E. Dorman. Stafford. Improvements in dynamo electric generators and motors.

6,569. G. E. Dorman. Stafford. Improvements in dynamo electric generators and motors.

6,570. G. E. Dorman. Stafford. Improvements in dynamo electric generators and motors.

6,571. G. E. Dorman. Stafford. Improvements in dynamo electric generators and motors.

6,572. G. E. Dorman. Stafford. Improvements in dynamo electric generators and motors.

6,579. H. F. Jackson, A. Coleman and P. Loftus. Sheffield. A combined insulator and finial and lightning wire for telephone, telegraph, or other electric wires.

6,609. W. Boggett. London. Improved method and means for obtaining electricity.

COMPANIES' MEETINGS & REPORTS.

The Anglo-Portuguese Telephone Company (Limited).

The following is the report of the Directors of this Company presented at the adjourned second ordinary general meeting of shareholders held at the offices of the Company, 53, New Broad-street, E.C., on Thursday, April 25, at three o'clock:—

2. After making all deductions, the profit on the year's working amounts to £4,133. 2s. 2d., making with the amount carried forward from last year the total amount of £5,827. 19s. 7d. standing at the credit of profit and loss account. This amount it is proposed to carry forward to next year's account, to be dealt with hereafter as the Board may deem advisable.

3. The capital expenditure for the year amounted to £9,709. 16s. 9d. Your Directors beg to state that it has been necessary to build a new exchange in Lisbon in consequence of the increased number of subscribers, and also to make extended switchroom accommodation in Oporto, to open up new and improved routes, as well as other works undertaken at the instance of the Government Fiscal. It is on this account that such a large outlay of capital has been incurred. Your Directors have every reason to believe that the result will in the early future repay the outlay.

4. Your Directors are pleased to report that the issue of £10,000 Six per Cent. Debentures made in May last was successful, all the bonds being at once subscribed for.

5. The number of paying subscribers at December 31 last was:—In Lisbon 912, of a gross annual value of £6,625; in Oporto 721, of a gross annual value of £3,943; total, £10,568, showing a total increase in subscribers of 210, and in value of £1,268 over the preceding year.

6. A new law having recently been enacted which your Directors consider to be at variance with the terms of the concession granted to this Company, and which may possibly become somewhat harsh and vexatious in its application, your Directors are taking such steps in Portugal as they consider necessary to protect the Company's interests.

7. Dr. Frederic Clift having ceased to be a member of the Board, and an application on behalf of the debenture-holders having been made that they should be represented, Mr. C. L. W. FitzGerald, as representing that interest, has been elected to fill the vacancy.

8. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., being eligible, offer themselves for re-election.

Great Northern Telegraph Company of Copenhagen.

The financial statement of the Company for the year 1888 is just issued, and is as follows:—

The total receipts of the Company during the year, including the balance brought forward from 1887, amounted to	£329,119	8	3
Expenses	64,440	2	10
Net profit	£264,679	5	5
Payments already made:—			
5 per cent. interest on debentures (1881 and 1883 issues)	£16,000	0	0
Amortisation of 350 debentures	35,000	0	0
	£51,000	0	0

The Directors propose to distribute the balance of £213,679. 5s. 5d. as follows:—

Reserve and renewal fund	£55,555	11	1	
Pension fund of the staff	2,777	15	7	
Remuneration to the board of directors	1,500	0	0	
Interim dividends already paid	£75,000			
Final dividend proposed, making a total of 7½ per cent	37,500			
	112,500	0	0	
Balance carried forward	41,345	18	9	
				£213,679 5 5
				£264,679 5 5

The investments during the year on account of the reserve and renewal fund amounted to £37,218. 3s. 10d. The revenue fund on the 31st December last amounted to £573,792. 1s. 11d.

At the general meeting to be held at Copenhagen on the 27th inst., the following resolutions will be proposed:—(1.) "*That the report and balance sheet be adopted, and that discharge be given to the Board of Directors.*" (2.) "*That C. St. A. Bille, Esq., be re-elected as a member of the Board of Directors.*" (3.) "*That A. Berner, Esq., and S. Bille, Esq., be re-elected as Auditors of the Company.*"

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 12, 1889, amounted to £2,521, and for the week ended April 19, to £2,179.

CALLENDER'S BITUMEN TELEGRAPH AND WATERPROOF COMPANY (LIMITED).—The annual meeting of this company was held at its offices, 101, Leadenhall-street, on Wednesday, April 17, at 12 o'clock, Sir Geo. R. Prescott, Bart., chairman of the board of directors, presiding. We learn that a most satisfactory report of the year's working was presented showing a very large increase of business during 1888, and a dividend on the ordinary shares was declared, a substantial sum being also carried forward to the reserve fund. Sir Geo. R. Prescott and Mr. Henry Drake were re-elected directors, and the proceedings, which were unanimous throughout, terminated with a cordial vote of thanks to the directors and officers of the company.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 12, 1889, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £1,220, and for the week ended April 19, £1,057.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The traffic receipts of this company for the half-month ended April 15, 1889, were £3,732, against £3,012 for the corresponding period last year.

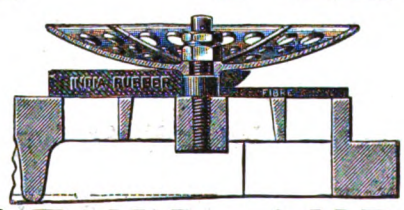
PERSONAL.—We understand that Mr. J. Swinburne has closed the lamp works at Chelmsford and gone into partnership with Earl Russell and Mr. H. S. Holt. Messrs. Swinburne and Co. have temporary premises at Teddington, and Mr. Swinburne's address for consulting work is 49, Queen's-road, Wimbledon.

——— The Telegraph Manufacturing Company (Limited) write us (confirming the announcement in our last issue) that Mr. J. Slater Lewis has resigned his position as managing director of the company, and has no longer any connection with or interest in the firm.

——— We are informed that Messrs. Dorman, Long and Co., steel and iron manufacturers, of Middlesbrough, have taken offices at 19, Victoria-street, Westminster, and that Mr. H. B. Powell will act as their representative.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature. Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Johnson & Phillips.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

MANVILLE & MADGEN, *Managing Directors.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 572.—Vol. XXII. FRIDAY, MAY 3, 1889. Price Fourpence.

NOTES.

The Board of Trade Inquiry terminated on Wednesday, having lasted eighteen days. The Inspector's report will probably be issued within a fortnight, and will be laid before the House in the usual way. If we escape a subsequent Parliamentary Inquiry we shall have much to be grateful for.

Some evidence of a rather singular character was given last week at the Board of Trade Inquiry in connection with what was termed "a provisional contract" between Messrs. Latimer Clark, Muirhead and Co. and the Westminster Electric Supply Corporation. The contractors undertake (provisionally) to equip a central station and distributing plant, "lamps and everything," at the rate of 30s. per lamp. Time was when it cost nearly as much to wire a house in good style, and now it appears that we can have our engines, and boilers, and dynamos, and underground mains thrown in. The station is designed for about 40,000 lamps of 10 candle-power. It may not be superfluous to mention that we learn further from the evidence that the provisional contract contains a clause to the effect that if the stipulated 30s. does not appear satisfactory when the work is done a fair price shall be fixed by arbitration. Here is an excellent opportunity for the Arbitration Committee of the Electrical Trades Section of the L. C. C.

The St. James' and Pall Mall Electric Light Company propose to lead the way in the establishment of Power stations in this country. They already hold a license from the Board of Trade for the distribution of electricity in the parish of St. James', Westminster, and their central station in Duke-street is now supplying current on a temporary circuit to the Salisbury Club. It is, however, the intention of the Company to erect a second station somewhere to the north of Piccadilly, which, it is given out, will be more particularly intended for the supply of motive power. It is just as well, perhaps, that an announcement of this kind should be made for the public benefit and to awaken interest in the undertaking; but the two stations will supply current to a common network, and there will be little or no technical difference between the one and the other. The three-wire system will be used.

Speaking of the three-wire system, we understand that the Hopkinson patent in this country has just passed into the hands of a company of American origin. What they mean to do with it we cannot say.

With reference to our remarks last week on the subject of Mr. Raikes' refusal to allow the Telephone Companies to transfer their licenses to a new company under the title of the Telephone Union, we are since informed that the license of the National Company, as well as that of the United, covers the whole country, and consequently that at least two of the existing undertakings might either of them assume the entire business. It happens, however, that the Articles of Association of the United Telephone Company do not permit it to acquire the business of a subsidiary company as a going concern, whereas there is nothing in the Articles of the National Company to forbid such an arrangement. On the other hand, the authorised capital of the National Company is not large enough to enable it to acquire the business both of the United and the Lancashire and Cheshire Company upon the terms agreed for the Telephone Union. At present the idea is to effect a reduction of about 16 per cent. all round, and to allow the National Company to absorb the two others upon this basis. Nothing has yet been finally settled, and it remains to be seen whether the powers of the Postmaster-General extend to a veto on these alternative proposals.

The Board of Trade edict relating to overhead wires has not yet been promulgated, though we believe that it may be expected very shortly. We have also reason to think that the conditions will be found to be of a thoroughly reasonable character, and not such as will in any way interfere with the legitimate development of the industries concerned.

In France the matter of an electrical standardising laboratory has passed beyond the stage of discussion at which it remains with us and entered that of practical operation. On the 9th of February last the *Société Internationale des Electriciens* inaugurated their central testing laboratory. A convenient site was secured in the Place St. Charles, Grenelle, in Paris, and a suitable building erected. Funds provided by the profits of the 1881 Paris Exhibition were set apart for this work, and M. de Merville appointed director of the laboratory, acting under the advice of a consultative committee of ten members. The laboratory consists of a number of rooms, each devoted to certain special standardising operations. Power is supplied by a 20 horse-power semi-portable engine, and current distributed to the various rooms from a secondary battery. In addition to these apartments there is a large hall in which special research work can be carried out. At the present moment Hertz's experi-

Digitized by Google

ments are being repeated and verified, and we had the pleasure last week of being witness to their repetition. The director and his assistant are aided by a staff of pupils in carrying on the routine work of the laboratory. Although the laboratory is even yet hardly completely organised, a varied range of important testing work has been carried out, and the demand for its assistance daily increases. The following is a list of the various classes of instruments which up to the present have been examined and tested :—Amperemeters and voltmeters (19), electro-dynamometers (2), resistances (6), condensers (6), meters (7), standard cells (5), secondary batteries (4), insulation of cables (14), conductibility of wires (21), conductibility of carbons (4), tests of machines (7), photometric values of lamps (6), the total being about 101 various determinations. It is in contemplation to use the laboratory not only for this commercial and scientific assay work but also as a place where experimental work of a quantitative kind can be carried out, and under certain circumstances to permit investigators authorised by the committee to carry out special researches on matters of public utility, or in which the apparatus of the laboratory affords particular advantages not to be obtained elsewhere. It admits of no question that a corresponding institution should be brought into existence in England without delay, and that a highly useful career exists for it, although it will be without doubt limited in the first instance, and wisely so, to the standardising and checking of instruments.

THE Telegraph Construction and Maintenance Company's ss. "Scotia" on the evening of April 30 completed the Mossamedes Cape Town cable. The northern sections having been previously laid by the India Rubber and Gutta Percha Company's ss. "Silvertown," this affords a direct alternative line of submarine telegraphic communication between England and the Cape of Good Hope. The whole of these cables—over 1,900 miles in length—have been laid by the two companies named without a single hitch.

IN his Paper on Secondary Batteries (read before the Society of Arts on Wednesday last), Mr. PREECE very truly remarks that "the character and quality of the electrolyte used in secondary batteries has hitherto scarcely received the attention it deserves." But during the last twelve months Mr. PREECE has himself been working in this direction, and he is now able definitely to confirm the statement, first made by Mr. BARBER-STARKEY in 1886, as to the value of sulphate of sodium as an addition to the ordinary sulphuric acid solution. Mr. PREECE has further determined the relative quantity of the salt which gives the best result, and in future he intends always to use this particular solution. Probably the majority of users of secondary batteries will be glad to follow his example. The text of the Paper will be found on another page.

THERE was a crowded audience on Thursday evening at the Institution of Electrical Engineers to hear Dr. LODGE "On Lightning, Lightning Conductors, and Lightning Protectors." Although this was the first occasion on which the Institution, as a body, has had an opportunity of witnessing the experiments of "the impulsive rush" and the oscillatory discharge, the leading features of Dr. LODGE's doctrine were probably already familiar to the majority of those present. One experiment of great beauty was, however, shown for the first time; this consisted in taking a long flash from the under surface of a metallic vessel having a perforated bottom, and filled with water so as to imitate a rain shower. It was then seen that at times the spark would split up into multitudinous branches, ramifying amongst the drops precisely as we see it in many lightning photographs. (*See*, for a particularly good example, a photograph reproduced in *The Electrician* of September 7, 1888, p. 556.) It will be remembered that at Bath it was suggested that this phenomenon was due to the actinic action of the lightning flash precipitating electric discharges in places where the dielectric was already strained, in the manner then lately discovered. It would be interesting to know whether this explanation is compatible with Dr. LODGE's recent experiment. The experiments with a gas jet were also new, and were highly suggestive in character.

IT is understood that the discussion on Dr. LODGE's Paper will be opened by Mr. PREECE, whose vigorous defence at Bath of the report of the Lightning Rod Conference will be fresh in the memory of our readers. (If not, they may look it up in *The Electrician* of September 21st and 28th, 1888). It appears to us, however, that Mr. PREECE will find it a task of increasing difficulty to maintain the position which he then took up. At that time it was admitted that the magnetisation of steel by the lightning flash was difficult to reconcile with the alleged oscillatory character of the discharge. Thanks to Prof. EWING (*The Electrician*, October 5, 1888, p. 712), that difficulty has now been removed. The doctrine of electrical oscillations is now so solidly established, and is so abundantly confirmed, that if Mr. PREECE still disputes its application to the lightning flash it must rest with him to show the reason why, and to show, moreover, how observed phenomena—such as side flashes, &c.—are to be otherwise explained.

AT Bath Dr. LODGE had to forego the advantage of displaying the experiments upon which his conclusions are based; but now that the Electrical Engineers have actually seen a point struck by a disruptive discharge, it will be difficult to make much capital out of the assertion that "no one has actually seen a lightning conductor struck by lightning." There is, moreover, evidence to the contrary. On July 10th, 1843, Prof. FRINK saw the conductor upon the summit of the spire of Strasburg Cathedral repeatedly struck by lightning—"stroke after stroke" (Dr. SESTIER, *La Foudre*, Vol. II., p. 451). This is only one out of a dozen similar instances recorded in the volume from which we quote. Is it possible that the Lightning Rod Conference were unacquainted with the invaluable record of facts (mingled, doubtless, with some fables) relating to thunderstorms, collected by SESTIER, and published at Paris in 1866? We should like to see an English translation of this

Digitized by Google

treatise, which affords a perfect mine of wealth for the illustration of the subject.

THE process of "pickling" sheet iron in the tin-plate manufacture, and the possibility of effecting a saving of material by the aid of electricity, has long afforded an interesting field for the researches of the electro-metallurgist, as well as a profitable source of revenue for the Patent Office. Though the actual quantity of material wasted per plate in the process of removing the rust from the surface of the iron by sulphuric acid is very small, yet, owing to the gigantic development of the industry, it represents many thousand tons of iron per annum. All sorts of devices have been patented for recovering the metal from the spent liquid, for removing the rust by electrolytic action, and avoiding loss by the transfer of a thin layer of the metal underneath from one plate to the other, and even for depositing a film of iron on the outside of a plate already coated with a film of the black oxide; but, at any rate until quite recently, all these efforts have resulted in failure. Some degree of success has, however, apparently attended the efforts of Mr. J. GUTENSOHN, who has for some time past been carrying out experiments upon a rather large scale at the Glarryrafron Iron Works, Clydach, near Swansea. It is claimed that the combined saving of metal and of acid effected by the process is sufficient to pay the entire charge on the electrical equipment, and to leave a balance of profit to the maker. Moreover, it reduces the amount of waste acid to be got rid of, which in itself is no small advantage. We sincerely trust that all that is claimed for Mr. GUTENSOHN'S process will be realised in practice. We may, however, remark that from certain figures which have come into our possession it would appear that electricity is only called upon to play a subordinate part in the operation; at any rate, the electrical energy actually employed appears to fall considerably short of what would be required to effect the operation by electrolysis pure and simple.

MORE reasons than one may be easily suggested for the failure of the Elieson Company to obtain a single bid for its patent rights. But apart from all other considerations, surely clause 10 of the conditions of sale was well calculated to cool the ardour of any would-be purchaser. It is therein stipulated that "if from any cause the vendors shall be unable to procure an assignment or transfer from C. P. ELIESON of any of the patents now in his name, the purchasers thereof shall be satisfied with and will accept an assignment of the beneficial interest therein, without requiring any assignment from the said C. P. ELIESON." Mr. ELIESON now asks us to state in justice to himself that he would have been glad to do anything to facilitate the sale, but that he was never even approached on the subject. The history of the Elieson Company has been an unhappy one from beginning to end. Although we have never been able to regard this system as the *beau ideal* of electric traction, yet the experience gained upon the North London lines was sufficient to show that under reasonably good management it would have resulted in a practical success. But, as with many other promising schemes in this country, technical considerations were over-ridden by the haste and greed of the commercial element, and failure is the result.

The Recent Thunderstorms.—The thunderstorms which have occurred in various parts of the kingdom within the last few days have resulted in several deaths from lightning.

St. James's Vestry.—At a meeting of this vestry last week formal permission was given to the laying of mains in certain streets by the St. James's and Pall-Mall Electric Light Company.

Newington Vestry.—At a meeting of this vestry last week it was decided to offer no objection to an application of the London Electric Supply Corporation (Limited) for a Provisional Order to supply electricity within the parish.

Institution of Electrical Engineers.—The Secretary of the Institution of Electrical Engineers informs us that the President and Lady Thomson intend to hold a *conversazione* for members of the Institution on Friday the 24th inst.

Inner Temple.—Since the abandonment of the large scheme which was being carried out by Mr. Sennett it has been decided to modify the existing installation, and the contract has been given to Messrs. Drake and Gorham, who formerly had this installation in hand.

Camera Club.—We are requested to mention that the third of the series of One-Man Photographic Exhibitions at the Camera Club will be opened on and after Tuesday, May 7, to visitors on presentation of card at 21, Bedford-street, W.C. The exhibition will continue for about two months.

Newington Vestry.—At a meeting of this Vestry last week it was formally moved: "That no objection be offered to the draft Provisional Order lodged by the London Electric Supply Corporation, or any action taken to watch the progress of the order through Parliament." The motion was carried.

The Royal Society.—The following Paper was read yesterday afternoon at the Royal Society, by Prof. J. J. Thomson, F.R.S., on "The Effect produced by Conductors in the neighbourhood of a Wire on the Rate of Propagation of Electrical Disturbances along it, with a determination of this Rate."

Folkestone.—The directors of the Folkestone Gas Company have refused to comply with the request of the Electric Lighting Committee that they should give up the lighting of the public lamps in the western part of the town, nor will they assent to any modification of or departure from the existing arrangement.

Electric Lighting Tenders.—The Streets Committee of the City Commissioners of Sewers will meet in the Guildhall on May 10th to receive the electric lighting tenders for the City. Further details will be found in our advertisement columns. Tenders are also wanted for a complete installation at Castle Mona Pavilion, Douglas, Isle of Man.

Presentation to Mr. J. D. Miller.—At the conclusion of a course of lectures on technical telephony, delivered during the winter by Mr. J. D. Miller, manager of the Dundee District of the National Telephone Company, to the male *employés* of the company, he was presented by them with a complete edition of the Waverley Novels and with a scientific work of reference.

Messrs. W. H. Willcox and Co.'s Catalogue.—We have recently received a very complete catalogue from Messrs. W. H. Willcox and Co., the well known oil refiners. Among the numerous varieties of lubricants we notice a moderately-priced dynamo oil and a special oil for gas engines. Messrs. W. H. Willcox and Co. claim that their lubricants are entirely free from the injurious acids so frequently met with in oils of the cheap and nasty type.

Chelmsford.—The Chelmsford Town Council have accepted the tender of Crompton and Co. (Limited) to light the public thoroughfares of the borough for five years with 18 arc lamps of 1,000 candle-power each and 200 incandescent lamps of 32 candle-power each, at a total inclusive cost of £873. 6s. 8d. per annum. The Council have, moreover, granted the company the exclusive privilege of lighting private houses in the borough by electricity during the term covered by the public lighting contract.

Battersea Vestry.—At a meeting of the Vestry last week attention was drawn to the great development of electric lighting, and the opinion was expressed that at the proposed Battersea Polytechnic arrangements could be made for lighting

Digitized by Google

the parish with electricity, and thus saving some £4,000 per annum. It was also proposed that an engine and dynamo should be fitted at the dust destructor for lighting the parish stables. Both proposals were referred to the Works Committee.

Copper.—The visible stock of copper, for the first time since December, 1887, has ceased to increase. According to Messrs. Merton and Co.'s monthly statistics the stock in England, France and afloat from Chili and Australia is 124,447 tons, a decrease of 429 tons for the month of April. The deliveries are 8,509 tons, being the largest of any month's record since 1887, and the price is lower than at any time included in modern records. The long lane has come to an end, but stocks are still enormous, engagements to buy are onerous, and altogether the market carries a heavy burden uphill.

Society of Arts.—The Papers set down for the ordinary meetings of this Society on Wednesday evenings after Easter are:—May 1, on "Secondary Batteries," by Mr. W. H. Preece, F.R.S.; May 8, "Origin and Manufacture of Playing Cards," by Mr. George Clulow; May 15, on "The Use of Spirit as an Agent in Prime Movers," by Mr. A. F. Yarrow; May 22, on "Automatic Selling Machines," by Mr. J. G. Lorrain; and May 29, on "The Science of Ventilation, as Applied to the Interior of Buildings," by Mr. D. G. Hoey. Mr. H. Graham Harris will commence his course of four Cantor Lectures on "Heat Engines other than Steam," on Monday evening, May 6.

Royal Institution.—At the annual meeting of the Royal Institution, held on Wednesday last week, the annual report of the Committee of Visitors for the year 1888 was read and adopted. The real and funded property now amounts to above £81,000, entirely derived from the contributions and donations of the members; 45 new members were elected, and 64 lectures and 19 evening discourses were delivered in 1888. The total number of volumes added to the library in the year was 866. The following gentlemen were unanimously elected as officers for the ensuing year:—President, the Duke of Northumberland, K.G.; Treasurer, Henry Pollock, Esq.; Secretary, Sir Frederick Bramwell, Bart., F.R.S.

Telegraph Company Amalgamation in the States.—The *Scientific American* states that the South Atlantic Telegraph Company, of Baltimore, Md., has been incorporated with a capital stock of $50,000. The new company is to form a link in the Mackay-Bennett and Postal Telegraph Cable Company system, and is for the purpose of purchasing and owning the lines of that system in Maryland, which are now only leased. The scheme embraces an amalgamation with the Southern Telegraph Company of Virginia, the Southern Telegraph Company of North Carolina, and the Southern Atlantic Telegraph Company, whereby lines of wire may be secured extending to New Orleans and covering the entire South and Southwest. This entire system is to be controlled by the Mackay-Bennett management.

Barnet.—At last week's meeting of the Barnet Local Board the Lighting Committee reported as follows:—"In reference to Mr. Joel's account for lighting, your Committee were of opinion that the allowance of £1. 1s. 6d. off the total amount of the bill of £95. 17s. was not sufficient. They calculated that as shown by the report of the expert who tested the lights there was a deficiency of candle-power amounting to about $\frac{1}{16}$, and after discussing the matter it was agreed by your Committee that this was the proper proportion to be taken off the lighting account. On this being pointed out to Mr. Joel he agreed to accept the sum of £90 in discharge of his account, thus allowing a reduction of £5. 17s. to the Board. Your Committee, under these circumstances, recommend that Mr. Joel's account be paid. Mr. Joel promised to see that the oil lamps at the junctions of the several streets were improved." The report was adopted.

Electric Apparatus Company's Catalogue.—The fifth edition of this Company's catalogue has been materially increased in size, and now forms a profusely-illustrated and well-arranged publication of some seventy pages. A few pages at the beginning are devoted to general hints as to the meaning of electrical terms, instructions for bell-fixing, &c. We notice, by-the-bye, on page 7, the following statement:—Current = ampere = volt × ohm.," which is, we suppose, a misprint. Some thirty pages are occupied with the prices and descriptions of a large variety of bells, batteries, pushes, fire and burglar alarms; quotations are also given for electric billiard-markers and electric water-level indicators. Prices are given of several types of influence machines, including the latest form of the Wimshurst. The last fifteen pages are devoted to electro-medical apparatus of the usual character. This catalogue is very complete as regards minor electrical apparatus, and the prices quoted seem in general to be very moderate.

Telegraphs and Telephones in Uruguay.—From a pamphlet issued by the Uruguayan Consul we extract the following information:—In 1887 there were the following telegraph lines in the Republic of Uruguay:—

	kilometres.
River Plate Company	233
,, (Cable) Company	160
Platino Brasilero Company	829
Oriental Company	636
Central Uruguay Railway Company (property)	315
	2,173

In 1888 the following lines were laid out:—

	kilometres.
National Telegraphs	942
,, (Cable)	11
The "International"	222
,, ,, (Cable)	47
North-Eastern Railway (property)	123
North-Western ,, ,,	177
	1,522

There are, therefore, 3,695 kilometres of telegraph wires, by means of which all parts of the Republic are in direct communication with each other. The Province of Santa Fé has 2,600 kilometres, 712 having been laid out last year, and in the Province of Buenos Ayres there are 6,636 kilometres, of which 173 were also completed last year. In 1887 the Compañia Platino Brasilera forwarded 36,642 private messages, that brought in $45,847; 3,539 press messages, $2,726; and 2,972 official messages, $9,136. In 1888 the company transmitted 42,088 private messages, yielding $48,118; 1,941 for the press, $1,997; and 2,765 official messages, $7,143. The two telephonic companies at Monte Video have the following number of lines and subscribers:—The "Uruguaya," late the "Gower-Bell" Company, has 1,796 subscribers and as many wires. The average of daily communications is 6,000. The Co-operative Telephone Company, although only recently formed, has already placed 105 instruments and laid out 430 wires, which are not all in working order on account of the scarcity of apparatus. Taking the population of Monte Video at 140,000, and the subscribers being 2,226, the proportion is 159 subscribers per 10,000 inhabitants, whereas in Berlin it is only 48, in Paris 21, and even in Buenos Ayres 65. We have more than double the number of telephones than Madrid, with a population of 398,000, more than three times than Lyons with 402,000 inhabitants, and almost six times as many as Marseilles.

Obituary.—The death is announced of Mr. Robert Stirling Newall, D.C.L., F.R.S., F.R.A.S., J.P., of Ferndene, Gateshead, whose name is well known in connection with the invention and manufacture of wire rope. Born in Dundee in 1812, of an old and respectable Scotch family, he entered a mercantile office, and afterwards came to London, where his talents found more congenial employment under the late Mr. Robert M'Calmont, in connection with experiments on the rapid production of steam. In 1840 Mr. Newall took out a patent for making wire rope; it was this invention that made submarine telegraphy possible. He established works at Gateshead, and his firm manufactured and laid the Dover and Calais cable in 1850, the Holyhead and Howth and Port Patrick in 1852, and the Dover and Ostend, the Frith of Forth, and the Holland cables in 1853. The Black Sea cable was laid by Mr. Newall in 1855, and the Red Sea cable in 1859. After laying the latter Mr. Newall was wrecked in the "Alma," when his courage and coolness proved of the greatest help to the shipwrecked passengers, He devoted much of his time to scientific work. He was twice Mayor of Gateshead, and he was unani-

mously asked to be mayor again this year, when the British Association visit Newcastle.

An Electric Railway Problem.—The Thomson-Houston Electric Company write from Boston as follows:—"We have just had to deal with a very peculiar problem which has arisen in the construction of one of our roads, the Cambridge Division of the West End Street Railway, Boston, Mass. It is illustrative of the mechanism used between the drawbridge and the main bridge, over which the cars are obliged to pass. It consists of two pairs of trusses, one at each end of the drawbridge, and one on the bridge adjacent, which suspend the overhead conductors, and at the end of which suspension are placed frogs, which come together in such a way when the draw is closed that the trolley cannot possibly jump the wire in passing from the conductor on the main bridge to that on the drawbridge. The overhead circuit and the circuit through the rails is completed by an armoured cable running underneath the bridge from side to side. The conductors on the bridge are supplied with current by an auxiliary cable which runs to the automatic switch, one-half of which is on the stationary portion of the pier and the other half on the movable portion of the draw. The connection at the switch is broken when the draw is open, as it is not necessary to have the current on the drawbridge, and is automatically closed when the draw swings in, so that the current can reach the overhead wires. This device has worked admirably since it was put down, and reflects a great deal upon the skill of the company's engineer who has charge of this construction work."

The City and Guilds Institute.—Lord Selborne presided on Tuesday at Mercers' Hall, Cheapside, over the annual general meeting of the governors of the City and Guilds Institute for the Advancement of Technical Education. In moving the adoption of the report the Earl of Selborne stated that there had been a decrease of 107 in the number of students attending the Central Institute compared with the previous year, but the decrease was more apparent than real. The progress made in the main work of the Central Institute had been very satisfactory, remembering that it was only opened in July, 1885. He thought it very satisfactory that in the great centres of commerce the operations of the Institute were evidently stimulating kindred operations. Referring to the technological examinations, he stated that they had always been, from a pecuniary point of view, a subject of some anxiety. The examinations really tended to regulate the instruction given throughout the country in all matters which came within the province of technical education, and their importance could not possibly be doubted. It might become necessary, as time went on and the examinations increased, for the local bodies where they took place to contribute to the expenses in connection with them. In 1888 the total number of students preparing for the technological examinations was 10,404; in the present year the number was 11,734. In 1887 the number of the classes was 365, in 1888 it was 473, and this year it was 505; and the towns in which the classes were held numbered in the present year 133. The examinations last year were in 49 subjects and in 240 centres. They had suffered a reduction of £4,000 a-year in their income from the separation from them of the Drapers' Company, from whom in the past they had received most generous support, and who they hoped would after the lapse of some time return to them. Valuable assistance had been received from the Fishmongers', the Clothworkers', the Skinners', and the Weavers' Companies, and the Institute had also received several donations in the shape of scholarships. In 1888 the subscriptions and donations received by them amounted to £24,960, but for the present year, he regretted to say, they could only reckon upon £22,495. The votes made, independently of the fees, came to £22,385 for the current year. Although fully appreciating the generosity of many of the companies, he really thought that the magnitude and importance of the work in hand were such that it ought not to be allowed to languish. Everything in connection with the Institute was encouraging, excepting the one matter of money. He hoped that they would receive greater support from the Corporation. The council claimed the credit of having given a notable impulse to the whole movement for technical education in London and elsewhere.

The Royal Society Selected Candidates. — Amongst the fifteen candidates recently selected by the Council of the Royal Society to be recommended for election into the Society the four gentlemen named below have distinguished themselves in electrical science:—

ALFRED BARNARD BASSET, M.A., barrister-at-law. Author of a treatise on Hydrodynamics, in two volumes (1888); also Papers in the *Quart. Journ. Math.*, *Mess. of Math.*, *Phil. Mag.*, *Proc.* Lond. Math. Soc., *Proc.* Camb. Phil. Soc., *Phil. Trans.* Roy. Soc. (1888), and *Amer. Journ. Math.* These Papers treat of the Motion of Liquids about Elliptic Cylinders, of Associated Functions and Spherical Harmonics, of Electric Currents of a Sheet rotating in a Field of Magnetic Force, the Potential of a Spherical Bowl, Motion of a Liquid Ellipsoid and Stability of this Motion, Motion of two Spheres in a Liquid, Potentials of Circular Disks, Motion of a Ring in a Liquid, Motion of a Sphere in a Viscous Liquid, and the Steady Motion of an Annular Mass of Rotating Liquid.

LATIMER CLARK, C.E., F.R.A.S., F.R.G.S., Electrical Engineer. Past President of the Institution of Electrical Engineers. Author of:—"Description of the Britannia and Conway Tubular Bridges;" chapter on "Tides of the Menai Straits," in E. Clark's book on the Britannia and Conway Bridges; "Elementary Treatise on Electrical Measurement;" and (jointly with R. Sabine) "Electrical Tables and Formulæ." Author of various Papers on Electric Measurement, and on various branches of Engineering Science, published in Report of the Brit. Assoc., the Government Report on Submarine Cables, and the Engineering Journals. Introduced a standard voltaic cell of great importance and value for promoting accurate measurement of electric potentials, and presented a Paper on this subject to the Royal Society, which was read June 19, 1873. From 1848-51 was Resident Assistant Engineer at the Britannia Tubular Bridge, under the late Robert Stephenson. In 1851 became Engineer to the Electric and International Telegraph Company, and remained in this service for twenty years, part of the time as Engineer-in-Chief. Made important observations on the passage of electricity through long underground lines, of which the results were the subject of Faraday's Bakerian lecture of 1854, and are given in his "Experimental Researches," with Faraday's own experiments and theory. In 1854 introduced the system of transmitting messages through "pneumatic despatch tubes" in the Electric Telegraph Company's service. The system is continued in the Postal Telegraph system of the Government, having been found admirably successful and useful.

CHARLES TODD, M.A. (Cambridge), C.M.G., F.R.A.S. Postmaster-General, Superintendent of Telegraphs, and Government Astronomer. He has executed important astronomical observations extending over thirty-eight years, including Transit of Venus, Jupiter's Satellites, Determinaton of Australian Longiudes, &c. He has conducted Meteorological Observations in South Australia, extending over thirty years. He has written a Treatise on the Meteorology of South Australia, and other works. He has contributed Papers to the Royal Society of South Australia, and was responsible for the erection of the telegraph line across the interior of Australia from Adelaide to Port Darwen, 2,000 miles in length, and to Western Australia, 1,000 miles in length.

HERBERT TOMLINSON, B.A. (Oxford), formerly Junior Student of Christ Church, Oxford; Whitworth Exhibitioner, 1870; Demonstrator of Natural Philosophy in King's College, London; author of numerous Papers on physical subjects published in *Phil. Trans.*, *Proc.* Roy. Soc., *Phil. Mag.*, &c., the most important of which relate to the influence of stress and strain on the Physical Properties of Matter. The following may be enumerated:—(1) "Effect of Magnetisation on the Electrical Conductivity of Iron" (*Proc.* Roy. Soc., 1875); (2) "Increase in resistance to the passage of an Electrical Current produced in certain wires by Stretching" (*ibid.*, 1887); (3) "Alteration of Thermal Conductivity of Iron and Steel caused by Magnetism" (*ibid.*, 1878). The following Papers relate to the influence of Stress and Strain, &c.:—(4) "Moduli of Elasticity" (*Phil. Trans.*, 1883); (5) "Electrical Conductivity" (*ibid.*); (6) "Relations between Moduli of Elasticity, Thermal Capacity, and other Physical Constants" (*Proc.* Roy. Soc., 1885); (7) "Alteration of the Electrical Conductivity of Cobalt, &c., by Longitudinal Traction" (*Proc.* Roy. Soc., 1885); (8) "Internal Friction of Metals" (*Phil. Trans.*, 1886); (9) "Coefficient of Viscosity of Air" (*ibid.*); (10) "On Certain Sources of Error in Connection with Experiments on Torsional Vibrations" (*Phil. Mag.*, 1885); (11) "Temporary and Permanent Effects on some of the Physical Properties of Iron produced by raising the Temperature to 100° C." (*ibid.*, 1886); (12) "Effect of Change of Temperature on the Internal Friction and Torsional Elasticity of Metals" (Abstract in *Proc.* Roy. Soc., 1886); (13) "Effect on Magnetisation on the Elasticity and the Internal Friction of Metals" (*Phil. Trans.*, Vol. CLXXIX., p. 1); and other Papers.

THE USE OF THE INTEGRAPH IN DETERMINING SOME PROBLEMS IN ELECTRO-DYNAMICS.

BY L. B. ATKINSON.

(Continued from page 703.)

In the case of two electric circuits each having a coefficient of self-induction and a coefficient of mutual induction between them the equations are of similar form to equation (1), but the equation for each circuit includes a term depending on the rate of change of the current in the other circuit.

Calling E and $E_{,}$, C and $C_{,}$, R and $R_{,}$, L and $L_{,}$ the corresponding coefficients for the two circuits, and M the coefficient of mutual induction, the equations are

$$L\frac{dc}{dt}+CR-M\frac{dc_{,}}{dt}=E \text{ for the primary,}$$

$$L_{,}\frac{dc_{,}}{dt}+C_{,}R-M\frac{dc}{dt}=0 \text{ for the secondary,}$$

where $M\frac{dc}{dt}$ is, of course, the value of $E_{,}$.

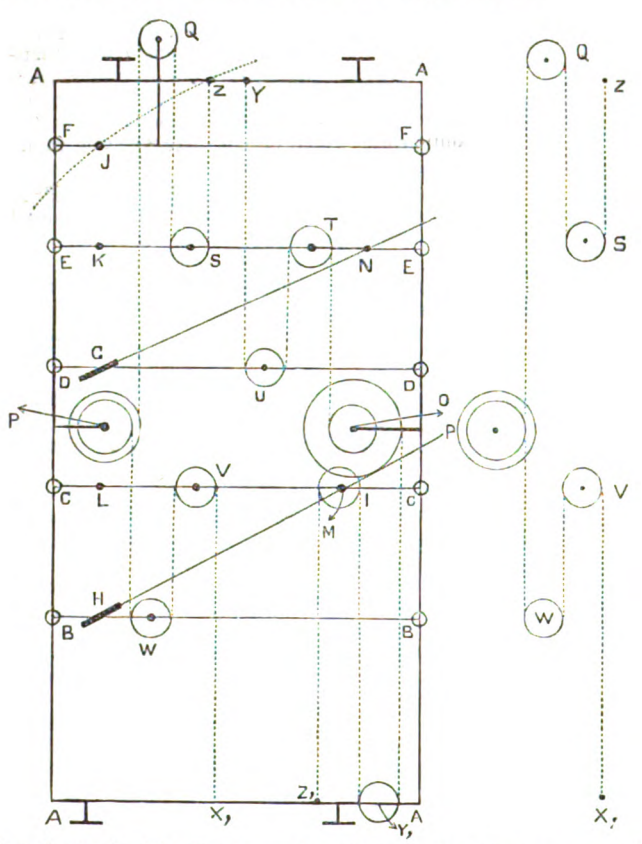
These equations may be written

$$L\frac{dc}{dt}+CR=E+M\frac{dc_{,}}{dt},$$

and

$$L_{,}\frac{dc_{,}}{dt}+C_{,}R=M\frac{dc}{dt},$$

when it is obvious that they are similar in form, and therefore may be dealt with by an integraph on a similar principle to that described for use in the case of a single circuit.



FIGS. 4 AND 6.—The Roman capital letters on the figures correspond to the italic letters in the text.

The problem now is to construct an integraph to mechanically draw the curves showing the relations between C and t, $E_{,}$ and t, $C_{,}$ and t, when the only curve given is that expressing the relation of E and t, the constants of the circuits being also given.

Proceeding as before by an analytical process, the skeleton construction of such an integraph will first be described; it will then be shown that the curves traced correspond to those defined by the above equations.

Fig. 4 is a skeleton drawing of the integraph, $a\,a\,a\,a$ is a frame supported and moving on guides or rollers parallel to the axis O X. In this frame are five cross slides $b\,b$, $c\,c$, $d\,d$, $e\,e$, $f\,f$, capable of moving parallel to the axis O Y; f carries at j a tracing point which follows the given curve of impressed E.M.F., e carries at k a point which traces the resultant E.M.F. in the primary, d carries at g an integrating wheel pivotted and guided by the rod $g\,n$ in the manner previously described, following the curve of primary current, c carries at l a tracer, which draws the curve of induced E.M.F. in the secondary, l carries an integrating wheel which follows the curve of secondary current. The sliding rods f and e are connected round rollers by a cord fixed to the frame at z and wound on a roller p. Another roller on the same axis carries a cord passing round rollers on the sliders b, c, and fixed to the frame at $x_{,}$. A similar set of cords and rollers embraces the pair $d\,e$, through the rollers on the axis O, and embraces the slider c and the fixed frame at $z_{,}$.

Fig 5 shows the geometry of the integrating mechanisms.

Fig. 6 shows one system of cords and pulleys dissociated from the rest of the mechanism in order to show its function, as follows. The points z and x being fixed, and the radii of the larger and smaller rollers at p being r and $r_{,}$, any variation λ in the distance between s and q is accompanied by a variation $\lambda_{,}=\frac{\lambda r}{r_{,}}$ in the distance between w and v, whilst at the same time w and v as a pair, or s and q as a pair, can move up or down, each pair independently of the other pair. Similarly, in Fig. 4 any variation in the distance $u\,t$ is accompanied by a variation in the distance $z_{,}\,i$ in inverse ratio to the diameters of the rollers at O. Springs, not shown in the diagram, keep these cords always tight.

It may now be shown that the double integrating system with connecting cords as described, fulfils the required conditions.

The setting of the points n and m are such that

$$k\,n=\frac{L}{R} \text{ and } l\,m=\frac{L_{,}}{R_{,}},$$

and the radii of the rollers on p are in the ratio $\frac{L_{,}}{R_{,}}:\frac{M}{R}$,

the radii of the rollers on A O being in the ratio $\frac{L}{R}:\frac{M}{R_{,}}$,

and the movements of the several cords attached to the rollers are inversely as these ratios.

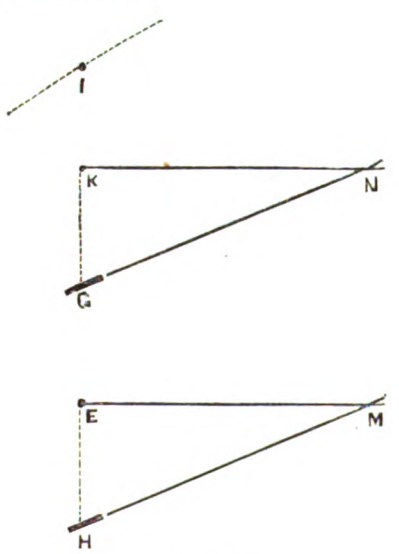


FIG. 5.

The positions and movements of the parts may be analysed as follows:—The point j follows the curve of impressed E.M.F. (drawn to a scale such that $e=\frac{E}{R}$). The point R moves thus, the co-ordinates being $E_{,}$ and t:—

$E_{,}=e+(s\,q-\lambda)$, where λ is a constant depending on the initial length of the cord,

$$=e+\frac{M}{R}\frac{R_{,}}{L_{,}}w\,v,$$

Digitized by Google

and $w\,v = (z_1 i - \mu)$ where μ is a constant depending on the initial length of the cord

$$= \frac{L_1}{R_1}\frac{dc_1}{dt},$$

c_1 and t being the co-ordinates of the point (v);

hence $$E_r = e + \frac{M}{R}\frac{dc_1}{dt},$$

which is the resultant inducing E.M.F. in the primary, divided by the resistance R.

The integrating roller (as has been previously shown) follows the curve—

$$\frac{dc}{dt} = \frac{\left(e + \frac{M}{R}\frac{dc_1}{dt}\right) - C}{\frac{L}{R}} = \frac{\frac{E}{R} + \frac{M}{R}\frac{dc_1}{dt} - C}{\frac{L}{C}},$$

which, being re-written, gives

$$L\frac{dc}{dt} + C\,R = E + M\frac{dc_1}{dt},$$

the curve of primary current.

The point v traces (under the control of the cord $z\,i$ and pulleys on O) a curve, the co-ordinate of which,

$$e_1 = \frac{E_1}{R_1} = z\,i - \mu = \frac{M}{R_1}\frac{R}{L}gk = \frac{M}{R_1}\frac{dc}{dt},$$

which is the induced E.M.F. in the secondary divided by R_1; and, finally, the integrating roller w follows the curve (as before shown).

$$\frac{dc_1}{dt} = \frac{e_1 - C}{\frac{L_1}{R_1}} = \frac{\frac{M}{R_1}\frac{dc}{dt} - C_1}{\frac{L_1}{R_1}},$$

which re-written is

$$L\frac{dc_1}{dt} + C_1 R_1 = M\frac{dc}{dt},$$ the curve of secondary current.

It may be noted that the particular connecting mechanism between the two integrating systems here described is only suggestive: other and possibly better ones could be adopted. The brief description here given suffices, however, to show the possibility of constructing an integraph to completely exhibit the variation of E.M.F.'s and currents in two circuits under any assumed law of impressed E.M.F. In a further short article the writer proposes to show some further uses to which this class of integraph can be put in solving problems of electrical calculation.

(To be continued.)

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"On Lightning, Lightning Conductors, and Lightning Protectors."*

BY DR. OLIVER LODGE, F.R.S.

Introduction.

About this time last year I delivered two lectures to the Society of Arts on the subject of "Lightning Conductors," in pursuance of a bequest made to the Society in memory of the late Dr. Mann. In those lectures I abstained, as far as possible, from practical recipes, and from anything like authoritative advice, contenting myself with calling attention to certain aspects of the subject which had been overlooked. I ventured to imply that none of the older electricians had any notion of the real conditions of the problem; that they all, from Franklin to Faraday, and down to the present day, treated it as a much easier matter than, in fact, it is, and that there had been very little real progress in this particular department since the time of Franklin.

Recent advances in electrical theory made it easy for me to see further into the matter than the far greater men of the past had had any chance of doing; and a few very simple and easy experiments soon brought the conditions of the problem clearly before me.

It was these conditions upon which I laid emphasis in my lectures to the Society of Arts. Any practical outcome I left to a later period, and very likely to other hands. The first requisite seemed to be to grasp the conditions of the problem as illuminated by theory; the second, to carry out practical reform in the light of a large experience.

Such few practical recipes as I did surreptitiously introduce I fully expected to hear criticised, nor did I lay any stress on them at the time. (I may say, however, that I have seen no occasion since to modify any of them, and that my position in respect of these practical hints is stronger now than it was then, inasmuch as I find that the large experience of the Belgian electricians, who have given more attention to this subject than perhaps any other school, has led them to recommend in recent years almost precisely the same methods of protection as those I advocated, their views being acquired almost entirely by practical experience and scarcely at all by theory.)

The theoretical and experimental portions of my lectures were, however, matter of serious consideration with me, and nothing was set down under these heads but that of which I was absolutely sure. These portions have by all pure physicists been, so far as I know, universally accepted; as, indeed, they contain nothing but what any one of them could have easily arrived at had he happened to give sufficient thought and attention to the subject. They have not been attacked, nor do I believe they are at all attackable from the side of theory.

But from the side of experience an attack has come, and, strange to say, it has been directed, not at the few practical suggestions, which might be expected to be vulnerable on that side, but at the theoretical and purely scientific portions.

At the Bath meeting of the British Association the then President of Section G (Mr. Preece), speaking in the light of a most gigantic experience—a personal acquaintance with over half-a-million conductors—led a most good-humoured attack against the doctrine of my lectures, and, exercising his well-known rhetorical and oratorical powers, succeeded probably in impressing the general bulk of the audience with the belief that he had, on the whole, the best of the battle; though, at the same time, I expect they were in a state of utter bewilderment as to what the conflict had been all about, and where the difference "'twixt tweedledum and tweedledee" precisely lay. The battle was, however, admittedly a drawn one, and at its close Mr. Preece magnanimously offered me another field, with an audience of an altogether different calibre to the general public of Bath, by getting your secretary to invite me to read a Paper before this Institution.

Thus much by way of historical note and introduction. Now for the scientific portion of the Paper.

I begin by running over some of the conclusions at which I arrived, and proceed to re-establish and demonstrate their correctness either by theory or by fresh experiment, whichever may seem the more simple and satisfactory under the special circumstances.

Two Main Cases of Lightning Flash.

1. All discharge is virtually that of a Leyden jar. There are always two conductors separated by dielectric, and the discharge is a breaking down of the dielectric at its thinnest or weakest place.

In a thunderstorm the charged conductors are obvious, being either two clouds, or else a cloud and earth, and the dielectric is the air between.

2. It must sometimes happen, when one cloud discharges into another, that the potential of this other is suddenly raised high enough to cause it to discharge into the earth, even though no strain previously existed in the air between it and earth. The same thing may happen in various other ways when two clouds spark into each other, as indicated by the diagram (Fig. 1).

3. There are, therefore, two main cases—(*a*) When the strain in the dielectric near the earth has been of gradual growth, in which case the path of discharge will be prepared inductively beforehand; (*b*) when the strain arises so suddenly that there is no time for any pre-arranged path. The first I call "steady strain," the second "impulsive rush." It is most important to recognise these two cases, and to understand the extremely different conditions attending the two. The first case only was ever contemplated by the older electricians; in fact, so far as I know, it was my experiments last year which first called attention to the other case.

Conditions of Protection and of being Struck, under the Circumstances of each Case.

4. I will now illustrate experimentally the conditions under which discharge occurs in each of these two main cases, and I will take first the case of steady strain, or case *a*. This insulated sheet of tin plate is supported horizontally a foot or two above another plate lying on the table, and it is electrified by a Wimshurst machine. It represents a charged cloud hovering over the land, the lower plate representing the earth. Between the two I can

* Paper read before the Institution of Electrical Engineers on Thursday, April 25, 1889.

Digitized by Google

erect buildings, and lightning conductors terminated in various ways. The typical terminals which I will here use to illustrate the conditions are four, viz., a large knob, or, as I shall call it, a "dome;" a small knob, which I shall call "knob;" a sharp point, and a gas flame to represent a chimney or other furnace current of rarefied air. Putting the knob and the dome between the plates, we find the knob struck by preference, even though the dome stands at a much higher elevation. Introducing the point, we find it protects both, by a silent discharge, until it is lowered very considerably; and that then several points may protect when one does not. Replacing the point by the flame, we find that it protects too, but not so efficiently as the point, and that it gets curiously beaten down and darkened in the act of protection. The point is not struck by a noisy flash until it is raised pretty close to the upper plate, when it is struck; but a bunch of points is even then not **easily struck, sometimes continuing to discharge silently right up almost into the cloud.**

5. Try the effect of a bad earth or other very high **resistance** interposed in the path of the conductor, say a capillary **water tube,** or a bit of wet rag, or a wet string.

The violence of the spark is lessened, and the sound **is now** gentle, but that which was struck before is still struck; **resistance,** so long as it be something short of infinite, makes no **difference to** the ease with which a given object is struck under **the circumstances** of this case 1. Insert the wet rag in path terminated by point, and it still protects, practically as well as before. **Insert it** in path terminated by knob, and it gets struck at the same **elevation** as before.

The fact is that the path of the disruptive discharge is all **negotiated** and pre-arranged in the air above, especially on the **surface** of any small conductor reared into this space, and the **resistance** which the flash may ultimately have to meet with in its passage to **earth is a thing of subsequent consideration.**

6. **So much for the conditions attending case *a*, the steady strain,**

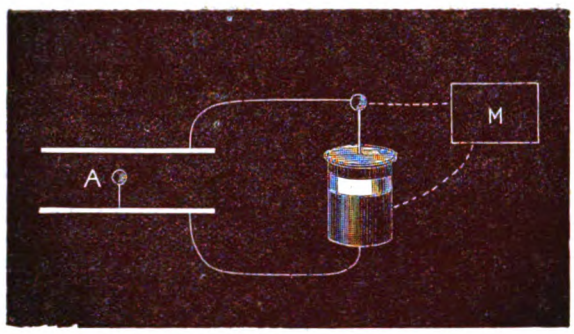

FIG. 1.—Case *a*.

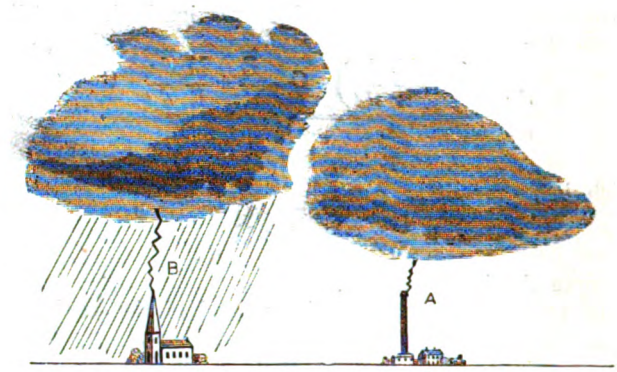

FIG. 2.—Case *a*.

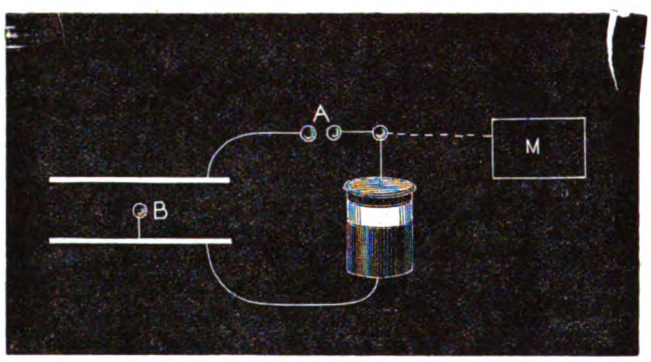

FIG. 1.—Case *b* (1).

FIG. 2.—Case *b* (1).

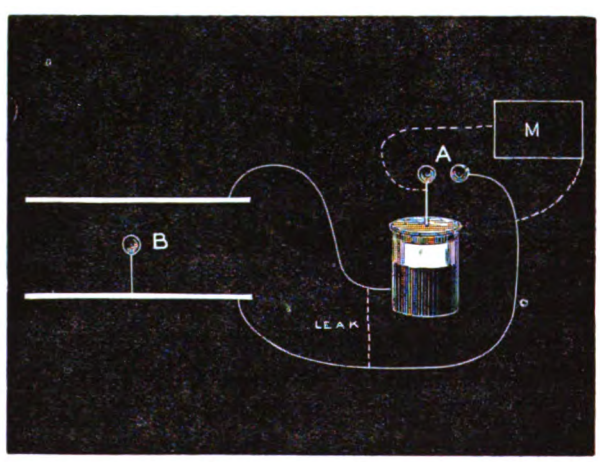

FIG. 1.—Case *b* (2).

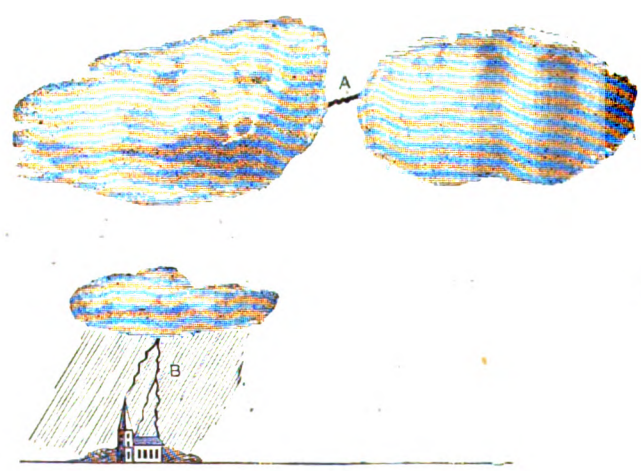

FIG. 2.—Case *b* (2).

Figs. 1 and 2 represent the same conditions as they may occur in nature and as they can be arranged artificially. Case *a* in each figure is the steady-strain case. The others are varieties of the impulsive rush, where a spark at A precipitates a spark at B, the place where B occurs having been subjected to no preliminary strain. Clouds correspond to coatings of jars; spaces between them correspond to glass or other insulating space. The position of the charging machine M is indicated in Fig. 1 for convenience.

The leak or imperfect conductor in the second case *b* of Fig. 1 is needful in order that the jar may charge. It takes no part in the discharge. Its place is taken in Fig. 2 by the rain-shower. In case *b* the rain-shower or leak are permissible but unnecessary.

Digitized by Google

Now attend to case *b*, the impulsive rush. We shall find everything very different.

Alter the connection so that a charged Leyden jar must, when it discharges, discharge direct into the upper insulated tin plate, and thence overflow to the ground if it is able to raise the potential high enough. If the plate is too far above ground for a flash to occur, the Leyden jar does not completely discharge ; it only produces a number of fizzes and spits, and the greater part of its charge remains in it. But when the upper plate is within sparking distance of the ground (and the sparking distance under these circumstances is surprisingly great by reason of the impetus with which the electricity rushes into the top plate), then the jar discharges completely, and we have a violent crack both between the knobs of its discharger and in the air gap between the two plates which is in the path of the discharge, the arrangement being really two condensers in series but only one charged.

The only object of the Leyden jar in case *a* is to give more body to the flash. In case *b* the Leyden jar, or it equivalent capacity, is essential.

7. Putting the dome and the knob between the plates arranged as in case *b*, we find that one gets struck as easily as the other ; the knob has now no advantage : whichever is the higher that gets struck, without reference to other considerations. Introducing the point also, we find precisely the same is true for it ; its protective virtue, so much insisted on by the older electricians (among whom I suppose I am right in reckoning my chief antagonist), is entirely non-existent. It gets struck no more easily, and no less easily, than the dome, and it gets struck by a flash of precisely the same noisy character as the others get struck with. A bunch of points acts in exactly the same way. A comb of 24 needle points protects nothing, and gets struck just the same as anything else.

8. Now introduce the flame, and one notices a marked difference. In case *a* it protected less well than the point, but it was not struck noisily any more than the point was. In the present case it gets struck with violence, and it gets struck much more easily than anything else. Adjust dome and knob and point at about the same level, and they get struck, one or other, at random. Adjust the flame a great deal lower, and it protects them all, not by silent discharge, but by getting struck itself instead.

"Protection," however, is in this case not the word to use. The flame better represents a chimney requiring protection, while the point corresponds to the pointed terminal of a lightning conductor raised a good deal higher with the intention of protecting it. Protect it it does not, however ; the flash strikes down the column of hot air and through the flame, while it avoids the more lofty pointed terminal altogether.

Bring a point or a knob, or anything, *into* the column of hot air above the flame ; *then* it gets struck easily enough, and protects the flame, but not if it is on one side of the hot-air column. The experiment has an obvious moral in relation to the protection of chimneys ; it suggest that the Continental plan of a bar or arch across the mouth of the chimney may, after all, be justified.

9. Try the effect of resistance in the path of the discharger *now*, and we find it is altogether different to what it was in case *a*.

In case *b* things get struck according to their height, independent of the shape of their terminals, but not independent of their resistances.

Interpose a wet rag in the path of any one, and that one fails to be struck ; it is not struck, and it fails to protect the others from being struck, even though it be reared up till it touches the top plate.

The top plate need not therefore be insulated at all carefully for this case *b* experiment.

Imitation of Lightning.

10. Now let us modify case *b* by making the top plate a sieve full of water, so as to get the flashes in a shower of rain. One cannot well try case 1 in a rain shower : the plate would be discharged too rapidly and continuously by the water-drops for its potential to fully rise. But in case 2 the top plate is not necessarily charged at all until the rush comes, and so the rain shower does no harm.

Flashes in the rain can be got of surprising length and shape, for they make use of the water-drops as stepping-stones. By adding salt to the water they become longer still, but there is no need thus to improve its conductivity for what I want to show.

Notice how the flash contorts itself, taking sometimes extraordinary paths as it jumps from drop to drop, but yet exhibiting its instantaneous character by showing the drops as stationary in its illumination.

11. Remove the things standing on earth-plate just beyond fair striking distance, and what do we see ? Appearances precisely like those which are observed in many lightning photographs.

A crowd of violent discharges fill the rainy air—forks, and branch and multiple flashes, not very bright or very noisy, but extraordinarily numerous, and striking on innumerable places at once. A riot is set up in this air at every attempt of the jar to discharge, exactly as happens in one of the most striking of the photographs belonging to the Royal Meteorological Society.

Masts and spars and deck and ocean may be simultaneously struck by these interesting flashes, and though they do not here appear very violent, yet I expect that on the larger scale of Nature they are not very safe, and may easily have a heating effect sufficient to ignite bodies. These experimental ones are able to ignite gas in the midst of the rain.

12. While we have this arrangement at work we may as well try an interesting little experiment on what happens when lightning reaches water. The rain water has here been collected in a zinc tray some three inches deep, and by bringing a knob from the top plate, some six inches or so above the water, a flash strikes it. It prefers to strike anything metallic if it can, but if there is nothing else within reach it will strike the water. On reaching the water the flash forks out and ramifies in all directions in a crow-foot pattern, giving the same sort of appearance, only coarser, as that obtained by Mr. J. Brown by taking sparks on to a photographic dry plate and then developing.

Bring the knob nearer and nearer, the same thing happens, until the water is touched by the knob, and even after it is submerged. But as soon as the metallic conductor is submerged the ramifications get less and less vigorous, and when a sufficient surface is immersed they cease. I have never seen these ramifications spread of themselves *below* the surface of the water. They appear to me to keep entirely to the surface. But I have not yet finished investigating these appearances.

13. Immersing a half-full beaker in the water, sparks can be got to the water inside it, though they prefer to curl round and go outside. The noise the sparks make when they go inside is a curious one, and sounds as if the glass cracked each time, but it does not. If the glass is moist, a brush cascade round its edge can be seen in the dark. If it be dry, the water inside gets charged, and fizzes audibly back to the knob for a second or so after the spark has ceased, a dimple being visible in the water below the knob.

14. Live things in the struck water—worms, flies, fish, &c.—will most certainly get struck ; but so they do under far less violent disturbances than what they would here be subject to. There is nothing surprising in the fish of a pond or lake being killed by a flash of lightning ; and it has often happened.

When H.M.S. "Conway" was struck many years ago, and protected by its lightning conductors, it is related that the sea-water was seen to be luminous on all sides of the ship. This is exactly the effect I now imitate.

15. There is one more experiment on discharge in water which I have just tried, and which it is interesting to show.* I take a painted rod, and, protecting it by a glass tube, immerse its point under water in a beaker containing a plate connected to the other coat of the jar, and pass a spark. With the point negative there is a bright glow region round it every time, but the discharge is quiet. With the point positive, the flash is of a dazzling white, and is accompanied by a great deal of noise and violence, threatening to smash the Leyden jar, and throwing down the copper plate towards the bottom of the beaker with fury.

Oscillatory Character of Lightning.

16. Before leaving the outdoor department of our subject I must say a few words on one branch of it concerning which there is evidently considerable uncertainty and haziness abroad—I mean the oscillatory character of a lightning flash.

That a Leyden jar discharge is usually oscillatory must now be regarded as so extravagantly proved that any doubts that may have existed on the subject must surely by this time be cleared away, at least for the case where the discharge has to utilise a wire circuit. But perhaps it is still doubted for the case when a jar overflows its edge, or, still more, when it merely sparks through its own dielectric straight between the coatings.

Now, as I have insisted all along, a lightning flash is a spark through the dielectric of a jar whose two coatings are either two clouds, or else cloud and earth. Hence, if any importance is attached to the fact (as I believe it) that lightning flashes are oscillatory it is necessary to prove it for a Leyden jar sparking direct between its coatings, especially when the coatings are not very close together.

17. The reason I do attach importance to the oscillatory character of a discharge is because I have worked out the quantitative behaviour of conductors on that aspect of the matter ; and though, as Prof. Fitzgerald said at Bath, everything would hold just as well for a single oscillation—viz., one violent rise and decay of current (which without any doubt *must* accompany a lightning stroke or any other quick discharge whatever)—if rapid enough, yet the rapidity of such a charge as this does not seem to me prob-

* This experiment was not shown at the meeting, because in trying over in the afternoon the protecting glass tube was electrically broken.

Digitized by Google

ably at all sufficient to account for some of the effects. The rapidity of variation of current in that case would be directly connected with the total duration of the flash ; and though we have evidence that it is very momentary, yet we have no evidence that it is so instantaneous (say a millionth of a second) as the semi-period of one of the oscillations may be, a dozen or more of which may accompany an entire flash. However, I admit, of course, that all I want is a tremendously rapid variation of current, and if I can be given this by one oscillation, the rest are unnecessary, and may be dispensed with.

18. When I speak of the oscillatory character of a flash, let it be understood once for all that I do not mean in the least such a thing as can be analysed by waggling the head. Flashes analysable by waggling the head must be multiple ones, and the interval of time between their constituents (which may be, say, the fiftieth of a second or thereabouts) is a long period compared with that of an oscillation such as I mean, bearing the same sort of ratio to it as a quarter of a century bears to an hour.

19. A direct experimental proof that lightning is oscillatory will be obtained when photographs of it are taken on a sensitive plate revolving 1,000 times a second. Something short of that speed would cause the image of the flash to blur, but that speed might be sufficient to analyse out the oscillations, when examined carefully with a magnifier, the focussing being good.

Till then the easiest proof that it is oscillatory is a theoretical one, and it can be put in a few words.

20. Consider an air condenser with two coatings, each of area A, separated by the distance h, and let it burst its dielectric. It is well known that the discharge is oscillatory when the whole resistance met with by the discharge is anything less than a critical value.

$$R_0 = 2\sqrt{\left(\frac{L}{S}\right)}.$$

Now, attending only to the straight part of the discharge, and ignoring the current rushing up in the plates to the spark path, the self-induction of a straight conductor of length h and sectional radius a is very approximately

$$L = 2\mu h \log \frac{4h}{a}.$$

The capacity of the discharged condenser is

$$S = \frac{K A}{4\pi h}.$$

Hence the critical resistance which must not be exceeded is given by

$$R_0^2 = \frac{32\pi\mu h^2}{K A} \log \frac{4h}{a};$$

or

$$R_0 = 10\mu h \text{ "r"} \sqrt{\left(\frac{1}{A} \log \frac{4h}{a}\right)}$$

$$= 300 \text{ ohms} \times \sqrt{\left(\frac{1}{A} \log \frac{4h}{a}\right)} \times h.$$

The important thing to notice in this value of $\sqrt{\frac{L}{S}}$ is that it is approximately proportional to the first power of h, the distance between the plates of the condenser.

21. Next consider the resistance of the discharge path. It too will be proportional to the length h, and it may be written

$$R_1 h,$$

where R_1 is the resistance per unit length of the discharge path.

The condition for oscillation, then, is that this $R_1 h$ shall be less than R_0 : or *the resistance of unit length of the spark must be less than*

$$300 \text{ ohms} \times \sqrt{\left(\frac{1}{A} \log \frac{4h}{a}\right)}.$$

22. The term under the square root will take different values according to circumstances, and it may be greater or less than 1 per metre. Ordinarily, however, it will be greater than 1 per metre, unless the area of charged surface is considerable. The important thing is the way in which h, the distance between the plates, enters into the expression. It does not come in very prominently at all, but so far as it does influence the result it permits the discharge to be oscillatory more easily when the plates are a good distance apart than when they are close together.

23. Take a couple of typical examples. First, a Leyden jar bursting its glass. A fine needle may be just put through the hole usually made in these cases, so we can take the sectional radius a as something like a tenth of a millimetre. The thickness of the glass may be 2 millimetres, hence $4h/a = 80$ or thereabouts ; and the natural logarithm of this is about 4. Suppose the area of coated surface is half a metre square, then the critical resistance which a metre of the spark must not exceed is 1,200 ohms, and so the 2 millimetres of it must not exceed 2·4 ohms.

It is difficult to say whether this is or is not a large resistance for such a short spark, and hence it is difficult to be sure that such a spark is anything more than a mere one-directional discharge. To go into it more fully the currents in the metal coatings would have to be considered. Next take as example a cloud area at an elevation of one kilometre ; and because a lightning discharge usually makes perforations of fair diameter, we may suppose a to be about a millimetre. (A widely erroneous estimate in this quantity makes but little difference in the result.) In such a case $4h/a = 4 \times 10^6$, and the logarithm of it is between 15 and 16. Hence the charged area may be 15 or 16 square metres without bringing down the square root term below 1 per metre ; so the resistance of the whole flash may in that case be anything below 300,000 ohms without checking the oscillations. The discharged area may indeed be as much as 1,500 square metres without bringing the critical resistance which the flash must not exceed below 30,000 ohms, or 30 ohms per metre. (Understand that "resistance" here does not mean impedance. It means true dissipation of energy resistance (sec. 25), and the current squared is so enormous (sec. 29) that the resistance-coefficient may be quite small).

In another place (*Phil. Mag.*, August, 1888) I have shown reason for believing that the area of cloud discharged at any one flash is usually very moderate ; and hence on the whole I consider it proved, so far as elementary theory can do it, that the lightning flash usually takes place under conditions favourable to oscillation.

24. And these oscillations are extremely rapid. The rapidity depends on the inverse geometric mean of L and S, and this is practically almost independent of h. Referring back to their values we see that

$$LS = \frac{\mu K A}{2\pi} \log \frac{4h}{a};$$

and so the number of complete alternations per second is

$$\text{"}v\text{"} \sqrt{\left(2\pi A \log \frac{4h}{a}\right)},$$

which, in the second example of Section 23, with A as 100 square metres, becomes

3 millions per second.

If the discharged area were as great as 10,000 square metres the rate of alternation would still be a third of a million per second.

(To be continued.)

SECONDARY BATTERIES.*

BY WILLIAM HENRY PREECE, F.R.S.

Secondary batteries are often called accumulators and storage batteries, and the general impression is that they accumulate or store that which is called "electricity." What is accumulated or stored is, however, energy in its chemical form. A *secondary* battery is really a battery pure and simple, but it differs from a *primary* battery in this, that the chemical character of the conductors or plates and the electrolyte in which they are immersed has been excited by an electric current which has passed through them continuously for some time, while in a primary battery the chemical affinities exist in the materials of which the cell is composed. In the language of the distinguished American, Judge Coxe, "A secondary battery is one which gives no electricity of itself, but is active only when rendered so by a current from an independent source."

Secondary batteries have become an essential feature of every properly equipped isolated electric light installation, not only for the regulation of electric currents and the maintenance of uniform electromotive force, but to give a store of energy to draw upon at night and when any accident or failure occurs. They are also employed for the distribution of electrical energy from central stations. They are used for ship and for train lighting, and they seem destined to solve the important question of economical traction on our tramways. They are much used in telegraphy. They have passed through a very severe ordeal of seven years' practical development in the face of determined opposition and in spite of the prejudice resulting from disastrous commercial speculations and from the non-fulfilment of over-sanguine hopes and hasty utilitarian anticipations.

The father of lead secondary batteries, in a scientific sense, is the eminent French electrician, Gaston Planté, but the final stroke that made the apparatus a real practical instrument was the discovery of Faure, who showed that the application of oxides of lead,

* Paper read before the Society of Arts, May 1, 1889. This subject has been before the society on two occasions. In 1881 (vol. XXX., p. 30) Prof. Silvanus Thompson read a Paper on the "Storage of Electricity," and in 1883 (vol. XXXI., pp. 1025, 1038), Prof. Oliver Lodge, F.R.S., gave two lectures on "Secondary Batteries."

Digitized by Google

in the form of a paste or cement on the surface of the lead supports, so hastened the process of formation of the plates that the battery was made a commercial and valuable instrument. Sellon, Volkmar, Swan, Julien, Parker, King, Drake and Gorham have added so much to the mechanical details, and have done so much to remedy defects and remove faults of construction, that all we want now is to crystallise into practical language the teachings of experience.

My house has been lighted by these batteries since March, 1884, now five years ago. I commenced with seventeen Planté cells, manufactured by Elwell, Parker and Co., of Wolverhampton, charged by currents from a dynamo driven by a 2 horse-power gas-engine, but after two years of experimenting I selected twenty-six cells of the 15L E.P.S. type, with which form of cells I am now working. Their value can be illustrated by the following fact :—On March 30 my gas-engine broke down. I qulte forgot to give notice to the makers to send down men to repair it until six days had elapsed. It took five more days to repair the engine, so that for eleven days I had not been able to re-charge the cells ; but during all these days the light never failed, and we were not in any way inconvenienced. The useful capacity of my cells is 330 ampere-hours, and my nightly consumption is now about 30 ampere-hours. This was a very good test of the efficiency of the cells, for I obtained from them nearly all the energy they could usefully give. Only two cells were really exhausted during this time, but as I had two spare cells to replace them, their exhaustion did not cause me any inconvenience. The E.M.F. fell to 1·8 per cell, and the light in consequence was not so brilliant as usual. A good practical test of the efficiency of a battery like this is better than any isolated tests on single cells.

The illumination of this hall (Society of Arts) is regulated by 58 E.P.S. cells, of 13L type, an obsolete form, which are used, when the hall is not open, to light the secretary's and the public offices. They have been at work here since January, 1885, and have given no trouble and very great satisfaction.

Types of Cell.

There are several kinds and types of cells in use at the present day, but the principal ones supplied in England are by the Electrical Power Storage Company and by Elwell-Parker Company (Limited). The E.P.S. cells are of several patterns :—

"L"—Stationary cells used for electric lighting, motive power, and general purposes.

"T"—Portable cells used for tram-car and launch propulsion.

"C"—Portable cells for railway-carriage lighting.

Of the "L" pattern the following are the sizes issued :—

No. of plates.	Weight.	Maximum rate of discharge (amperes).	No. of 10 candle-power lamps. (26 cells).	Capacity (ampere-hours).
	lbs.			
7 L	68	13	21	130
11 L	101	22	36	220
15 L	128	30	50	330
23 L	211	47	76	500
31 L	265	64	100	660

There is always one more negative plate than positive.

E.P.S. Type, 1888.

The plates of each cell are divided into the positive and the negative, in each case a pure lead grid being cast for retaining the paste-oxide $8\frac{1}{2} \times 9\frac{1}{8} \times \frac{3}{16}$ thick, and weighing 5lb. The perforations or openings of the positive plate are filled with minium, while those of the negative plates are filled with litharge. The plates so prepared are then subjected to powerful currents for several hours, when the litharge (PbO) is reduced to spongy lead (Pb), and the minium and red-lead (Pb_3O_4) become lead peroxide (PbO_2). There is thus economy in reducing the lower oxide and in peroxidising the higher one. Many attempts have been made to manufacture the grids of inoxidisable alloys, such as an alloy of antimony and lead, to which mercury is sometimes added, but so far nothing seems to be superior to the pure lead itself. The principal defect has been that of buckling or deforming, and this is supposed to be due to irregular oxidisation, but no clear explanation has yet been given of the remarkable way in which lead plates curl and curve under the influence of electrolysis. Plates do not buckle when they are properly treated. It is the rough handling of cells—calling upon them to do more than they were designed for, neglecting to maintain the level of the liquid and its density—that principally lead to deformation, disintegration, and also short circuiting from the paste falling out in plugs and resting across the plates. The plates are now fixed $\frac{3}{8}$ths of an inch apart, a sufficient distance to allow any pellet that may fall out to drop harmlessly to the bottom of the cell. This distance can be increased with advantage.

The pellets of paste are now made considerably smaller than was the case at first, and this has been done to hasten the period of formation, and to render the whole of the pellet active, which was not always the case with the larger pellet, for their centres were often found unformed, and therefore idle.

The negative plates of each cell rest on toes or blocks, and are maintained $1\frac{1}{2}$ inches clear of the bottom of the cell, and they suspend the positive plates by lead bars running along each side of the negative section, on which ebonite supports carry the positives. All the plates of each kind of each cell are welded or burnt on to a broad lead strip, to which either a terminal is attached, or which is burnt on to the strip of the next cell.

The "L" cells, for fixed permanent installations, are of glass, but for ship, tram, and train purposes they are generally fixed in wooden boxes, rendered water-tight by lead, marine glue, or ebonite linings. Glass is much preferable to wood, or to any opaque substance, for it is very useful to see how the plates and their packing are behaving. Elwell-Parker introduced a cell made of an inoxidisable alloy, but it has not been received with favour.

Glass has this advantage, that it is an excellent insulator, though owing to its hygroscopic tendency it has been found necessary in some cases to mount the cells on oil cups—a plan that is always necessary with wood and metal boxes.

The electrical leakage from glass cells when the acid spray is checked is very small indeed. They retain their charge unimpaired for months. It is, however, a good plan to paint the glass over with paraffin or vaseline occasionally. It checks leakage and prevents the acid from creeping.

Elwell-Parker Cell.

The form of cell supplied by Elwell-Parker differs in several details from the E.P.S. pattern, though it is of the same type. The plates are held together by side frames of wood or vulcanite at the edges so as to knit them together very firmly and prevent buckling. The whole frame of the largest size can be lifted in and out by a crane with ease. The negative plates are made in a way which prevents blistering, a defect in the E.P.S. plates, and the grids are burred in a way which prevents the pellets from dropping out. This process, due to Messrs. Drake and Gorham, is an important improvement.

Capacity.

The capacity of a cell is the amount of energy it will accumulate and usefully restore. It is measured roughly either in ampere-hours or in watt-hours. The latter is the more accurate if the fall of E.M.F. is carefully noted, but if the E.M.F. is maintained fairly constant by not running the cells too low, the former is equally practical and more common, The average type of cell, such as the stationary E.P.S. pattern, gives a useful capacity of 4 ampere-hours per lb. of plates complete. I have had a cell (Fitzgerald's lithanode) which gave a return as high as 5·7 ampere-hours per lb., while the Planté type rarely exceed 2 ampere-hours per lb. The portable form used for traction purposes gives 5 ampere-hours per lb., but this is only because the plates are much lighter.

Efficiency.

The efficiency of a cell is the ratio between the energy taken out of it to the energy put into it, and the useful efficiency is usually taken from the number of ampere-hours discharged when the E.M.F. falls 10 per cent. in magnitude, This figure is a very variable quantity, for it depends very much on the current density ; that is, upon the number of amperes per unit of surface—one square centimetre—of plate. The following experiment on a small cell illustrates this point :—

Current density.	Ampere-hours.
·013	44·6
·048	36·5
·09	30·2

The ordinary current density, which should not be exceeded in practice, is ·01. This means that the maximum output should not exceed 4 amperes per positive plate.

A cell will discharge many more ampere-hours than are given by this useful efficiency, and if the discharge be taken with a very small density the efficiency may reach a very high figure. Thus 95 and 98 per cent. have been obtained from small cells slowly discharged. The efficiency of a cell therefore varies with its rate of discharge. If the efficiency with an output of 5 amperes be 90 per cent., it will be only 50 per cent. with a discharge of 40 amperes. Batteries drop in E.M.F. if the rate of discharge is high or the current density great. They should, therefore, be discharged at a slow rate. The most general maximum rate is found to be that which discharges a cell in ten hours. Thus the discharge of 15 L cells should not exceed 30 amperes, nor that of 31 L cells 60 amperes.

It is sometimes thought that because the E.M.F. in charging is 25 per cent. greater than in discharging, there must be a loss of energy to that amount, but the fact is this loss of E.M.F. is compensated for by gain of current, owing to the reduction in the internal resistance of the cell. The internal resistance of a cell, which is normally about ·0003Ω per positive plate, diminishes with the strength

Digitized by Google

of the current of discharge, and therefore it is possible to get nearly all of the energy out of a cell that has been put into it. The efficiency of a secondary battery increases with the lightness of the load put upon it, and in this respect it possesses a great advantage over that other transformer of electric energy, namely, the secondary generator of Gaulard.

It has been the practice to place the plates in a cell very much too close to each other. This not only favours short circuiting, but it prevents the free circulation of the electrolyte. Recent experiments have also shown that efficiency has also been improved by increasing the distance between the plates.

The Electrolyte.

The character and the quality of the electrolyte used in secondary cells has scarcely received the attention it deserves. Hitherto scarcely anything but a solution of sulphuric acid has been employed. Experience seems to show that the best solution to use before charging is one which has a density of 1·150. Such a solution in a 15 L cell, when fully charged, will acquire a density of from 1·210 to 1·220, and it is customary to maintain the density of the cells somewhat between 1·170 and the higher figure. One of the great troubles with secondary cells that are imperfectly and improperly treated is the formation of the white sulphate of lead that is frequently seen upon both plates. In fact, it is the root of nearly all the ills that these cells are heir to. There are many ways of getting rid of this sulphating. The plan used by Mr. Sayers, the engineer in charge of the St. Pancras Hotel installation, is described by him as follows :—

"Our battery of 120 15 L cells was rather badly covered with sulphate of lead. At first I simply charged them with the ordinary maximum charging current, 30 amperes, when each cell on becoming full would give about 2·5 volts. The sulphate, however, did not apparently move. I then tried charging with 40 or 45 amperes for a few weeks, and the change in the look of the plates—of the peroxide plate chiefly—was considerable. They began to exhibit patches of the well-known plum-coloured peroxide, and nearly all had the appearance of a peroxide plate covered with a lace-work of sulphate of lead. This lace-work, also, soon nearly entirely disappeared, and the majority of the plates are now looking very well. The E.M.F. of each cell, with 40 amperes charging current, is about 2·7 volts when the cell is milky. I have thought that this result was due either to the fact—if it is a fact—that sulphate of lead requires more than 2·5 volts to decompose it thoroughly—say 2·6 volts—or that the large quantities of nascent hydrogen attack the sulphate and combine, making sulphuric acid and lead."

It occurred, however, in 1886, to Mr. Barber-Starkey, of Aldenham-park, near Bridgnorth, to see if carbonate of soda in the presence of lead had any beneficial effect upon plates liable to sulphating. The result was very satisfactory; all traces of sulphating disappeared. He treated his own cells in this way, and the effect was so decidedly advantageous to all appearances that I determined, after careful inspection and inquiry, to make an exhaustive experiment that should determinethe question, and at the same time settle the best proportion to use. Six new 15 L cells of the Elwell-Parker make were taken, and they were charged with solutions in the following manner :—

No.	Sulphuric acid.	Sulphate of sodium.	Water.
1.	5 pints.	5 pints.	15 pints.
2.	5 ,,	4 ,,	16 ,,
3.	5 ,,	3 ,,	17 ,,
4.	5 ,,	2 ,,	18 ,,
5.	5 ,,	1 ,,	19 ,,
6.	5 ,,	—	20 ,,

The sulphate of sodium solution was prepared by first making a saturated solution of carbonate of soda (ordinary washing soda), and then adding thereto sulphuric acid until effervescence ceased. The cells so prepared have been charged and discharged, and watched with great care from May 1st, 1888, until the present day. We, therefore, have exactly twelve months' experience of their behaviour, and there can be no doubt as to the beneficial result. The solution marked No. 5 is that which has given the best results, and after about six months' experience of its behaviour two complete sets of 52 No. 23 L cells were charged, the one with the ordinary sulphuric acid solution of 1·175 density and the other with sulphate of sodium solution of 1·225 density. Six months' experience of these two sets has confirmed the result that immense benefit is to be derived from the sulphate of sodium solution. There has been no evidence of buckling, there has been little or no scaling. The bottom of the cells are nearly as clean as when they were first discharged, while the bottom of those charged with the sulphuric acid solutions have the usual accumulation of oxides of lead. Two cells were also and at the same time charged, the one with the sulphuric acid and the other with the sodium solution, and very careful tests of these two cells show that the addition of soda does not impair either the E.M.F. or the internal resistance, nor does it diminish the output of the cells. I have, therefore, come to the conclusion that the addition of soda has a distinct beneficial result, and it is my intention to use it invariably in future. The cells so provided remain in splendid condition. They can be left for months without developing any trace of sulphating or even of loss of charge. Carbonate of soda thrown into a badly-sulphated cell unquestionably leads to the rapid removal of the sulphate of lead, and this is supposed to be due to the fact that a carbonate of lead is formed which is easily reduced and always produces beautiful deep puce-coloured peroxide of lead.

Mr. R. Davids writes, January 18, 1889, to me from Campinas, Brazil :—"As might have been expected, the cells (which had been delayed in transit) were very badly sulphated, but after 24 hours' charging I gave them a dose of soda, which proved a *santo remedio*."

The electrolyte that I recommend for adoption is this :—To a quart of saturated carbonate of soda solution add slowly, during continuous agitation, 12 fluid ounces of strong sulphuric acid ; fill the cell with water 19 parts, strong sulphuric acid 5 parts, soda solution 1 part ; total, 25 parts. The specific gravity of this electrolyte should be 1·210.

It is a mistake to use cells of too small a capacity for stationary purposes. This is usually done for economical reasons, owing to the capital expenditure involved in purchasing cells. Twenty-six 15 L cells cost £78, and the same number of 23 L cells cost £117, but I believe it to be true economy to expend the additional £39. Greater efficiency is obtained out of the larger cells now that soda has prevented injurious sulphating, for you are not limited to a minimum current as you are with the sulphuric acid solution. Small charging and discharging currents mean not only greater efficiency but greater durability of the plates. Secondary batteries used for telegraphy show no sign of disintegration. It is overtaxing cells that destroys the plates. Mr. Barber-Starkey's cells at Aldenham Park have now been in use for three years, and to all appearances they are quite as perfect now as when first set up.

Maintenance.

The chief secret of the successful working of a set of secondary cells is careful and regular attention to their behaviour, and the immediate remedy of any defect that may develop. They require daily testing and inspection. My battery is tested every morning for E.M.F. by means of a Cardew's voltmeter. If the total number of volts divided by the number of cells is not over 2 per cent., each cell is tested separately by a portable Walsall voltmeter, graduated to tenths of a volt, until the defective cell is found. This has very rarely happened—in fact, only once during during the past twelve months, when a plugging fell out, rested between the two plates, and short-circuited the cell.

Six cells are also tested every morning for density by a hydrometer, which is recorded in a book. The six cells are changed every month, so that each cell of the battery passes through this ordeal three times a year. The regular rise and fall of the specific gravity of a cell is the very best criterion one can have of its good working. I cannot do better than transcribe the record of one week's testing.

* The density of the cells requires to be equalised periodically.

The normal density when the cells are charged should be 1·220. They fall 1 for every 5 ampere-hours taken out, and when they reach 1·150 they are exhausted. The density is thus a record of the energy that has been taken out, and of that which remains in.

Occasionally I test them for internal resistance (ρ), both when charging and discharging. In the latter case the discharge current into the house is regulated by lamps to give 10 amperes when the E.M.F. (E_1) at the terminals is read. The E.M.F., when the ends are free (E_2), is also read. Then—

$$\frac{E_2 - E_1}{10} = \rho$$

Digitized by Google

I make the current 10 for the internal resistance varies with the current,* and by always using the same current I have an accurate comparison. The internal resistance of my 15 L cells is usually ·0012 ohm. per cell when discharging, and ·005 when being charged.

When a cell becomes defective by short circuiting or any other cause, the plates are taken out, their faces scraped and straightened, the solution cleared, and the cell thoroughly cleaned. The cell is always benefited by such a process, for the cleaned cell is always the first to come up to the charge by as much as 1½ hour.

The cells in this building have been very carefully tended during the four years they have been at work. Only three sets of positive plates have been renewed.

In charging cells, there are three distinct indications that the cell is fully charged :—

1. The E.M.F. suddenly rises up to 2·5 volts per cell.
2. The hydrometer indicates 1·220.
3. The electrolyte becomes milky by the fine bubbles of gas that float in the disturbed solution during their gradual ascent to the surface and escape into the air.

The rise of bubbles of gas to the surface and their bursting scattered a considerable amount of acid spray about in the battery room, which was injurious to metals and apparatus ; but Mr. F. Higgins, Memb.I.E.E., showed how to prevent this by covering the cell with a fine net or with calico. Glass plates are now much used instead of calico, but I have adopted Mr. Henry Edmunds' plan of pouring upon the surface of the solution melted paraffin, which solidifies and coats the surface with a uniform thin layer of what looks like ice.

It is necessary to be cautious in approaching cells with naked lights when they are being charged. There are several instances of explosion and injury to person in consequence.

The chief defect of the negative plate is that the plugging scales and falls off in thin flakes. This, in the recent types, falls harmlessly to the bottom, but it should not happen at all, and it is due either to imperfect material or to hasty formation. The negative plate should certainly last for ten years. The positive plates also disintegrate, and to a much greater extent. The disintegration of the lead peroxide seems to be a necessary consequence of the action of the cell. It varies with the rate of discharge. If the cells be worked heavily it occurs rapidly, but if the maximum rate of the output of about four amperes per plate be adhered to, the duration of the plate may be taken to be three years. The decay of the positive plate seems to occur almost entirely in the lower half of the plate, and this is probably due to the greater density of the solution favouring unequal distribution of current.

Central Stations.

The secondary battery lends itself admirably under certain circumstances to the economical distribution of electric currents from central stations. It is possible to lay down a long main circuit of small dimensions, conveying a direct current of high E.M.F. which at different points can charge a secondary battery of a small number of cells, so as to "transform" the dangerously high E.M.F. into one of a low and harmless character in the building to be illuminated ; in fact, this is now being done in Chelsea by two different companies. The one company, the Chelsea Electricity Supply Company, is acting under the statutory powers of a Provisional Order, and it distributes its currents to the houses from sub-stations, where the batteries are kept and maintain a continuous supply of electric energy. Each sub-station, of which there are three, supplies current for 2,000 30-watt 10 candle-power lamps. There are 265 31 L cells, divided in two sets of groups of 53. Each set is charged separately and alternately in series from the central generating station. While one set is being charged the other is supplying currents to the consumer. The main charging current of 60 amperes has an E.M.F. of 500 volts per distributing station, or 1,500 volts for the present circuit ; and the secondary discharging supply into the houses has a pressure of 100 volts. This system of distributing currents from batteries has many advantages. The currents being direct are available at once for motor purposes, as well as for lighting. The currents being so steady and uniform add to the durability and life of the lamps. The supply being continuous day and night, it is always available, just as is the light from gas. The distributed currents being of low E.M.F., absolute safety to person is secured in such a system. The engines at the central station, being always worked at full loads, can be worked under their most economical conditions, and as they cay be worked continuously throughout the twenty-four hours, a minimum capital expenditure in engine plant is necessary. It has already been pointed out that the efficiency of the battery is not much affected by variations of its own load, and that whether one lamp or 100 lamps be used it is of not much consequence to the cells ; in fact, the efficiency of the lighter load is the highest. On the other hand, it must be pointed out that there is a considerable capital outlay required in batteries. The depreciation of the cells is very considerable, and there is an appreciable loss of energy at each transforming point. The maximum efficiency of batteries in practice rarely reaches 70 per cent., while less than 15 per cent. for depreciation can scarcely be allowed with prudence. The batteries for 1,000 lamps cost £1,325, or 27s. per lamp. The reliability, constancy, and permanence of the light from batteries compensates for many another evil. The other company in Chelsea—the Cadogan Electric Supply Company—places the batteries in the houses, and charges 1,000 E.P.S. 31 L cells over a circuit of nine miles.

There is a central station in Detroit, in the U.S.A., also distributing by batteries, and giving great satisfaction.

The Kensington-court Central Station, established by Messrs. Crompton and Co., and that at Whitehall-court, also use secondary batteries, but the batteries are in the stations and not in the houses. They are used more for regulation and for reserve force purposes than for distribution.

There is also a large central station at Vienna, and one at Darmstadt of the same character.

An extremely ingenious mode of distribution has been proposed by Mr. Henry Edmunds. The battery is divided into four groups. Three groups are jointed in series, and supply energy to the house, while the fourth group is in the main being charged. These groups constantly and continuously change places every three minutes by means of an automatic switch. A third of the battery is, therefore, always being charged, and this means that only one-third engine-power is needed at the central station, and only one-third of the E.M.F. on the changing main. Mr. Edmunds' automatic distributor is an extremely ingenious apparatus, but it has not yet received the test of practical trial, though the sooner it does so the better.

Mr. Preece concluded his Paper with a few remarks upon the application of secondary batteries to electric traction, portable lamps and telegraphy.

* Preece, *Proc.* Roy. Soc., May 6, 1885.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, May 3rd.

Institution of Mechanical Engineers.

2:30 p.m. Ordinary General Meeting. "Description of an Apparatus for Drying in Vacuum." By Emil Passburg, of Breslau.

Society of Arts.

8 p.m. Indian Section. "The Karun as a Trade Route." By Major-Gen. Sir R. Murdoch Smith, K.C.M.G.

Royal Institution.

9 p.m. Evening Discourse. "Aluminium." By Sir Henry Roscoe, F.R.S.

SATURDAY, May 4th.

Royal Institution.

3 p.m. Afternoon Lecture. "The Origin and Development of Opera in England (with Musical Illustrations)." By Joseph Bennett.

MONDAY, May 6th.

Royal Institution.

5 p.m. General Monthly Meeting.

Society of Engineers.

7:30 p.m. Ordinary Meeting at the Town Hall, Westminster. "Recent Developments in High Explosives." By Perry F. Nursey.

Society of Arts.

8 p.m. Cantor Lecture VI., I. "Heat Engines other than Steam." By H. Graham Harris, M.I.C.E.

TUESDAY, May 7th.

Royal Institution.

3 p.m. Afternoon Lecture. "The Italian Renaissance Painters: Their Education." By Jean Paul Richter, Ph.D.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. "The Treatment of Steel by Hydraulic Pressure, and the Plant Employed for the Purpose." By W. H. Greenwood, M.I.C.E. At this meeting the monthly ballot for members will be taken.

WEDNESDAY, May 8th.

City and Guilds of London Institute Old Students' Association.

7:45 p.m. Ordinary General Meeting at the Finsbury Technical College. "The Construction and Maintenance of Secondary Batteries." By J. Appleton, Member.

Society of Arts.

8 p.m. Ordinary Meeting. "Origin and Manufacture of Playing Cards." By George Clulow, F.R.G.S.

THURSDAY, May 9th.

Royal Institution.

3 p.m. Afternoon Lecture. "The Science of Animal Locomotion in its Relation to Design in Art (Illustrated by the Zoopraxiscope)." By Eadweard Muybridge.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting. Discussion on Dr. Lodge's Paper on "Lightning, Lightning Conductors and Lightning Protectors."

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny. Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xi.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo. Cloth Boards, 3s. 6d., post free 4s. (Great Britain).

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1888, and now consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

THE DIRECTORY for 1889 is NOW READY,

And the issue for 1890, which will be still further enlarged and improved, is in preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded to the Publishing Office, 1, Salisbury-court, Fleet-street, London, E.C.

Volume XXII. of "THE ELECTRICIAN."

This week's issue completes Volume XXII. of "THE ELECTRICIAN." Bound Volumes will be ready for delivery on the 13th inst.,

Price 12/6, post free, 13/6.

Cases for Binding Volume XXII. are NOW READY,

Price 2/0, post free, 2/3.

Publishing Offices: 1, SALISBURY COURT, FLEET STREET, LONDON, E.C. And at Manchester, Liverpool, and Glasgow.

"THE ELECTRICIAN" *can also be obtained of the* W. J. JOHNSTON COMPANY (LIMITED), "THE ELECTRICAL WORLD" *Office, Potter Building, New York, U.S.A.*

SPECIAL NOTICE.

With "THE ELECTRICIAN" *for May 17th will be issued a Steel Plate Portrait of the late* MR. C. H. B. PATEY, C.B, *Secretary for Postal Telegraphs.*

A limited number of copies will be mounted on India Paper, and for these early application must be made.

Neat Frames and Mounts can be obtained on application to the Publisher.

UNDERGROUND CONDUITS.

So much has been written and said about the dangers of overhead wires that it is perhaps with a slight sense of relief that we now begin to hear something of the dangers of placing them underground. At all events this may very naturally be the feelings evoked in New York, where partisanship extends to almost every relation of life, and where the advocates of opposing systems of wiring are ticketed "overhead men" and "underground men" respectively. Both of these parties have lately been enjoying lively times, the underground men doing great execution with the axe and chopper, the overhead men with explosive gases. The battle is not yet over, and it is hard to say which will get the best of it; but already it is plain to be seen that neither party will be completely victorious. Neither overhead wires nor underground wires, as such, are in themselves dangerous or objectionable, the risk and offence being due solely to attending circumstances. In certain large cities of the United States, however, notably in New York, the

Digitized by Google

attending circumstances are peculiarly inimical to both systems, owing on the one hand to overcrowded and chaotic erections overhead, and on the other to the gas-laden and steam-saturated condition of the soil underneath. Just at present we in this country are able to say that those conditions do not prevail with us. But we cannot be quite sure of being always or wholly exempt from them; and at any rate there is something to be learnt from the state of affairs which has recently been disclosed in New York, and which therefore it may be well to take note of.

For a long time past the "overhead men" have with a few exceptions deliberately ignored the edict which had bidden them take all their wires underground. The Board of Electrical Control had caused to be constructed several miles of conduit, consisting, as our readers may recollect, of iron piping embedded in concrete. But the companies have hitherto shown very little alacrity in availing themselves of its use. The experience of the Western Union Company, which was the first to attempt to obey the law, was not of a character to encourage the others, since in the "down town" district its wires were saturated with hot steam and the insulation ruined. Meanwhile gas explosions of a more or less serious character occurred from time to time in various portions of the conduit. The recent Presidential election, however, brought a fresh man—presumably from "underground"—to the head of the New York municipality. The new Mayor, prompted by the Board which, in the language of our New York correspondent, "lives and moves and draws its salary" on the strength of its regulations, at once took vigorous action to enforce them, a brigade of ruthless mercenaries issuing forth armed with pickaxes and choppers, the upshot of whose onslaught was that many miles of overhead wires—telegraphic, telephonic, and electric lighting—lay prone on the ground, if not underneath it. One result of this proceeding was that the streets were left in partial darkness, gas lighting taking the place of electric, to the great discomfort of the inhabitants. Another result appears to have been that the underground conduit manholes became more turbulent than ever. Perhaps this was to be expected in a city where making a policeman to "move on," or a telegraph messenger to mend his pace by explosions into mid-air, afford only material for cynical humour. But they have their serious side no doubt to the victims, and in England certainly these playful vagaries of underground conduits will not be treated as a joke.

That the Board of Electrical Control in New York has treated the incidents seriously arises probably from the necessity of defending the conduit system, which so far as the Board's inquiry has gone is proved to be faultless in every particular save one—namely, that it is ill-adapted to the condition of the soil in which it is laid. This to ordinary onlookers would seem fatal, but not so to the Board. The fault lies with the gas companies and the steam-heating supply companies, whose liberality is so unbounded that the subsoil in which their pipes are laid absorbs nearly as much gas and steam as are supplied to the customers overhead. So thoroughly is the soil on which some parts of New York are built saturated with vagrant gas that speculation is said to be on the move to utilise the earth as a natural reservoir for the purpose of lighting the thoroughfares. Certain it is that the manholes ever since their construction have become so many receptacles for infiltrated gas, which combining with the air contained in them has produced an explosive mixture ready to be discharged on the smallest provocation. The question here arises, Whence comes the provocation?—in other words, the ignition?

This question is not easily answered, but as it is one that probably will be often asked, some attempt at a solution of the enigma should be made. The manholes are water-tight, if not air-tight, and perhaps only an underground man would suggest that the gas can be exploded by malice or accident from without. Overhead men of course fix the blame within, attributing the ignition to an electric spark, or to atmospheric conditions which may possibly favour an explosion. Of these atmospheric phenomena we can only say that although highly conjectural they ought to be either refuted or substantiated. The electric spark is more intelligible, and Mr. VERITY, in his recent Paper at the Institute of Electrical Engineers, speaks of cases where "pinholes" have been made in electric cables by disruptive discharges between the conductor and the exterior covering of lead. The genesis of such discharges is not easy to account for, even on Mr. Acheson's "condenser" theory.

In regard, however, to the origin of the inflammable gas—which may not always be coal gas—our attention has been drawn to the account of an incident which occurred in 1879 when the Kampi Cable House, near Banjowangie, Java, was connected with the Eastern Extension Telegraph Company's Singapore cable, which landed about thirteen miles away. The wires were drawn through a two-inch gas piping, which had to be kept filled with water. The narrative goes on to say: "Not many weeks had elapsed when we became aware of the presence of enormous quantities of gas which issued with explosive force whenever one of the vents was opened. One day when Mr. RENTZSCH was standing by one of the vents from which this gas was issuing, he said, 'I wonder whether it will burn?' and suiting the action to the word, applied a lighted match to the vent. With a bang a flame shot up six feet high, singeing his hair and whiskers. The gas, I believe," says the writer, "is carburetted hydrogen, generated by the decomposition of the tape with which the wires were covered as a protection whilst drawing them into the pipe." It was found that the only way of preventing this accumulation of gas was to keep up a continual flow of water through the tube. We regret that our informant does not exactly describe the "tape" covering, but its character can easily be conjectured. The moral of the story, however, lies in the two facts—first, that there was no gas company within a thousand miles of Kampi, and secondly, that the point of danger there, as at New York, was the vent-hole. At Kampi, however, we have the man with a lighted match to explain the ignition, whereas at New York neither man nor match has yet been discovered.

THE BOARD OF TRADE INQUIRY ON THE LONDON ELECTRIC LIGHTING PROVISIONAL ORDERS.

This Inquiry has been continued at the Westminster Town Hall since our last report. The following gentlemen represented the various parties concerned:—

Mr. Pember, Q.C., Mr. A. K. Loyd, and Mr. J. C. Graham appeared for the London Electric Supply Corporation; Mr. C. A. Cripps for the Metropolitan Electric Supply Company; Mr. Moulton, Q.C., and Mr. R. S. Wright for the Chelsea Electricity Supply Company; Mr. Muirhead for the St. James's and Pall Mall Electric Light Company; Mr. Roger W. Wallace for the Notting Hill Electric Light Company, for the Kensington and Knightsbridge Electric Lighting Company, and for the Westminster Electri Supply Corporation; Mr. Moulton, Q.C., and Dr. Hunter, M.P., for the Electrical Power Storage Company; Mr. G. Prior Goldney (the City Remembrancer) for the City of London; Mr. T. Percy Gunyon (engineer) and two members of the Council for the London County Council; Mr. C. A. Cripps and Mr. F. M. Jenkins for the Strand District Board of Works; Mr. Hopwood (solicitor) for the Holborn District Board of Works; Mr. E. Bayley (clerk) and Mr. G. W. Thompson (surveyor) for the St. Olave's District Board of Works; Mr. James Spencer for the Greenwich District Board of Works; Mr. J. H. Horton for the Paddington Vestry; Mr. Hitchins for the St. George's (Hanover-square) Vestry; Mr. Wilkins (clerk) and Mr. W. Jenkins (chairman of the Lighting Committee) for the St. James's (Westminster) Vestry; Mr. Webster Murnane (clerk) for the St. Martin's-in-the-Fields Vestry; Mr. T. Eccleston Gibb (clerk), and Prof. Robinson, C.E., for the St. Pancras Vestry; Mr. Cripps and Mr. Greenwell for the Marylebone Vestry; Mr. H. J. Smith (clerk)

Digitized by Google

for the Lambeth Vestry; Mr. Harrison (solicitor) for the Bermondsey Vestry; Mr. E. Moore (solicitor) for the Great Eastern Railway Company; Messrs. Payne, Son and Pollock (solicitors) for the North London Railway Company.

WEDNESDAY, APRIL 24.

Mr. JOSEPH BROWNE MARTIN, examined by Mr. WALLACE, said that he was a director of the Westminster Electric Supply Corporation (Limited). That company's nominal capital was £100,000. All the portions of the City of Westminster had, during the course of the inquiry, been abandoned, with the exception of the parishes of St. Margaret's and St. John the Evangelist, and St. George's, Hanover-square. The capital had been subscribed for the purpose of arranging as to the purchase of sites and the fitting up of a small plant adjoining Victoria-mansions. The latter would cost about £8,000. The directors were Lord Suffield, Sir John Heron Maxwell, Mr. Henry Kimber, M.P., Mr. Hayes Fisher, M.P., and the witness. They had secured three sites for battery stations and were negotiating for two others. Two sites were wharves. Contracts for the erection of plant had been entered into with Messrs. Crompton and Messrs. Latimer Clarke, Muirhead and Co. The parishes of St. Margaret's and St. John's, Westminster, were to be lighted by Messrs. Crompton, and the parish of St. George's, Hanover-square, by Messrs. Latimer Clarke and Co. When the other stations were completed the Victoria-mansions site was intended to be used as an auxiliary. The boilers had been put down, and the dynamos and other machinery were ready for delivery, and it was expected that plant would be erected sufficient to supply 5,000 lights within six weeks, possibly within a month.

Cross-examined by Mr. PEMBER: In the case of this company there were no special patents to sell. From memory he should say there were about 20 shareholders liable to pay up the subscribed capital of £100,000.

Mr. PEMBER applied for a list of the shareholders, and after some discussion,

Mr. WALLACE said that he had no doubt that Mr. Martin would furnish it.

Cross-examination resumed:—The shares were of the nominal amount of £10 each; he held £50,000 worth himself. There was power to increase the £100,000. The £8,000 he had mentioned was for putting up the present installation for 5,000 lights. Messrs. Crompton's contract was for about half of it. The £8,000 did not cover all the contracts, others having been arranged on the basis of so much per light; he should estimate himself that 100,000 lights would cover the lot. They came out to about 35s. per light.

Re-examined by Mr. WALLACE: They did not apply for that portion of St. Margaret's Vestry that was outlying St. Georges's, Hanover-square—that is the Knightsbridge portion. The outlying part of St. Margaret's, and also St. Clements Danes and St. Martin's-in-the-Fields, were abandoned, and the Strand was abandoned.

Mr. LATIMER CLARKE, examined by Mr. WALLACE, said that his firm had erected the St. James's central station. The St. George's, Hanover-square, contract would take about four months to commence giving light from the date of getting the order to proceed, and to complete within six or seven months. They could supply 20,000 lights within four months, and another 20,000 within two months longer.

Cross-examined by Mr. PEMBER: The contract was a provisional one, and the estimates were about 30s. a light, the price not to exceed what was adjudged fair by proper arbitrators.

There is nothing to prevent an arbitrator giving a much higher sum than 35s. a light?—Most obviously. They had advised Mr. Martin that they could do the whole thing for 35s. a 10 candle-power light. His firm were to be paid in money and not in shares.

Cross-examined by Mr. MOULTON: On what system is the supply to be given?—It is the ordinary 3-wire system, assisted by batteries at the out stations.

Re-examined by Mr. WALLACE: If there was anything unfair to either side in the contract arranged, if there was any exceptional work, that was to be settled by arbitration—that was the nature of it.

Mr. PEMBER: He said the absolute price—the contract price—was to be settled by arbitration.

Mr. WALLACE: But there is a maximum given.

Mr. PEMBER: No, he said not distinctly. I asked him.

The WITNESS: Well, we consider ourselves bound by the maximum. In further reply to Mr. PEMBER as to the details, witness said that they had told Mr. Martin that he could erect the whole for 30s., lamps and everything, and they were prepared to do their part of it at a price which would enable him to buy his stations and complete the work at that price.

Major MARINDIN: I understand the arrangement is you have undertaken to supply for 35s.?—We have told him we are willing.

Mr. WALLACE, after some further discussion, undertook to produce the agreement. As to the Westminster portion, Mr. Crompton could be re-called on his return from Berlin if any one wished to cross-examine him. His was an actual contract, and he was actually supplying the plant now.

Mr. KILLINGWORTH HEDGES, examined by Mr. Wallace, said that he had three clients anxious to take the light—the St. Stephen's Club and two shops of the Aërated Bread Company. They would prefer to have it on the direct system with storage batteries, and that was made a *sine qua non* at the St. Stephen's Club.

Mr. FREDERICK WILLIAM ANDERSEN, examined by Mr. WALLACE, said that he was electrician to Messrs. Latimer Clarke, Muirhead and Company. The St. James's station had so far worked satisfactorily; at present there were no batteries. For the St. George's, Hanover-square, district it was proposed to have a battery supply system.

Cross-examined by Mr. GRAHAM: They proposed to use batteries as a stand-by and for regulation purposes. The battery power if called upon would supply 5,000 lights for one hour. They proposed to use E.P.S. cells.

Mr. C. A. CRIPPS said, with reference to the Strand agreement, that the only alteration of substance of any kind met the point raised by the St. Giles's Board of Works. As the agreement stood at present the Strand was to have the primary right to be supplied from Sardinia-street. They had arranged that Sardinia-street should come out of the agreement another station being substituted within the district of the Strand itself The new station was to be in Cecil-street.

Mr. MUIRHEAD was then heard on behalf of the St. James' and Pall Mall Electric Light Company. He said that he objected to the application of the London Electric and also to that of the Metropolitan. His company was started in consequence of the dissatisfaction caused in St. James's by the unsatisfactory lighting from the Grosvenor Gallery. The parish might roughly be divided into two areas—the first to the south of Piccadilly, containing all the clubs and a great many public buildings, which required long hours of lighting; to the north there was the poorer district, where workpeople would require motive power. So the St. James's Company resolved to establish two stations, the station in the southern part to be adapted specially to lighting purposes, and the northern station afterwards was to be established for the purpose of supplying motive power; but in order that it should be of use in a general system the machinery was so designed that when the current was turned off in the northern portion of the parish it should be utilised in the southern to assist the machinery in the south at the time of the maximum supply. A license was granted by the Board of Trade in December last. The St. James's Company did not intend to go beyond the boundary of the parish, and they desired to meet the whole of the requirements of that parish; and, having that object in view, they had accepted all the amendments that were proposed by the vestry. At the time the company was proposed a prospectus was sent out setting forth the objects of the company; and while the subscription list was still open the Grosvenor Gallery Company—he had no doubt to protect their own interests, and to try and prevent the successful floating of the St. James's Company, which was going to be a competitor—issued a map covered all over with red patches to show that the ground was practically occupied. This, however, did not affect the floating of the company. £28,000 was subscribed in the first instance, and the number of shareholders on the list was about 60. The company then purchased the site in Mason's-yard, the cost of which was £9,500. They then spent in the construction of the building £8,500, and entered into a contract for the supply of machinery for 10,000 lights at a cost of £18,500. This contract was divided into two sections, the first for 5,500 lights for £11,000 and the second making up the lights to 10,000 for £7,500. The first portion of the contract was now practically completed, and the company was now about to lay down the first section of mains, the system adopted being the low-tension system, and the machinery being divided in a similar way to that of the Metropolitan Company in Whitehall. The system of distribution was the three-wire, and they proposed to establish a network of mains through every street in the southern half. There would be a ring main running down St. James's-street, along Pall Mall, up Regent-street, and along Piccadilly, and this ring main would be connected by means of feeders with the station. He did not think it would be necessary for him to call any scientific witnesses, as the system was well known, and beyond minor matters of regulation he did not think possessed any novelty.

Mr. EUSTACE BALFOUR, examined by Mr. MUIRHEAD, said he was the chairman of the board of directors of the St. James's Company, and was an architect by profession. His company had acquired the freehold of the site of their first central station in Mason's-yard, the capacity of which is for 35,000 10-candle lights. With accumulators he was informed the total capacity would be 80,000 lights as a maximum. They had actually commenced operations, and had lighted one club with a temporary main very satisfactorily. The system was the three-wire low tension, with an average voltage of about 110. The district was a good one, being full of the best clubs and the houses of a great many rich people, the War Office, large banks, important hotels, one or two large concert halls, and very rich shops—a district where one might expect almost every building to require the light, and in many cases at especially late hours. It was proposed to connect the system of the northern half and southern half of the district, so that a total breakdown would be practically impossible. They had no transformers, but they proposed eventually to use storage batteries.

Cross-examined by Mr. PEMBER: Their nominal capital, subject to increase, was £100,000, of which £28,000 is at present subscribed. His co-directors are Mr. Hemmerde, Mr. Kirby, Colonel Francis, Mr. Royds, and Mr. Latimer Clarke.

Mr. JAMES HEMMERDE, examined by Mr. MUIRHEAD, said he was a director of the St. James's Company. About £10,000 had been paid for the freehold of the site of their station, the building contract £8,000 odd, and the machinery erected and in course of erection cost £11,000. They had deposited £2,000 with the Board of Trade, which is released in sums of £500 as the mains are laid. They had secured further capital in the form of debentures to the extent of £25,000.

Cross-examined by Mr. PEMBER: All the directors, with the exception of Mr. Royds, hold £1,000 worth of shares each. There were about sixty shareholders. He had not got a list of their names with him, but could produce it.

THE CASE OF THE VESTRIES.

Rotherhithe Vestry.

Mr. STOKES, in addressing the Inspector on behalf of the Vestry of Rotherhithe, said the objections of the Vestry of Rotherhithe were very few, and there was really not much opposition to them, if any. The first objection the vestry had was to placing any mains above ground, along, over, or across any street. They thought that overhead wires were dangerous, and should not be sanctioned. In the second place, they thought they were not sufficiently protected in cases of breaking up streets for the

Digitized by Google

laying of mains. They also thought it objectionable that the undertakers should have power to interfere with or alter the position of any pipes already under the street belonging to other companies. They objected, in the last place, to the short notice of forty-eight hours for the commencement of works in the streets, and would suggest that not less than fourteen days' notice should be given. The vestry did not object to the preamble of the order, to the general principle of the order, and they only required protecting clauses with reference to taking up streets, the making of sewers, and most particularly overhead wires.

Mr. GEORGE LEGG, examined by Mr. STOKES, said he had been the Surveyor of the Sewers to the Vestry of Rotherhithe for thirty years. He thought that the clause enabling the company to interfere with or alter the position of any pipes or wires in any street belonging to other companies would be very objectionable. The general surface of the parish of Rotherhithe is much under high-water mark.

Mr. EDWARD THOMAS, Surveyor of Roads to the Vestry of Rotherhithe, was shortly examined on the same point, after which

Paddington Vestry.

Mr. NASH said he proposed very shortly to state the views of the parish of Paddington. He did not propose to deal with the systems of the companies applying for orders over his district, but would adopt without repeating them the arguments of the other counsel who opposed. They had not had evidence of any great demand for the electric light in Paddington, and he thought that was a cogent reason why no power should be given to companies simply to enable them to experiment in the locality at the expense of the inhabitants. In the case of Paddington there was the special objection against the proposed orders that the vestry were anxious to take the lighting of their own area into their own hands. The matter had for some time been under their consideration. Some months ago they instructed Prof. Forbes to consider the question of themselves lighting the area, and they had had a very full report from Prof. Forbes* pointing out the cheapest and most effective way of carrying out the lighting, and also stating the advantages which would accrue to the neighbourhood if the vestry themselves obtained the power. The argument, then, came to this:—That it would be better, having regard to public convenience and the convenience of the neighbourhood and the public in that locality, that powers should be granted not to two companies, not to a single company, but to the authority in the district, which could more cheaply and more effectually, and generally in a better manner, administer to the wants of the neighbourhood. The Inspector might think it well to recommend that some limited time should be given to the vestry within which they should signify their intention to apply for a Provisional Order, and that any powers granted to the companies should be subject to that condition.

Mr. FRANK DETHRIDGE, Vestry Clerk of the Parish of Paddington, examined by Mr. NASH, gave evidence in regard to the wish of the vestry to do their own lighting.

Prof. GEORGE FORBES, examined by Mr. NASH, said that several months ago he was requested by the Paddington Vestry to advise them as to the advisability of their undertaking the electric lighting of their district, and made a report to them on the subject. He thought with underground mains any company starting to supply continuous-current arc lights would certainly have to charge above £30 per light per annum for the number of hours they are used, whereas the vestry could do it themselves for about £20. As to domestic lighting, taking 15,000 16-candle lamps—real 16-candle lamps, not nominal—the cost would come out to 4½d. per Board of Trade unit. The labour under a vestry would be much cheaper, and they would also have no dividends or directors' fees to pay, besides being able to utilise dust-bin refuse for fuel, which would save an expenditure of over £1,000 a year which is at present expended upon getting rid of that refuse. He estimated the capital expenditure of the Vestry on the necessary works would be £95,000 roughly.

Cross-examined by Mr. MOULTON: He was not aware that one of the companies to whom he was consulting engineer was applying at the time he was consulted by the vestry. He did not consider the present furnaces burned dust-bin refuse satisfactorily. He was the first person to start a central station in London—it was in Haydon-street, Regent-street, for the British Electric Light Company in 1882. It was stopped by injunction six months after it started. When he said the cost of street lighting would be £30 to a company and £20 to the vestry he was comparing the regular charges, taking arc lighting on a continuous-current high-tension system. For the £30 he had taken the cost at Taunton and Bath, and added the difference of cost between overhead and underground wires, and it came to £30. The charges for arc lighting are usually made at so much per annum on so many hours' lighting.

Cross-examined by Mr. C. A. CRIPPS: He was not aware that dust-bin refuse had been offered to the Metropolitan Company and £2,000 a year in addition if they would get rid of it. He had not heard there were no furnaces which could deal with it. He did not know until the day before he delivered his report to the vestry that Paddington was included in the area of supply of the Metropolitan Company.

The Strand Vestry.

Mr. H. L. CRIPPS then addressed the Inspector on behalf of the Strand District. He said that under the Act of 1888 it was expressly provided that no Provisional Order authorising electric lighting should be granted by the Board of Trade except with the consent of the local authority, unless the Board of Trade in any case in which the consent of the local authority is refused are of opinion under all circumstances that that consent ought to be dispensed with. This responsibility cast upon the Strand District induced them very seriously to consider the whole question of electric lighting in their district. There were five companies making application for Provisional Orders, and the first thing the Strand Board set to work to consider was whether any, and if so which company, was in the best position, financially and generally, to merit their support. The result of a great many interviews and much correspondence was the form of agreement which has been referred to as having been arrived at between the Strand District and the Metropolitan Company.

THURSDAY, APRIL 25.

The Inquiry was resumed on Thursday morning, and the case of the Strand Vestry was proceeded with.

Mr. H. L. CRIPPS said: With regard to the agreement between the Strand Board of Works and the Metropolitan Company the points gained in it were first, the definite appropriation of the different stations as the source of light in the district; second, the definite allocation for distributing mains throughout the entire district in positions satisfactory to the local authority; third, the security that from these stations and mains an adequate supply of electricity will be produced for the district; fourth, an easy means of detecting the cause of any failure or deficiency in the supply of the district; fifth, an easy access to head-quarters, situated in the district, to lodge complaints and obtain a remedy; sixth, definite arrangements for preventing obstructions in the streets; seventh, the relief of the Board of Trade from the task of arbitrating between the local authority and the company with regard to works in the streets; eighth, freedom of the consumer from various onerous conditions with regard to his obtaining a supply, and arbitrary powers contained in the Provisional Order; ninth, a system which augurs as fairly as possible for a harmonious working between the local authority and the company. These points he claimed to have gained under the arrangement. There was one other point—that of friendly competition—which had been put forward mainly on behalf of the London Electric Supply Corporation. In the Strand it was especially important, because at the most they could not find room for more than two sets of mains. Therefore, when the London Company asked to be admitted as well as the other company with whom the arrangement had been come to, it followed that between them they would have an absolute monopoly in the Strand. Under the express provisions of the Act of last session the Board of Trade could hardly without strong cause shown override the consent of the local authority. He assumed the Inspector would agree with him in thinking the Provisional Order of the Metropolitan Company ought to be granted. Then came the question whether, in addition, the powers should be conferred upon the London Company. The Strand Board felt that the consent to the London Company's order ought to be withheld. It was obvious that the dealing with the jointed mains must involve more street disturbance than the system proposed by the Metropolitan. In a main seven miles long, in pieces of copper conductors about 21 feet each, there would be something like 1,760 joints. The mere question of the expansion and contraction of copper offered in itself a difficulty; its advantages seemed to him to be the less cost of coal and supervision and the removal of smoke from London. Examination of the Whitehall station had satisfied his clients that there was no objection on account of smoke; it did not seem to him that the production of the 120,000 lights for the Strand would cause any appreciable difficulty in regard to smoke, coal, &c.

Mr. G. H. COLE, examined by Mr. H. L. CRIPPS, said that he was a member of the Strand District Board of Works and a member of the Electric Lighting Committee of that Board. The opinion of the committee was that if the Metropolitan Provisional Order was modified in accordance with the agreement it would afford a satisfactory solution of the electric light question in the district.

Mr. PEMBER: Now, for instance, take clause 8, which fixes the price. That is completely against what Parliament has hitherto considered the proper policy, is it not?

Mr. C. A. CRIPPS: That is a matter for argument.

Examined by Mr. HUNTER: The eight conditions were not sent to the Storage Company. He believed that when the applications were first made for licenses the Storage Company was one of those which was put aside as not satisfying the requirements of the committee.

Just let me ask you this. Before you determined to confine the competition to the London Electric Light and the Metropolitan Companies had you made any inquiries as to the systems of lighting which these companies proposed?—I am not aware that we did.

Did you know what was the system proposed by the Metropolitan, and had you compared it with the system proposed by the Electric Storage Company?—No, I believe not. As to electricity being supplied for use in motors, the witness continued that the committee only dealt with lighting. They did not go into technical matters, but they saw that the system of the company selected was in perfect working order by the example of the Whitehall-court station: they knew there would be no storage in the system applied by the Metropolitan Company to the Strand. From what the committee had learned of storage it certainly did not in any way meet with their approval. By the agreement as originally settled both generating stations were outside the district of the local authority.

Now do you consider the bearing of that fact upon the provisions of the Act which enable the local authority at the end of 42 years to buy the plant?—I do not think that point perhaps was considered.

Of course you must see that at the end of 42 years if you deal with the company which has its generating stations outside the area that all you can buy will be the pipes and mains.—The WITNESS: Why not the tation?

Because it is outside your area.—Why not purchase that as well as that which is within your area?

You can purchase voluntarily of course, but I am speaking of the compulsory powers to purchase supposing they did not want to sell.—It is the company's property.

Major MARINDIN: That is a matter for argument.

Re-examined by Mr. H. L. CRIPPS: At the inception of this matter the witness himself was a very stout advocate of the London Company that they should have a fair hearing.

* See *The Electrician*, April 12, p. 658.

Wandsworth Vestry.

Mr. R. W. YOUNG was then heard on behalf of the Wandsworth District Board. He did not for one moment say that the Metropolitan Company was deficient in capital, but suggested that the Board of Trade should consider whether there should be a deposit or further capital raised in the way that was provided in the St. James's order. They also wanted a clause to prevent the buying up of any competing company in the future, and there should also be a limited area for the location of the generating stations. They thought some sliding scale should be incorporated in the order. With regard to price, they suggested that instead of 8d. the same price as in the St. James's order, 7d., should be inserted.

Mr. ARTHUR SOUTHAM, the Wandsworth District Surveyor, was briefly examined in support of Mr. Young's statement.

St. James's Vestry.

Mr. WILKINS then addressed the Inspector on behalf of the St. James's Vestry. He said that his observations would be addressed to the cost to be actually paid by the consumer for the current he obtained from the company. They had already consented to two or three orders and licences, and up to the present year not one of them had ever actually come into operation. In fact, he might say that the supply of electricity under the statute did not commence, as a matter of fact, until this inquiry had actually been opened. So far back as 1883 he represented the vestry before the Board of Trade, and they had come to see, he thought, that the views entertained at first by the local authorities, although perfectly legitimate at that time, seeing the utter absence of reliable information, were somewhat extreme in the light of the present condition of the science of electricity. On the other hand, the companies had advanced and met them in a much more generous spirit than they were disposed to do in the early days of the movement. The first question of policy was whether they should adopt a system of free trade or of districting. His district had large clubs and mansions, all of which might be expected to be large consumers of the current; but they had also the back part of the parish, in which the supply of electricity for lighting purposes at anything approaching its present price would simply be prohibitory. But that district was largely dotted with manufactories having small mechanical appliances - small gas and small steam engines—and that they did not view with any great satisfaction, but would be exceedingly glad to see the introduction of electricity for the purpose of power. As to the question of free trade *versus* monopoly, he did have some intention of calling Mr. James Beal as a witness, whose investigations in connection with the gas monopoly, and the eventual legislation resulting in the districting of the companies, were pretty well known, but his evidence would have been little more than a digest of official documents already in the possession of the Board of Trade. The vestry had adopted—on very common-sense grounds, he thought—the principle that districting was as essential in the case of electric lighting as it ever was in the case of gas; and more so, as in the first case the ground was now occupied by mains—there were no less than 15 companies at the present time having authority to lay mains along Regent-street. The present uselessness of many of these mains were largely due to the mistaken policy of free trade in gas in the early stages. If two electrical companies each of them laid a main at a cost of £100,000, and one main would suffice, then who would bear the loss? Well, to some extent that might be met by competition. But let this be remembered, that the electrical lighting companies are protected by a guarantee of 20 per cent. on the cost of their mains, whether they were necessary or unnecessary, for a period of three years.

Mr. LOYD: We do not assent to that.

Major MARINDIN (to Mr. Loyd): You can remark upon that.

Mr. WILKINS: Of course if the competition were equal, supposing the companies supplied each of them their 50 per cent. of the current from the main, no doubt competition would then be operative; but supposing we take it that there is a powerful company supplying 90 per cent. of the current for which the main was laid, and the other simply supplying 10 per cent., the condition of competition would then be absolutely unfair and unequal. He thought that the evidence of Mr. Ferranti would show that practically the whole system of the London Electric Supply Corporation was experimental: the dynamo that was to be constructed was to be very much larger than any that had yet been erected. The rigid concentric main was to be jointed at every 20 yards, and it was admitted that at every 20 yards there would be the weakest part of the system. There was, in addition, the potential of 10,000 volts, which had never yet been attempted even on a small scale, and here the experiment was to be made for a distance of seven or eight miles. The conversion was to some extent an experiment, and the question arose whether it was wise to entrust this company with so large an area to make their gigantic experiment upon. After prolonged inquiry and negotiation the vestry had adopted two competing companies—the St. James's Company using the continuous current at low-tension, and the Metropolitan Company which was doing work in the parish at a moderately high-tension on the alternating system. So they had adopted a middle course—they had neither gone in for free trade nor for districting, because, while they agreed with the districting they did not think that the time was yet arrived when a fair scheme of districting could be laid down. After reviewing the question of overhead wires, Mr. WILKINS said that it was important that they should have a system capable of supplying the current for motors. Taking Mr. Ferranti's evidence, that as a commercial matter a motor with an alternating current was absolutely unknown in England, that was one very fatal objection, in the opinion of the vestry, to granting to the London Electric Corporation an order which from the vastness of its operations would probably very soon result in a monopoly. Another objection was the high potential, and they were not satisfied with regard to the insulation. It was claimed for the Deptford scheme that there would be a net economy in cost of production of 43 per cent. One would have thought that at any rate the consumers would have part of the benefit, but he found that the London Company sought power to charge 8d. per unit, whereas the maximum of the two companies who had assented to the terms of the vestry was only 7d. He proposed to re-call Mr. Swinburne on a new point.

Mr. JAMES SWINBURNE, re-called, examined by Mr. WILKINS, said he thought that there might be a saving of two or three shillings per ton in coal at Deptford, but he thought that the Metropolitan Company at Waterloo would be on the same footing. With reference to Mr. Ferranti having said in his evidence "our coal is half the price," that seemed to the witness to be too large a reduction by far.

WITNESS continued that he considered that the saving in superintendence in the Deptford scheme would be little or nothing, as the superintendence required at the distributing stations would counterbalance it.

Mr. WILKINS: Mr. Ferranti gave in his evidence that the proportion of the cost of bringing the current up from Deptford would be 7 per cent. to £100 on the capital outlay at the generating station?—Yes, I remember the figure.

You have seen the models of the main?—I have.

Then, taking the mains as given by Mr. Ferranti, what do you estimate the cost of one main from Deptford for seven miles, the hypothetical distance, would be?—It is rather difficult to estimate it; £14,000 is a very low estimate indeed. I have got here a piece of cable of the same area manufactured by the Silvertown Company, who are one of the leading cable companies. It is an India-rubber insulation, it is the same area, and the price is £2,500 a mile; but if you insulate it outside as well it comes up to £5,000 or £6,000 a mile. That is an extreme case, because the insulation they would put on would be probably better than the London Electric Company would require; but I think you may take it that £14,000 is rather too low a figure.

That is £2,000 a mile?—Yes.

Taking the cost of a station of 100,000 lights, and the cost of distribution at £150,000, what percentage do you make the cost of mains bear, to work out somewhere about 18 per cent.?—Something of that sort—nearly 20 per cent. instead of 7 per cent. The witness continued that he did not think the saving in going to Deptford would be anything like 50 per cent. He did not anticipate any nuisance from steam from local stations.

Cross-examined by Mr. GRAHAM: There was not much difficulty in making a small alternating current motor up to one horse-power, but when you got to large motors the difficulties would be very great. He was making a small quarter horse-power one himself, but there were great difficulties to be overcome before he could make it commercial.

FRIDAY, APRIL 26.

St. George's, Hanover-square Vestry.

Mr. JOSEPH HENRY SMITH, Vestry Clerk of the Parish of St. George's, Hanover-square, examined by Mr. HITCHINS, said there were four companies making applications for Provisional Orders in St. George's Parish—the London, the Metropolitan, the Westminster, and the Chelsea. Taking the London as a standard, their principal objections to the orders were—the length of time for compulsory works, which they thought should be reduced to eighteen months, the placing of overhead wires without the express sanction of the local authority, and the penalty clause. The next serious objection they had was with regard to the power which was proposed to be given for the suspension of the order by the Board of Trade. There were various other questions which the vestry considered material to be altered, but at the same time they were not of vital importance. Subject to amendment in these respects the vestry had no objection to the orders of the London, the Metropolitan, and the Westminster. Copies of the amendments suggested were sent to the Board of Trade and to the companies. Subsequently a letter was received from the London Company, on which the vestry passed the following resolution:—"That the vestry do now approve of the application of the London Electric Supply Corporation (Limited) for a Provisional Order to enable the corporation to supply electricity in this parish, but upon the express condition that the corporation accept all the alterations and conditions which have been insisted upon by the committee acting on behalf of the vestry, and that the order should be so amended as to clearly and distinctly embody the same." A similar resolution was passed with regard to the Westminster and the Metropolitan. With regard to the Chelsea Company, the vestry objected from the first to that company coming into the parish.

Cross-examined by Mr. MOULTON: The objections to the Chelsea Company were formulated in writing and sent to the Board of Trade. The main objection was that it did not undertake to light the whole of the parish.

Kensington Vestry.

Mr. HEWITT then addressed the inspector on behalf of the objections of the parish of Kensington. When the Kensington Vestry first considered the question of electric lighting there were six companies competing—the Metropolitan, the London, the Notting Hill, the Kensington and Knightsbridge, the House-to-House, and the Chelsea. The vestry immediately appointed a committee, the chairman being Mr. Jordan, and one of the most influential members Mr. Saunders, Q.C. The committee met the various representatives of the companies, and the whole matter was thoroughly discussed. The matters under discussion were the area of each company, the system of laying mains, the maximum charge to customers, whether smokeless coal would be used, as to laying underground wires, the system proposed to be adopted, and whether the companies objected to having wires in the same conduit as other companies. The House-to-House Company were willing to light the area pointed out as allotted to them; would lay mains in pipes near the kerb in footway, diameter of pipe to be 6in., and would put themselves entirely in the vestry's hands with regard to the method of laying mains. The varying scale of charges would be—first 100 hours 1s. per unit, second 100 hours 8d. per unit, third 100 hours 4d. per unit; could give light in any part of area in two months; vestry to have the right of purchase in 21 years, under the usual arbitra

Digitized by Google

tion clause. The Chelsea Company would not make a varying charge—the maximum would be about 8d.; would give vestry power of purchase in 21 years in proper arbitration clause. The Kensington Company would fall in with the views of the vestry as to the system of laying mains; the maximum charge to be 8d. per unit; would use smokeless coal; could not say positively, but was of opinion that they would give the vestry power of purchase in 21 years. The Notting-hill agreed in the main to the conditions of the other companies; maximum charge to be 8d. per unit; would adopt a sliding scale if found workable, and would sell to vestry in 21 years. The Metropolitan Company and the London Company withdrew their applications. He would say with reference to the question of generating stations that it was eminently desirable that in all cases before stations were created the sanction of the local authority should be obtained. He thought it was especially desirable in a large residential parish like Kensington, where property might be very seriously injured by the erection of works for the supply of electricity. The companies who propose to supply Kensington must not be looked upon as benefactors, but simply as speculators—speculators no doubt engaged in a very lawful and legitimate enterprise; but he ventured to think that the proper thing to do was to have regard to the views of the local authority in matters of this kind.

Marylebone Vestry.

Mr. H. L. CRIPPS, on behalf of the parish of Marylebone, said it appeared to the parish that the application of the London Company should not be granted, because, under the present scheme, Marylebone would be upon the extreme outskirts of the area of supply, and after all the evidence which has been given as to the possibility or feasibility of the London Company's scheme, it seems obvious that the position of Marylebone might be one of very doubtful advantage. The scheme which the London Company have adopted will entirely defeat, when the time comes for its operations, those provisions of the Electric Lighting Act which enable the local authority to acquire the undertaking. As regards the various questions which have arisen as between the local authorities and the companies, the parish of Marylebone has been approached by the Metropolitan Electric Light Company with suggestions for an arrangement which appears, so far as Marylebone is concerned, to be satisfactory to the authorities. They have come to an arrangement with the parish of Marylebone, which is now embodied in an amended Provisional Order which has been prepared. He could hardly say he was in a position to hand it in at the present moment because it had only reached his hand this morning, and of course requires very careful revision on behalf of the parish. Under it the Metropolitan Company come to an arrangement under which they are to provide within the Parish of Marylebone a station which shall be sufficient for supplying light to the parish. Much in the same way as with the Strand District, they are to lay down within a definite period a sufficient number of mains, on the assumption that they will be the parties in the first instance alone entitled to deal with the parish; and on that assumption they have agreed to a similar provision to that which had been arranged in the Strand case, under which the price to be charged in the first instance is to be substantially the same, but somewhat lower than proposed by the Provisional Order, and under which, at the expiration of every period of seven years, that price is to be subject to a revision by an arbitrator. Of course it is obvious that the parish of Marylebone differs very much from the Strand District; it is true that it is occupied by persons who may be expected to a large extent to be customers for the electric light, but it is equally true that a large part of the Parish of Marylebone is sparsely populated and inhabited by a class who would, at all events, not be customers. It could hardly be expected, therefore, that any electric light company would place itself with regard to the whole of the parish under conditions quite so favourable to the consumers as those which apply in the Strand District. As regards a great part of the parish of Marylebone, the Metropolitan Electric Lighting Company are the only applicants, and as regards that part, therefore, their application is unopposed. With respect to the southern part of the parish, however, the London Electric Company are also applicants. He said that if the Board of Trade sanctions the order applied for by the London Company as far as regards parts of the parish of Marylebone, it would certainly operate in a way which seemed to him to be very inequitable, unreasonable, and inconvenient to the parish. If it were granted the effect would be that the Metropolitan Company would be placed in competition as regards the best part of the district with the London Company. Therefore, on behalf of the parish of Marylebone, he would ask that, subject to the terms of this arrangement being carried out, the Inspector would recommend for acceptance the Provisional Order of the Metropolitan Company.

Mr. WALPOLE EYRE GREENWELL, examined by Mr. H. L. CRIPPS, said he was the solicitor for the parish of Marylebone, and had been many years vestry clerk. Electric lighting had received the very careful attention of the vestry, and the question had been submitted to a committee of the vestry. The arrangement arrived at by them was one which was thought would be very advantageous to the parish of Marylebone.

Cross-examined by Mr. PEMBER: Some months ago representatives of the London and Metropolitan Companies attended the committee of the vestry, and their views were well considered. Negotiations took place with the Strand Board of Works with regard to certain terms for forming an agreement for the admission into the Marylebone parish of the Metropolitan Company. The London Company did not propose any terms which would modify the terms of the proviso. He had proposed to the London the same terms as to revision of prices as he had to the Metropolitan. He had told the London, "If you put your alterations before us we will consider them." The terms proposed by the Metropolitan Company appeared to be satisfactory to the committee, but there were no definite terms proposed on behalf of the London. He believed he told the representative of the London Company what the terms with the Metropolitan were—he was certain he did so as to revision of price, and he believed also as to the other terms. At the date of the arrangement, if the London had accepted the same terms as the Metropolitan the vestry would have consented to their order as well. There was a resolution to that effect of the 6th of April. It was not one of the conditions of the Metropolitan Company that they were to have the exclusive right. The vestry would not agree to it.

St. Margaret's and St. John's, Westminster, Vestry.

Mr. H. L. CRIPPS, for the vestry of the united parishes of St. Margaret's and St. John's, Westminster, said it would be observed that the geographical position of the area under the control of the vestry is rather peculiar; the parish of St. George's, Hanover-square, was sandwiched in the parish of Westminster, and the latter thus became entirely divided. However, it was not very material, as the vestry proposed to withhold their consent to any of the Provisional Orders. They had had the matter under consideration, and he thought he was authorised to say that they adhere rather to the system of one company authorised in a particular area rather than two companies being allowed to compete and place their mains in the same streets. None of the constituents of the vestry had urged the vestry to consent to any of the Provisional Orders, and, therefore, the vestry came to the conclusion that so far as the Westminster portion of their parish was concerned they might be left in the advantageous position of waiting for a year and considering in the light of the information obtained at this Inquiry what would be the best course to adopt. As regards the Knightsbridge portion of the parish, however, two licenses had been assented to by the Vestry of Westminster to one company.

After a short discussion,

St. Giles' District.

Mr. H. C. JONES said he did not propose to detain them long on behalf of the St. Giles' District Board of Works, nor did he intend to enter into any technical discussion, because he felt sure that it had already been dealt with fully. With regard to the London order, his Board had had an opportunity, through the courtesy of the company, of inspecting the works at Deptford, and had obtained all the information possible, and having regard to such information they were of opinion—for what that opinion was worth—that it is desirable that electric light works should, as far as possible, be kept out of large centres of trade and professional businesses. He considered that the public authorities should be placed upon somewhat more favourable terms with regard to public lighting than is proposed at present. Any dispute as to price he thought should be referred to arbitration. Meters, he thought, should be examined in the same way as under the Gas Acts. He suggested it was extremely unfair that one district should be placed on more advantageous terms than another, and if the Metropolitan Company could give concessions to the Strand they were able to give them to the adjoining district on either side, so far as they were of a somewhat similar character. If not, he said that virtually the ratepayers in other districts would be paying towards the electric lighting of the Strand District.

Mr. H. C. JONES then offered himself for examination, and was questioned by Mr. CRIPPS with reference to the agreement with the St. Giles' District.

Lambeth Vestry.

Mr. J. H. SMITH was heard on behalf of the Lambeth Vestry, and was afterwards cross-examined by Mr. PEMBER and Mr. CRIPPS.

St. Pancras Vestry.

Mr. COATES, in a short speech, said that the parish of St. Pancras stands in an entirely different position from any of the other parishes in London, inasmuch as they themselves had got powers under Provisional Order passed in 1883 to light the whole of the parish of St. Pancras. He thought they would be more likely to make it pay than a company would be—they would have no dividend to pay, and could raise their money at 3½ per cent. Being entirely independent they thought that no company should be introduced into their parish with powers to compete with them.

Mr. MOULTON, for the Telephone Companies, said they simply wished that London should be kept in comparatively electrical quiet, and they would only require a clause in all orders which would ensure this.

Mr. CROMPTON put in the estimate for the Westminster Company and a list of the subscribers to the capital of the Westminster Electric Supply Corporation. The subscribers are—Lord Suffield, £250; W. Hayes Fisher, M.P., £5,000; Sir John Heron Maxwell, £5,000; J. Browne Martin, £50,000; Henry Kimber, M.P., £5,000; Alfred Baker, £5,000; Edward Vigers, £5,000; J. Gunn Richardson, £5,000; R. W. Wallace, £5,000; D. P. Sheridan, £5,000; R. Fowler, £5,000; James Maclean, £5,000; David de Pinna, £5,000; John Fleet, £5,000; H. N. Newbyn, £2,500; W. H. Baker, £500; H. A. Hunt, £5: and J. W. Hiscox, £5; making in all £113,260.

Mr. RUSSELL GRIFFITHS, for the City, submitted that no Provisional Order should be granted to the London or Metropolitan Companies. Mr. Preece had described the scheme of the London as a gigantic experiment, and he (Mr. Griffiths) suggested that there was not only absolute danger, but absolute extinction of light from the insulation gradually becoming insufficient. If they could get companies to come and light the City at a cheaper rate than that proposed by the orders, he failed to see anything in the Electric Lighting Act to prevent a local authority from contracting itself out of the Act if they could get the lighting done by contract.

SATURDAY, APRIL 27.

Mr. WALLACE, speaking on behalf of the Kensington and Knightsbridge Electricity Company, proceeded to deal with the objections of the St. Mary Abbott's Vestry. As to their requiring that the undertakers should keep separate accounts, he said that although this might be necessary in the case of a large area there was no reason for it in a compact district like this. Then the vestry required a restriction as to overhead wires. His

Digitized by Google

company had not on any occasion placed overhead wires except within their own property, and it would be very hard that they should be open to the competition of any company coming into the district with overhead wires, and they suggested that the vestry should undertake not to allow any other company to place overhead wires; if the vestry undertook to do that his company were willing to incur penalties. The company took this very early into consideration, and came to the conclusion that it was illegal to put overhead wires within the district for which they applied. The case of the United Telephone Company *versus* The Wandsworth District Board of Works was not an authority to govern any such placing of wires as was contemplated by electric lighting companies. That case was one of a solitary wire being carried across a street, and the question really turned upon whether the local authority had any property in the air above the streets. But if that case had been fought on the question of nuisance the result would have been very different. As to the period for the commencement of compulsory works, his clients had no objection to eighteen months being substituted for the two years, and his company would be willing to agree to a clause to meet the matter of the breaking up of the streets. The next suggestion of the vestry was that prices should be revised every seven years. That would be manifestly unfair to companies who were limited to forty-two years. Then the clauses suggested by the railway companies would practically lead to the railway companies getting a monopoly instead of the electrical companies, as the Underground Railway Company, for instance, could say "No, there is already an agreement with some other company that no one should cross this railway except themselves." Next, as to the ojections lodged by St. Margaret's and St. John's. It had been said that there was no demand for the light within that district, but he had applications in his hand from Princes-street, from Ennismore-gardens, and Kensington Gore, for a very large number of lights. The vestry had resolved that it was expedient to retain the power in their hands, but no evidence had been given that the vestry had made efforts to find the necessary funds to carry it out. The Chelsea Company's station at Draycott-place lay at some distance from the Egerton-gardens portion, while that of his clients was across the Brompton-road, in the course of erection, and the light would be ready to be supplied in the next few months, or as soon as the Provisional Order could be got. The chimney had been erected, the building erected, and the boilers had been erected, but the dynamos and engines had not been put down, although they were on order, and they were starting to fix the engines that day. Sir William Thomson and Dr. Hopkinson had admitted, although they were not here to represent the Storage Company's system, that the system of the Kensington and Knightsbridge Company met with their approval, although the system of the Chelsea Company did not meet with their approval.

Mr. MOULTON: They did not say that.

Mr. WALLACE: They were called against that system, and when he examined them they made that admission.

Mr. MOULTON: They gave no evidence of that sort.

Mr. SHIRESS WILL then addressed the Inspector on behalf of the House-to-House Company, chiefly as to the settlement of certain details of boundaries between the neighbouring companies.

Mr. WALLIS, on behalf of the Westminster Electric Supply Corporation, said that his was a company in an analogous position to the Notting Hill Company, but was a company which had certainly done more than the Notting Hill Company, inasmuch as it had chosen sites and had used a certain amount of preliminary capital in erecting a station with 5,000 lights. He had handed in a list of shareholders, and among the names would be found those of responsible men who could subscribe the amount standing against their names. Now how had the London Company gone to work? They first of all started in the Grosvenor Gallery and commenced to lay down an installation which, on their own admission, they had to abandon. Another use they made of their capital was to commence a system of overhead wires. That capital, according to their own confession, was wasted and had to be abandoned. Then again, they did not think of applying for a Provisional Order, but attempted to seize on certain portions of London in an illegitimate manner. What it amounts to is this—the London Company say their station is to supply a large area of London, and, although they gradually abandon portions of the area, they say this is to light London. They spend their money, they erect the station, they lay down the plant—and on what security? None whatever; and that is the way these gentlemen deal with the money they have taken from the shareholders, instead of waiting to see whether they will get their Provisional Order or not. Are these gentlemen to be trusted to look after the affairs of the company or the lighting of London? I say no, sir. I am convinced you will say no, sir, and that the Board of Trade will say no. Sir William Thomson, who was here as their witness, says their system is an experiment, and I will leave it there. Now, leaving the London Company, let me consider what position we are in with regard to the local authorities. St. George's, Hanover-square, say they are satisfied with this Westminster Company, and it is to the local authorities that you must look to investigate these matters, and not to the rival companies, who, when provoked, say nasty things one against the other. With regard to the vestry of St. Margaret and St. John, Westminster, they have refused all companies alike. We abandon the Strand, St. Martin's, and all those places where we come in contact with the Metropolitan Company and the E.P.S. Company.

Mr. MOULTON said that in the cases of the two companies he represented there was almost every variety of the problem which is now before the Inspector. In the case of the Chelsea parish he represented a company that already had a Provisional Order, and had begun to work under it. In the case of the piece of the South Kensington area which was sought to be added to the Chelsea area, he thought that an application in a parish in which the local authority had gone most carefully into the matters, and had laid before the Board of Trade some exceedingly important recommendations, was indicative of the great care and thought which had led them to advocate a strict system of districting. As regards capital, the whole question was gone into by the Board of Trade in 1883, when the question of Provisional Orders came up, and he thought the conclusions he came to, after much patient thought, were very sound, and needed no departure from at the present time. The substance of those conclusions was this—that a company must satisfy the Board of Trade that it had proper and sufficient capital to do its work, must appropriate it to local use, and in all cases put down a portion of that capital as a guarantee that it did not idly take up the obligations of its order without any substantial intention of carrying them out. He thought that the question of satisfying the Board of Trade that sufficient capital was appropriated was not a matter to be done at this Inquiry; but at the moment the Board of Trade called such evidence, both his companies were in a position abundantly to satisfy the Board of Trade. Indeed, he might say for the E.P.S. Company they had already satisfied the Board of Trade of their financial strength being sufficient for the obligations they proposed to undertake. With regard to what had been said of the intention of the E.P.S. Company to obtain an order for themselves and to transfer it for a profit, it would be open to the Board of Trade to keep the E,P.S. Company as the undertakers. They had accepted the position as undertakers.

Mr. MOULTON had not concluded his address at the adjournment of the Inquiry.

The following estimate was put in by the Westminster Electricity Supply Company:—

Estimate of Generating and Distributing Plant.

2,880 horse-power of Babcock and Wilcox boilers, 8-feed water heaters, including fixing and setting, but no brickwork	£9,148
2,880 horse-power Willans engines, including bed-plates for the dynamos, all electric governors and other adjuncts, fixing in place	14,000
All steam and exhaust pipes and connections, all feed pumps, water tanks and water connections, fixing the whole	4,500
16 110-unit dynamos, each to give a current of 500 amperes at an E.M.F. at the terminals of 240 volts, including fixing automatic cut-off switches, complete	12,400
Switch-boards, regulating apparatus and instruments for the generating and distributing station	3,000
Accumulator plant, consisting of 252 73-plate accumulators, each provided, in metal lined cells, with cast-iron stands, insulating trays, and all supports and accessories	7,350
Travelling crane and workshop tools	350
Total for generating station	£50,748

Distributing Plant.

Mains:—Victoria-street, 2,000 yards of culvert; Whitehall, 600 yards of culvert; York-street, St. James's-street, Buckingham Palace-road, 1,300 yards of culvert. Including all surface boxes, bare copper main insulators, straining connections	9,500
Batteries, switch-boards, and regulating apparatus at distributing station, Buckingham Palace-road	4,900

MONDAY, APRIL 29.

Mr. MOULTON, continuing his speech, said there was not the slightest intention on the part of the E.P.S. Company of any sale or any transfer of one shilling of the profit. The subscribed capital would be tied up strictly in the way the Board of Trade think it desirable to tie it up, and it should not be thought for one moment that this was an attempt to get an order and make a traffic in it or transfer it in any sense. The precedent of the transfer to which he had referred was the following:—In 1883 the Crompton-Wingfield Association applied for two or three orders, and before the orders came on they formed a company. He did not know whether there was any subscription, but they formed a company named the Incandescent Lighting Company, and orders were granted to the Incandescent Lighting Company, even though all the notices had been given by the Crompton-Wingfield Association. What the Board of Trade did then was to look at the substance of the matter instead of the form. They required to be satisfied that substantially the application was to be carried out by the same persons by whom it was substantially made, and that these persons were prepared to put down the money to secure it, and then as soon as they were satisfied of that they took no further notice on the point. A similar case occurred in the case of the Chelsea Company. There the notices were given by four private persons. Before the order was actually passed into law the Chelsea Company was formed, and they are the undertakers under the order. He thought the real thing was to find out that there is capital which will be appropriated to the working out of this order, and that the persons who are going to work the order are persons who are of such standing as may be trusted with it. Now on this point he believed the Board of Trade were already satisfied; but if not, they should be satisfied in any way that they might desire by his clients. In referring to the question of system, and how the transformer system affects the need of further provisions, or justifies a relaxation of the model order, he should submit that so far from justifying any departure from the model order it only emphasises the importance of the prudence of the obligations under that order. He should put before the Inspector that still the direct supply beyond question was the best for the consumer, and that if the direct supply is to be given, and given effectively to the public, all the obligations of the model order should be insisted on, and he was sure they would be cheerfully borne by all those companies who wished to do their duty. The transformer system differs from the direct supply in that the natural inducements to do its work thoroughly and make electric lighting a thing used from house to house are absent. The London Company seemed to him a company that had seized on the one great feature of the transformer system, namely, that it would enable them

Digitized by Google

to hold the City so that no competitor could come in, without really giving to the public electric lighting in the best way; and under the guise of "Down with monopoly" he thought they were asking the Board of Trade to sanction an attempt which would leave London (if it were successful, which he trusted it would not be) as much at the mercy of a large corporation as it has hitherto been at the mercy of the gas and water companies. For motive power the direct supply was the only form of supply that could be used. Now is motive power an important thing? Lord Crawford, who represented a company which admits it cannot supply electricity for motive power, said that he believed the demand for motive power would considerably exceed that for lighting. There were signs of that already he (Mr. Moulton) thought in the increased demand for gas as a motive power, which, on account of the skilled labour required, and other things, was placed at a great disadvantage compared with electricity, a power so simple that the least educated man could use it without any previous training, and so free from objectionable element that it could be used anywhere from the parlour to the workshop. It had been suggested that one or more persons had solved the difficulty about the alternating motor, but to his mind it was all in the air. The transformer system was a thing which proposed to bring into every house electricity under circumstances in which it would be dangerous to life and property if there was from any reason an escape. He quite admitted the value of the safeguards against danger, but it still remained true that electricity was brought into houses under dangerous circumstances in a way in which he could not see that one could prevent imprudence or carelessness from making that danger a very probable one. He could not see that the transformer system was a cheaper one—nobody had brought figures to show that it was cheaper. Where was the advantage of the transformer system? It had been applied in 120 places in America, and in several places, apparently, on the Continent, and it was now being applied in England. The evidence of Mr. Knight had not been contradicted. It was that when you had got straggling areas the transformer system was the best, but nothing had yet contradicted the notion that the direct supply was cheaper where you had not straggling districts; and the question here was of districts of a manageable size. That was the real question the Board of Trade would have to decide. Were they going to say that now, when it is practicable to pick up the plums of a large area—were they now going to relax the very regulations which the fear of that being done made them put into the order of 1883? Now, dealing with the question of the two methods, he thought he was justified in taking the case of the London Company. He admitted that it differed from the Metropolitan. The Metropolitan was a company which was wanting to get as many areas as it could. Whether it would do them was another matter. It boasted enormously of its capital. It talked about half a million subscribed, and it turned out that at six stations they had already committed themselves to £350,000, so that they had only £150,000 left for the enormous area beyond. If its capital was compared with the area it was applying for, instead of being a rich company it was the most miserably poor company which had come before the Inspector. Even the London Company asked for only something like two-thirds of what the Metropolitan asked for, yet it had got a capital of about two and a-half times the size. The London Company had pushed the transformer system to its legitimate consequences as far as electrical engineering was concerned, made it possible to pitch upon any portion of their enormous area and light that from Deptford. Supposing they got their area they would be able to do the best piece of the City for its day lighting, the best piece of Chelsea for the purpose of strangling the Chelsea Company, the best piece of the Strand and of Marylebone. They had adopted the system which would enable them to take the plums, and they asked for a large enough slice of London to give them sufficient plums. Now he wanted to contrast the aims of the Board of Trade in 1883, and their means of carrying them out, with what were the aims of this company, and their means of carrying them out. The object of the Board of Trade was not to let a company have powers over a district unless there was a reasonable certainty that they would put the electric light within the reach of the whole of the people in that district. The "B" districts were only with great difficulty accorded to the companies, and the only reason why the power of extension was given to the companies was this—that if they took the pioneer risk it was just to give them the opportunity of a moderate extension without the expense of further application to Parliament. But the Board of Trade knew that those companies' only object was to develop electric lighting; they had no opportunity of picking out plums, and they required the allocation of capital; and, above all, there was the clear understanding that they were not statutory monopolies—that if they did not succeed in doing their work other companies would be allowed to come in, and that they embodied in the well-known clauses of the model order. He accused the London Company of deliberately intending to do the plums. If he was right those clauses must have made the London Company wince, and those clauses were left out. Were they or were they not to begin with compulsory mains? What did the London Company propose to do in the way of actual works? Not one single yard of main did it undertake when it lodged its order. They now undertook to do in Chelsea the same compulsory mains as the Chelsea Company undertook to do in 1886 in order to get their small area. The London Company had 16 square miles of London, and yet this was the only compulsory obligation they took upon their shoulders. It was to give a mock appearance of equality with the Chelsea Company. If an obligation the same as was put on the companies under the model order of 1883 was put on the London Company, where would their capital be? Their capital was big enough to hold London—but not to light it. The 250,000 candles they admitted would be just about big enough for a quarter of a million of people. Then there was the clause "capital allocated to do these areas." The London Company had left this clause out. They did not allocate a single sixpence, and what was the reason of that? Why the reason was too obvious—that they did not mean to do London. They intended to do such bits as would prevent any other company coming in and doing their leavings, or even competing with them in the pieces that they do. They had not omitted the clauses of the model order inadvertently but deliberately, and they knew that those were the most important clauses, and they omitted them because they were fatal to their scheme. As to the two points which had been brought up in support of the abandonment of the model order—the first was that the Board of Trade were themselves committed to the reasonableness of this form of order because the St. Martin's-in-the-Fields order and the St. James's license were similar in form. There could be no argument more fallacious than that. The St. James's license ran about 400 yards each way and was in an exceedingly rich district, and so small that it might be left to the company to lay down mains, and St. Martin's was very much the same thing. Then it was suggested that the local authorities themselves did not wish for it; but local authorities could not be expected to understand these matters—many of them seemed never to have noticed the illusory obligations that the Metropolitan and the London took upon themselves. As to the cry of "No monopoly," there was nothing to justify the Board of Trade in now coming to a different conclusion from what they did in 1883, that potential competition and judicious districting were better for the public than competition within the same area. With regard to breaking up the streets, the thing was exactly the same as it was before, and the Board of Trade was not now willing to allow overhead wires any more than in 1883. The third thing the Board of Trade relied upon so much was the competition of gas. If you took what gas could do in 1882, its competition was now immensely more dangerous when the gas companies had awakened up from their lethargy. Then mineral oil was a much more efficient rival than in 1882. If the rivalry to the electric light was sufficient in 1882 it was more so now. Now what justification was there for thinking that the gigantic system of the London Company would lead to cheaper electric lighting? Their charge of £5 a quarter did not look as if they were going to do any small lighting at all, and there was no evidence that they did not mean to go up to their maximum. If it was considered that about three or four hours represented the bulk of the electric lighting, and that there would be a leak during the whole of the remainder of the 24 hours. When he (the learned counsel) had asked how the many difficulties of the scheme were to be overcome he had always been answered that Mr. Ferranti had got patents. If this scheme broke down it would discredit electric lighting.

Now let him come, the learned counsel continued, to the Electrical Power Storage orders. The two parts applied for were Paddington and the Strand. He could not think that the vestry would continue its opposition to a well-considered scheme. They were willing to allocate the capital, and had undertaken to put down £30,000, and he did not see what more they could desire. With regard to the Strand, St. Martin's-in-the-Fields had no objection to their coming in, and the Metropolitan Company was entirely put out of competition by the fact that it proposed to give a private agreement to the Strand and refused it to St. Martin's. His clients ought to be admitted into the Strand, if only on account of the theatres. He would not occupy the Inspector longer in detail, but the more he looked it at the more he felt that the London Company's order was simply an attempt to hold London.

Mr. C. A. CRIPPS then replied on behalf of the Metropolitan Company. He said that Mr. Moulton had really based his argument on two contentions—first of all, that the matter of districting as against competition was settled once for all by the Board of Trade in 1883. So far from picking and choosing his clients put the whole district on the same footing. They had made arrangements for generating stations for 350,000 lights; they had 700 shareholders; their capital had been subscribed by the public nearly twice over, and they had power to increase it. The Chelsea Company, on the other hand, was in the hands of contractors. In Paddington the competitors of the Metropolitan Company were the E.P.S. Co., but his clients applied for the whole of the district and the E.P.S. Co. for only part, and Mr. Dethridge had expressed a very decided preference for the Metropolitan system. In Marylebone the Metropolitan had the assent of the local authority, and the negotiations had been straightforward. With regard to the South London order, Lambeth was in this position, that they said they preferred the Metropolitan to the London because the Metropolitan applied for the whole district, whereas the London applied for only about a quarter, taking out the best part. But he must admit that there were certain conditions which Lambeth asked which it was very improbable that the Metropolitan Company could comply with; for instance, to come under obligations as regards about 34 miles of streets in a long straggling district. That was an obligation which no company, he thought, would undertake. He believed the Lambeth district went right down to Croydon, and in some parts they would get hardly a penny return. Wandsworth, he gathered, wished them to go there, the local authority making as good terms as it could. In Wandsworth there was no competition; it was really a question between the company and the local authority. He would deal with the Mid-London Order on the following day.

(To be continued.)

SOUTH OF ENGLAND TELEPHONE COMPANY.—At their meeting yesterday, the directors of this company declared a dividend of 6 per cent. per annum on the Preference shares for the half-year ended April 30.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—At a meeting of the Board of Directors of this Company, held yesterday, after placing £7,000 to renewal fund and £6,400 to debenture redemption fund, and writing off the rebate on issue of debentures - viz., £26,100—it was decided to recommend at the forthcoming meeting of the Company that a dividend of 9s. per share (free of income tax) be paid. This dividend, with the interim one already paid in November last, makes a total distribution for the past year of 5 per cent. per annum, as compared with 4½ per cent. for the year 1887.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"Underground Conduits and Electrical Conductors."*

BY JOHN B. VERITY.

(Concluded from page 716.)

There is really sufficient subject matter for a Paper on conduits alone, and in taking up the question of underground conductors I propose to chiefly restrict myself to a consideration of conductors for high-tension electric lighting circuits.

With regard also to underground conductors for low-tension work, I feel that the Edison system, as at present laid down, is thoroughly capable of filling all the requirements of house-to-house distribution. Many companies in the States and elsewhere are using it, and at the down-town station in New York it has been at work for the past six years successfully. In the recent discussion on Prof. Forbes' Paper several points of interest concerning the Edison underground conductors were explained, which it would be unnecessary for me here to repeat. A full description of the latest developments of this system, with samples of the improved form of conductors, &c., are now on the ocean, and in the event of it being possible to provide another evening for a continued discussion of this Paper, I shall be most happy to show and explain them.

Everyone must acknowledge the foresight shown in devising such a complete system of underground mains so long ago, and which, in spite of the all-round developments of electrical engineering, not only holds its own, but is still far ahead in completeness of any system for low-tension underground work. The Westinghouse Company have, I understand, acquired the rights for Great Britain, and presumably will use it in connection with large transformers for sub-centres. It may be also interesting to note that Messrs. Siemens have made *concentric* three-wire cables, which are being successfully used at Elberfeld, Geneva, and Mulhausen, and they state that the troubles from what would appear very complicated jointing have been satisfactorily overcome.

It is underground conductors for high-tension currents that I propose now to deal with. A principal point for consideration is the necessity or not for lead sheathing where conduits or ducts are employed.

As to the durability of lead much absurdity has been talked. It is notorious that lead pipes have been in the ground under all manner of conditions, and at the end of long periods are still intact. There are, no doubt, certain clayey soils where lead has not much lasting power, but the lead may be materially preserved by coating it with coal tar, well tapeing it, and again soaking it in the coal tar or some such protective composition. Again, as Dr. Werner Siemens recently said in reply to Professor Forbes' Paper, owing to the manner in which the lead covering is generally put on to such cables, viz., by heating the lead to the point of melting, and forming it in this condition round the cable, while passing through the press, there is no certainty of a uniform thickness, and it is very difficult to obtain a tube through which damp, in course of time, will not find an entrance, as air-bubbles and impurities in the lead are liable to make the covering porous. A far better result is obtained by covering the insulated cable with a cold-drawn lead tube, as the air which might still be contained in the lead block is compressed to a minimum.

A theory as to partial wasting of lead covering on cables is that it may occur from acid being present in the jute or fibrous insulation, or, again, that the petroleum residuums may set up a chemical action on the lead; but there has not been much evidence on these points. Manufacturers of lead-covered cables have admittedly put on too thin a coating of lead in the earlier days; this has been gradually increased, and with proper conditions and precautions there should not be much fear of its durability.

Iron-armoured lead-covered cables are not necessary if an effective system of conduits is used for mechanical protection. In Berlin, where such cables are employed, they are simply laid in a trench in the ground, and consequently require to be thoroughly protected from mechanical injury. Lead alone is not sufficient.

Dr. Werner Siemens said in his recent Paper, that long years of experience had taught him that although covered with hemp or jute it requires further protection to render it secure against mechanical injury, whether by men or animals, as even rats eat their way through. Such protection is afforded by a double spiral of sheet iron, which again is made secure against oxidation by asphalting or galvanising, or by another cover of tarred hemp or jute. Such armouring as this is quite needless with a well-constructed conduit, but as to whether galvanic action takes place Dr. Siemens has undoubtedly shown by his firm's experience that with a substantial layer of tarred or asphalted jute between the metals it does not occur. This form of armoured cable was laid at Munich for lighting the theatre, and after nearly five years in the ground is as perfect as at first. At other central stations—at Elberfeld, Darmstadt, Geneva, Salzburg, Lyons, The Hague, St. Petersburg—their iron-armoured lead-covered cables prove that constructed in this way there need be no fear of galvanic action at any rate.

Lead sheathing may be made durable, but the actual necessity of it where a conduit is used is quite another matter, and a consideration of the two principal divisions of insulating material has considerable bearing on this point.

Of the fibrous and the homogeneous the latter seems to present some important advantages for insulating high-tension cables. For instance, vulcanised rubber is flexible and tough, and affords a continuous and homogeneous covering which should be superior to a fibrous covering. Vulcanised rubber cables are at times sheathed with lead for mechanical protection, but such is not necessary if laid under good mechanical conditions, and Mr. Lant Carpenter recently said that the sulphur in the vulcanised rubber would attack the lead in the same way it would copper. If, as is stated by many English cable manufacturers, compound vulcanised rubber will well withstand the deteriorating effects of damp and gases, then, the mechanical protection being afforded by a conduit, the necessity of lead as a protector is no longer of importance. It is true unprotected vulcanised rubber cables in conduits have failed in the States, but the competition among Electric Light Companies in America is notorious, and the question as to the maintenance of cables is not considered so much as their relative first cost. The object of the American cable manufacturers, naturally suiting their market, has been to make cables with a cheap form of vulcanised rubber insulation to compete with the jute insulated cables there, and which are cheaper. The vulcanised rubber evidently was not properly prepared, as it should be to permanently counteract the deteriorating effects of damp and gases, by reason of the expense.

All those acquainted with the rudiments of rubber manufacture must be aware of the enormous difference in quality of different vulcanised rubbers. With Para rubber at 3s. per lb., and the desire to sell it at a shilling, all manner of substitutes and compounds have been introduced. While thoroughly appreciating the energy and genius of American electricians, we can confidently say that cables manufactured in this country are greatly superior to those made in the United States; and, as a basis for this belief, we have the fact that most of the cables for high-tension distribution in the States have proved faulty according to their own admittance, while there is undoubted evidence of the successful working of many vulcanised rubber and jute insulated cables in this country and in Europe made by English manufacturers. The statement is made by the Silvertown Company, Messrs. Henley and Co., and others, that they are absolutely prepared to guarantee for a term of years their vulcanised rubber cables unprotected by lead, even if laid in damp and leaky conduits, provided there is suitable mechanical protection against injury and that the cables are laid under competent supervision.

With regard to *fibrous* insulating material, it is alleged that it has the defect of opening cracks when bent. If this be the case, it would became more pronounced when the material is soaked in resinous compound, and perhaps less so when petroleum residuums are used, such as for instance in ozite, kerite, bitite, &c. If cracks are likely to be formed when the cable is bent or twisted about, air paths would be opened up for disruptive discharges.

In the working directions given for the laying of one of the principal lead-covered cables in the States, it says:—"The fibrous material being superdried will readily absorb and retain moisture from the air, and cables showing an insulation resistance of thousands of megohms when first made may after exposure of a small part of the core to moist air for a few hours show a great falling off of insulation resistance." Instructions are therefore given as to carefully sealing the ends of the cable when laying. Again, the 'splicers' hands are cautioned to be kept "perfectly dry and free from perspiration, as a little moisture communicated to the insulation may result in vastly lowering the insulation resistance." These remarks, written by manufacturers of such cables, show the readiness with which such fibrous insulation may deteriorate under conditions likely to occur even if there be the most careful supervision of the men laying the cables. It is acknowledged to be absolutely necessary to cover jute or cotton insulated cables with lead, and it is in this fact that the weakness of such cables seems to lie, as the moisture and gas resisting portion is the lead absolutely, the jute insulation being of little value in this respect. Inasmuch as the majority of underground cables in the States are insulated with such jute or cotton soaked in some compound, it will be at once understood why lead-covered cables are considered in America as the only means for successfully carrying out such underground cable work, especially when the cables are liable to be laid in leaky conduits. It is right to say that apparently few troubles have been experienced in Europe with underground conductors insulated with fibrous material. Messrs. Siemens and Halske, who use a jute covered cable, but manufactured in a different way both as regards the impregnating of the jute and the method of cold-drawn lead sheathing, have a successful record not

* Paper read before the Institution of Electrical Engineers, April 11, 1889.

Digitized by Google

only for low-tension cables but for the various concentric cables supplied to Messrs. Ganz and Co., of Buda Pesth, for 2,000-volt alternating currents. They assert that the troubles experienced with American underground cables, whether jute or rubber insulated, are comparatively unknown.

The question between what I broadly term lead sheathed jute or well compounded vulcanised rubber seems to me the momentous one, and as usual each one has certain claims.

It is well known that the cost of jute insulated cables is less than that of high-class vulcanised rubber insulation, but this would have little weight unless they can be proved in every respect equal to vulcanised rubber. In a comparison of the different costs of such insulation vulcanised rubber appears to be about 25 per cent. more for approximately the same insulation resistance. In making this comparison I took the cost of a vulcanised rubber cable, insulated with one layer of so-called pure and two coatings of vulcanised rubber, taped, braided and coated with preservative compound but not covered with lead, as this is a superfluity, the cable being watertight without this addition. The jute insulated cable I took as cased with lead and protected again by a covering of tarred jute yarn compounded.

After the relative cost comes the question of jointing, and as this is one of the most vulnerable points in any cable it is of vital importance that the joints should be made as good as any other part. With vulcanised rubber cables the joints must be vulcanised, and first-class rubber men who would make such joints speedily should be on the working staff. With lead-covered cables a plumber would have to be employed, and I am informed by those who have had experience with both forms of cables that the vulcanising is preferable to the plumbing.

Vulcanised rubber cables are certainly easier to handle, being more flexible, ductile, and lighter, and this is of importance in view of the difficulties occurring in drawing cables in and out of a conduit.

Again, when lead-covered cables are coiled round a drum the part nearest the centre becomes compressed, while the outer portion is extended; on uncoiling the cable the opposite effect is produced, the parts before compressed being now pulled out and the extended portion compressed. This is trying to an inelastic substance like lead, the more so when, unlike an empty lead pipe for water, it is filled with an insulated cable. It is quite conceivable that the surface of the lead may be slightly broken up, particularly when the method employed is to cover the lead hot round the cable; and although no cracks may be visible to the eye, gas and moisture might be apt to find their way in very quickly, with corresponding deterioration of the insulation.

Next, as to whether jute or vulcanised rubber is better suited for insulating high-tension alternating cables no opinion can yet be given. It is well known that on submarine cables working with reversed currents it is usual at times to give the cable a rest. This necessity may be due to the action of the reversed current on the insulation, and it would be interesting to know how the much more powerful currents and rapid reversals of an electric light circuit will affect the insulation of a cable after carrying such currents for a considerable period. In some interesting Papers, published last year by Mr. Addenbrooke, he came to the conclusion that a high-tension alternating current should have less effect on any dielectric than a continuous current of the same potential. He argued that owing to the rapid alternations there would not be sufficient time to fully charge the dialectric, as before this could occur the next charge would sweep out the former charge, partially recharging it in the opposite direction. But it would certainly appear that such an action as this on a dielectric would be far more injurious than for it to be fully charged as with a continuous current.

From a careful review of what I have seen in the States and elsewhere I must confess that my own feeling is in favour of a cable insulated with thoroughly good vulcanised rubber for high-tension work, and I was interested to hear Sir William Thomson say on Monday at the Board of Trade Inquiry that if high-tension conductors were protected in an iron pipe a lead sheathing to them was not essential.

Those acquainted with the present manufacture of rubber cables know that pure rubber proper is not used for their insulation. However good the rubber may be there is always a certain amount of impurity and oils which will set up decomposition sooner or later. This is overcome by slightly vulcanising the rubber, but so that there shall be no surplus sulphur to attack the copper. In the high-class cables now made by the Silvertown Company and others the practice is to put next the conductor after cotton twist a substantial coating of pure India-rubber, slightly vulcanised, upon this a coating of zinc rubber with vulcanising materials, and covering this a compound vulcanised rubber of great resisting qualities to damp and gases. The zinc rubber takes up the surplus vulcanising material of its two outer coverings, so that the copper cable is not injured by the sulphur used in the process. Such an insulation as this is as good as could possibly be desired for any high-tension currents, and is absolutely perfect so long as the covering is continuous; and as the whole of the materials are treated at a temperature of 400 deg., any rise in temperature of the conductor due to accidental overloading will not injure the insulation. With regard to the outer protection of the compound vulcanised rubber, there may be still scope for further improvement, as, for instance, in the cables recently made by the Silvertown Company for the London Electric Supply Corporation two braidings of asphalted tape have been used, and this is found to be satisfactory. Among the instances where vulcanised rubber cables have stood stringent tests has been at Eastbourne, where Mr. Lowrie has used Silvertown cables laid in iron pipes for two years, and states they are still in perfect working order. He has also put down there a length of Fowler's Tatham lead-covered cable for continuous current high-tension work, the fibrous insulation being well wrapped round several times with tape. This has also been working successfully, and in the House-to-House Company's station he proposes to try each method of insulation on different circuits, although the advantages of handling the India-rubber cables are in their favour.

The Silvertown Company have five miles of vulcanised India-rubber insulated cable sheathed with iron wires at Brussels, with 1,400 volts constant current. This was laid in the sewers two years ago and is now quite satisfactory.

This company have also supplied two miles of such cable, but with asphalted tape on the outside, to the London Electric Supply Corporation, with 2,400 volts alternating current, the conductors being laid in an iron pipe.

There are also samples on the table of a piece of Messrs. Henley's vulcanised rubber cable that has been in use overhead for ten years.

A difficulty with underground conductors in the States seems to be disruptive discharges, and I trust the discussion may bring forth information on this subject. Owing to the frequent puncturing of the insulation, attended with pin-holes in the lead covering, Mr. Acheson, the Waring Company's able electrician, and whom I desire heartily to thank, turned his attention to the matter, as the pin-holes by admitting moisture defeated the object of the lead sheathing and proved fatal to the life of the cable.

Mr. Acheson's theory is that the static electricity generated in the cable after a time punctures the dielectric by discharging itself between the copper conductor and the lead sheathing, and the protector shown in Fig. 12 is designed to obviate this.

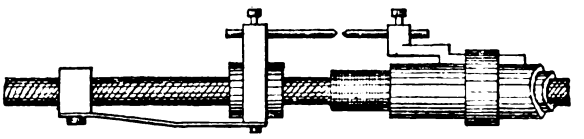

Fig. 12.—Mr. Acheson's Cable Protector.

This consists of two metallic points separated by a distance which is less than the thickness of the cable insulation; the one point is connected to the lead sheathing, and the other through a fuse wire to the copper conductor, the idea being that the static discharge would take the shorter path between the points instead of rupturing the insulation. Mr. Acheson says these dischargers should be placed at every section of a cable, and if the sections are more than 200ft. long there should be one at each end.

To show the exceedingly minute path necessary for a discharge it may not be out of place to quote Mr. Acheson's experiment. A plate of glass about one-tenth of an inch thick was broken in two pieces, and the two parts immediately fitted to their former position and clamped. The restored plate was placed between two discharging points, and so long as the points were over the solid glass no discharge was obtained, but upon removing it so that the line joining the points would lie in the plane of the fracture a discharge immediately occurred.

A possible cause of a disruptive discharge might be that on high-tension circuits of great self-induction—as, for instance, on arc-lighting circuits, where lamp coils form part of the line—the induced current on breaking the circuit is very violent, and in preference to discharging through the line, and consequently the lamp coils, it gets away by rupturing the weak insulation and passing through to the outer earthed casing.

The exemption from such trouble is credited by many entirely to a thicker insulation being used, and in calculating the insulation for a high-tension cable it should be made sufficient to withstand a disruptive discharge of this nature and tested accordingly. For instance, owing to the almost daily occurrence of burn-outs with some cables in Chicago with $\frac{3}{32}$ insulation, laid in November, 1887, the four miles laid in December, 1887, had $\frac{4}{32}$ insulation, and the two miles laid early in March, 1888, have $\frac{5}{32}$ insulation. Careful experimental work is essential before the sufficiency of insulation for such underground cables can be accurately determined, and our leading cable manufacturers naturally keep the results of such experiments to themselves.

Digitized by Google

Concentric cables, although so extensively used by Messrs. Ganz, of Buda-Pesth, in their stations, do not appear as yet to have met with favour in the States. It is, of course, undesirable to use ordinary lead-covered cables for alternating currents, both on account of the loss from induced currents in the lead sheathing and the annoyance to workmen handling them. If, for instance, while handling a conductor conveying such a current the lead covering be insulated to any extent on each side of them, the workmen would receive the induced currents through their bodies. Again, when the two legs of an alternating current are in separate cables, and the cables laid in insulating materials, any chance contact or connection between the leads might cause the induced currents to pass backwards and forwards at these points, thus tending to cut away the lead covering as the result of any sparking at poor contacts between the two leads. The Waring anti-induction cable, with both wires enclosed in one sheathing, is well known, and in this the currents induced by both wires being equal in power and opposite in direction tend to neutralise one another.

Mr. Ferranti, by employing concentric cables for conveying the high-tension currents from Deptford station, has brought such cables into prominent notice in England. A concentric cable is obviously the best on theoretical grounds for the elimination of induced currents, as their reaction upon one another is necessarily strongest in the axis of the current. The question as to the necessity of insulating the outer conductor of concentric cables has recently had considerable attention given to it by Mr. Preece, on behalf of the Post Office authorities, and as a result of his experiments they evidently must be so insulated. All the concentric cables made for Messrs. Siemens and Halske for Messrs. Ganz and Co. are of the usual stranded wire form, and the outside conductor, after being well insulated with jute, is covered with a cold drawn lead tube, having an outer iron armouring as previously described. These cables have been successfully used in Rome, Tivoli, Turin, and Milan, in each case carrying a potential of 2,000 volts.

The difficulty of making satisfactory joints with concentric cables must be to a certain extent against them, as it is impossible to see what has been done inside. Messrs. Siemens say that it can be readily accomplished. The Silvertown Company have made several forms of concentric cables, highly insulated with vulcanised rubber, with considerable success for ship work, and they also have an arrangement for constructing the joints.

As to whether concentric cables will be largely used in this country much depends upon the system of distribution employed. For long lengths of cable used as feeders to sub-centres, or to systems of distributing mains, they would be of considerable advantage, as no joints would be required *en route*, but in house-to-house distribution with frequent joints a pair of separate cables near to each other would appear the more easy to handle and the more practicable to operate. In summing up this matter it would appear that the relative advantages are as follows:—1st. The greater convenience of making joints on separate leads as against the trouble involved with concentric cables. 2nd. As regards the relative cost between two separate cables and concentric cables with the same insulation resistance, vulcanised rubber unsheathed concentric cables with outside insulation are dearer, but with jute insulation for concentric cables and lead sheathing they are cheaper. 3rd. There remains the increased efficiency on an extensive system of alternating currents by the use of the concentric form.

With regard to the second point, the figures showing these are:—

For vulcanised rubber, two Silvertown $\frac{1}{12}$ conductors insulated to 5,000 megohms at 60 deg. Fahr., taped and braided over all, specially prepared for underground work, £255 per mile each = £510.

A concentric conductor of equivalent capacity, the internal conductor insulated to 5,000 megohms, as above, but the outer to 3,000 only = £900, being a difference against the concentric conductor of £390 per mile.

If the outer insulation is reduced to 1,500 megohms the price falls to £630 per mile, which is £120 above the cost of separate leads.

On the other hand, for Messrs. Siemens' specially prepared jute insulation two single conductors of the same insulation at £220 per mile each = £440.

A concentric conductor of equivalent capacity, the outside insulated to 900 megohms, lead sheathed, taped and asphalted, £363 per mile.

All cables for high-tension currents should be well tested before leaving the factory. In other branches of engineering the engineer would not think of receiving his steam or hydraulic pipes without first seeing them tested to, say, over twice their working pressure; it is not sufficient for him to see simply that they will hold water or steam, but he must satisfy himself that they are strong enough for the pressure they have to carry. In the same way the electrical conductors which have to transmit energy, much as the steam and hydraulic pipes do, should be tested to twice their working pressure. With the outside well earthed, the current should be allowed to traverse the conductor a considerable time, and an electrical test taken afterwards for insulation. With electrical cables for underground work passed in this way, and satisfactory in other respects, there should be no fear of break-downs under ordinary conditions.

In dealing with a subject of such wide extent and great importance as this it is impossible to do justice to all the workers in the field. I have left out much that may be considered interesting and important, but the difficulty has been, with the mass of information on the subject, what to put in and what to leave out. Doubtless there are many instances of cables and conduits having been successfully at work which have not been mentioned in this Paper, and I hope such information will be forthcoming. If the discussion following be the means of clearing up some of the doubtful points surrounding the subject of underground electrical work, and of demonstrating the direction in which successful work should be undertaken, the object of this Paper will be fully accomplished.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 20, 1889.

One of the most interesting studies in American social and political life is to watch the manner in which the various bodies and authorities of the nation and the States exercise their different functions, which at the first glance to anyone unacquainted with the country would seem to be hopelessly contradictory and conflicting. The average visitor from abroad comes here impressed mainly with the idea that the United States constitute a great Republic, and very often he goes away after a short sojourn without realising that after all each State is an *imperium in imperio*. The fact is, that although the States have delegated large powers to Congress and to national officials, they still reserve to themselves individual legislation on most conditions which affect, directly and indirectly, the welfare of the citizen; and hence a large number of cases which in England, for example, are carried up from, say, Cornwall or Northumberland to the Imperial Parliament at Westminster, are disposed of at some such small State capital as Augusta, Maine, or Columbia, South Carolina. Now and then, however, the case presents itself as to whether bodies holding powers and franchises from Congress are not enabled thereby to free themselves from conditions imposed locally in the different States, and just such an issue has now been raised by the Western Union Company in this city in its endeavour to escape from the provisions under which the New York Board of Electrical Control lives, moves, and draws its salary. Telegraph companies that have accepted the restrictions and obligations of laws passed by Congress have thus become business agencies of the Government, and are given the privilege to construct, maintain, and operate lines of telegraph "over and along" any post road of the United States, provided they do not interfere with ordinary travel. It has been decided that wherever a postman goes is a post road, and as every street in New York is visited by postmen it follows that they are all post roads, to which the Western Union Company, having accepted the national terms, has right of access. The same statement of affairs applies to railroads, all of which carry the mails, and are therefore post roads along which telegraph wires may be strung. In fighting the Board of Electrical Control, and invoking the aid of the national court, as it did last week, by asking Judge Wallace, of the United States Circuit Court in this city, to give it an injunction against the board, the Western Union Company took the ground that the State authorities or laws were invading the national jurisdiction, and that there was no defence for the board's conduct in trying to drive the telegraph wires underground. Judge Wallace held, however, that the statutes which the board were endeavouring to enforce unquestionably belong to the category of police regulations, the power to establish which had been left to the individual States, and it was not apparent how the method proposed by the board impaired in any just sense the privilege granted to the Telegraph Company by the law of Congress. The privilege to maintain telegraph wires "over and along" post roads was not to be construed so literally as to exclude regulations by the State respecting location and modes of construction and maintenance demanded by the public interest and sentiment in each locality. In this view of the case Judge Wallace directed that an order be entered

Digitized by Google

denying the injunction asked for by the Western Union, thus leaving its poles and wires subject to the tender mercies of the board. With regard, however, to the wires and cables of the company placed along and under the elevated railroad structure, the Judge held that they were not in anybody's way and were not objectionable, and must therefore not be interfered with. This little concession was something perhaps; but the defeat on the main issue may be serious to the Western Union Company, as it has a great many miles of wire throughout this city on pole lines and housetops; and as the board "means business" there seems nothing now to prevent those poles and wires from being chopped down, a performance which we are promised this week.

It is a trifle unfortunate for the Western Union Company, if it is in earnest, that some of its own experts recently should have filed affidavits with the board as to the successful operation of underground electrical systems, and that the company cannot very well fall back upon the results of its underground work in other cities. I believe that in Boston and Chicago, as well as in this city, it has obtained very fair results from its underground wires and cables, and so far as this city is concerned it would have done much better but for the fact that the Steam Heating Company down town persisted in turning the Western Union subway into a witches' cauldron, in which the cables were stewed and boiled, like so many eels, and until there was no virtue left in them. That the Board of Electrical Control is determined to have its authority respected in this matter may be inferred from the fact that it has already used its axe to some purpose up town. Last Saturday it made a raid on the wires of the West Side Electric Light Company, which put in a Fort Wayne Jenney plant, and having failed to obtain a franchise from the board, settled down cheerily to business without one. It ran its circuits in every direction wherever a customer offered, and "by strict attention to business" was really getting along very nicely, and turning more than one honest penny; but all of a sudden the myrmidons of the board swooped down on it, and before the company knew what had happened about 10,000 feet of its wire had been carried off and dumped in the Corporation yard. I am sorry for the company, and it would be interesting to know just why it could not obtain a franchise; but, of course, to engage in business in this extensive manner without any official warrant was very much like flying in the face of Providence, and it was utterly impossible that the board should long tolerate this defiance of its authority.

I might add that since I wrote the earlier part of my letter the cutting campaign has actually begun, and a large number of poles and wires have been cut down within a small district extending, roughly, from Fourteenth-street to Twenty-third-street and Broadway and Sixth-avenue. The work has been witnessed by large crowds of people, and has been attended with exciting incidents, including the fall of one rotten pole on a street car, whose inmates it greatly frightened, the laming of one young lady, who stubbed her toe against the bolt of one of the posts, and the killing of a lineman jerked from a window, his companion being also seriously hurt. As the result of this work other districts besides those over which the wires run have suffered the loss of their electric lights, and the gloom of the streets at night, even where the restored gas lights have been in full blaze, has been most dismal and depressing. People are beginning to realise very clearly what a blessing the electric light is, and all the newspapers comment on the dreary effect which the extinction of the arcs has had.

The controversy over the storage battery patents has been carried forward another stage by the action of the Electrical Accumulator Company, which has filed a disclaimer in the way suggested by Judge Coxe, and has limited its patents to storage batteries made by the application of the active material in the form of paste, paint, or cement. This disclaimer has been approved by the Court, and an injunction issued restraining the Julien Company, the Fourth Avenue Railroad Company, and any others, from the use of batteries of that type. The Julien cars are still running, however, on Fourth-avenue, as the company state that they do not make their batteries in that way, their active material being applied, it is alleged, in the form of a powder. During the present week we have been honoured with a visit from the Boston Board of Aldermen, investigating the rapid transit problem. The Board were given a run, which they enjoyed very much, on a Julien car, and some of them think that storage battery cars would be a good thing in Boston. The Julien Company have published a statement this week giving the figures of the operation of their last car, No. 7, put in operation on the Fourth-avenue road, making 57 miles daily in five round trips. The earnings during the past 40 days of this car have been $998. 10c., exclusive of 998 transfers, for which it gets no credit. This is at the rate of $9,106. 75c. per annum, while the average earnings of horse cars on the same line are only $6,387. 50c. Deducting from this $4 a day for driver and conductor, $3. 60c. per day for motive power, wear and tear, and royalty, and 6 per cent. interest on $6,000, which is the cost of the car, with battery racks, stationary motors, switches, &c., the net earnings for the year of the storage car are $5,972. 75c. During the forty days that the car has been in operation up to date neither the batteries nor the motors have required attention or the expenditure of a dollar for renewals or repairs; and it is stated also that on car No. 1, which went into service on the 1st of September last, the batteries, when examined for the first time on April 8, were found to be in as good condition as when put in service, although they had not been lifted from the cells in the whole period to be cleaned or inspected. It will be admitted that these are remarkable statements, but as the company is ready to take all the business that comes to it under penal guarantees, it will be seen that they have the courage of their figures and convictions.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *April* 30, 1889.

The Vienna Telephone Company have just held their annual meeting. The position of the company is a good one. After declaring a dividend at the rate of 8 per cent., the shareholders decided on increasing the company's capital from 800,000fl. to 3,000,000fl. The number of subscribers is increasing so rapidly that a new exchange is being built to accommodate 3,000 more. At present 2,000 subscribers are connected. This will enable the company to connect up to 5,000. The subscription is now 100fl.; a year ago, when it amounted to 150fl., the number of subscribers was only 800. Nearly all the lines in Vienna are underground, and new cables to accommodate 1,000 subscribers are to be laid this year. The new exchange will be fitted up with an improved multiple board to be made by Mr. Otto Schaffler.

The new central electric light station of Messrs. Siemens and Halske is being pushed forward vigorously, and the chimney is nearly finished. They hope to begin working in the autumn.

Mr. Werndl, the general manager and principal owner of the great small-arms factory in Steyr, died suddenly on April 28. Mr. Werndl was a remarkable man; the great factory in Steyr was his own creation, and has put out since 1867 more than 2,100,000 rifles, and is now working on supplying the Austrian and German Governments with their new repeating rifles, turning out over 10,000 a week in Steyr and Vienna. Mr. Werndl began as a small gunsmith. During the years 1882 to 1886, when the factory had little to do, he busied himself with electrical experiments, and was the first in Austria to make use of the electric light on an *extended* scale. He also made many experiments in using water-power to drive his dynamos, and succeeded so well that many followed his example. It was also entirely due to him that the late Electrical Exhibition was held in Steyr.

CORRESPONDENCE.

DR. LODGE'S EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Some of those who were present at the reading of Dr. Lodge's Paper before the Institute of Electrical Engineers were interested to notice a curious incidental phenomenon which occurred in the course of the experiments. The miniature rain-storm was in full swing, the two zinc tanks being connected with the Wimshurst machine by wires perhaps four metres long. The phenomenon appeared on one of these wires. Whenever a spark was produced in the circuit a faint luminosity, about the size of an egg, appeared to run along this

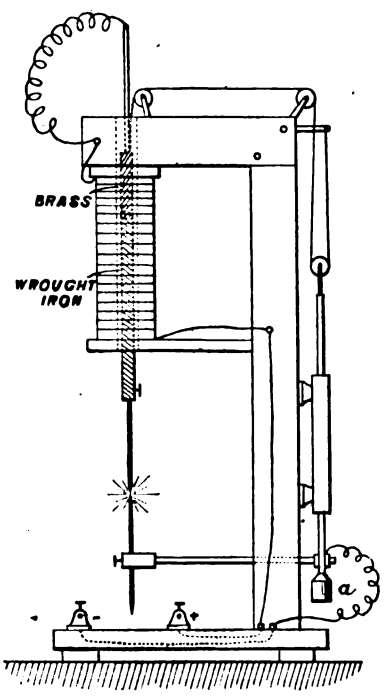
Digitized by Google

wire from one end to the other, occupying perhaps a second in doing so. "That," said Dr. Lodge, "is a brush." No doubt his explanation was correct as far as it went, but he did not explain why the brush seemed to *run along the wire*. I had always thought that an electric current, so far from "flowing," occurred almost simultaneously at all parts of a circuit, or at any rate flowed at such a pace that if it were visible its motion could not be followed by the eye. But here was a brush, resembling nothing so much as a luminous mouse, which was distinctly seen to travel along the wire, occupying an appreciable time in transit. Why did it not "occur" simultaneously at all parts of the wire? Is this another case of the persistence of an image on the retina? I shall be grateful if someone will enlighten the darkness of IGNORAMUS.

ARC LAMPS FOR AMATEURS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I designed some years ago a small arc lamp easily made up by amateurs. The regulating mechanism is the same as that described in your last issue, p. 689, but I think it capable of giving a steadier light, and it can be used for light-projecting by means of a reflector. This lamp is principally convenient for amateurs because it is nearly all made of wood. The box *a* is to hold small shot necessary to adjust the lamp



according to the current supplied.—Yours, &c.,

R. P. BOUQUET, Ingénieur des Arts et Manufactures.

Havre, 9, Rue Caligny.

LAHMEYER'S SYSTEM OF REGULATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to your note on the Müller and Lahmeyer system of distribution, it is interesting to note that this is an extension of Prof. Perry's method of maintaining constant potential at the end of a circuit, which was patented about 1882.

The advantage of the differential winding over plain series is questionable, for though it doubles the range of E.M.F. it involves variable lead of the brushes, and, like all differential winding, is expensive in copper.

The use of compensating series dynamos was proposed for the Birmingham electric lighting scheme, and was included in a provisional specification dated June, 1888.

Although the method at first sight looks very promising, it seems questionable whether it has any advantages over compound or regulated shunt dynamo when the feeders are supplying a continuous network of distributors.

In cases where several isolated centres are supplied from a single station the system would be very useful, but such cases are not likely to occur in low-tension distribution.

The disadvantage of so many extra machines is obvious.—Yours, &c., R. H. HOUSMAN.

Birmingham, April 30, 1889.

THE INJUNCTION AGAINST THE JULIEN COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We beg to hand you copy of injunction order issued under the recent decision of Judge Coxe in the United States Circuit Court for the Southern District of New York, in the case of the Electrical Accumulator Company against the Julien Electric Company, which has been forwarded to us by the solicitors of the Electrical Accumulator Company of New York.—Yours, &c., H. DELL,

Secretary Electrical Power Storage Company (Limited).

London, May 1, 1889.

[Our readers will scarcely be interested in the legal formularies of the United States Courts, but the following is the claim upon which the injunction is based:—"Any polarisation or secondary batteries containing or embodying an electrode consisting of a support coated on one or more faces, with an active layer of absorptive substance, such as metal or metallic compound, applied thereto in the form of a paint, paste, or cement, and practically insoluble in the electrolytic liquid, so as to be or instantly become spongy, and thus capable of receiving or discharging electricity." Some further information will be found in our New York letter in the present issue.—ED. *E.*]

COMPANIES' MEETINGS & REPORTS.

The Indo-European Telegraph Company (Limited).

The twenty-second ordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Monday, Mr. J. Herbert Tritton, the Chairman of the Company, presiding.

Mr. W. ANDREWS, the Managing Director, read the notice convening the meeting, and the seal having been affixed to the register of shareholders, the report and accounts were taken as read.

The CHAIRMAN said: I have now to move the ordinary resolution:

"*That the report and accounts now submitted be received and adopted, and that a dividend be and is hereby declared for the half-year ended 31st December, 1888, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, together with a bonus of 20s. per share, both free of income tax, making in all 10 per cent. for the year.*"

Mr. H. WEAVER seconded the resolution.

The CHAIRMAN: Before I put the resolution perhaps you would allow me to make one or two remarks upon the course of business during the year 1888. You will have observed that the receipts amount to £110,327 which is an increase of £6,036 beyond the gross receipts for 1887. The expenses amount to £52,393, as compared with £48,620, which shows a gross increase of expenditure of £3,772. On the commercial account, under the head of salaries, we have paid away £500 more in wages. That is mainly due, I believe, to the fact that this Company transacted for a month the whole of the Indian business. During the year 1888 there is also an increase of something like £250, which has been caused by two years' rent paid for the Warsaw station in one year. There are one or two other minor increases; but the chief increase is £955 in agency expenses, which arises from the fact that these expenses, which formerly were partly borne by the Gulf Department of the Indian Government, are now altogether borne in this country by this Company. There is one item in the expenditure which I think will, without doubt, meet with your approval, and that is a donation of 200 guineas, which the Board felt themselves free to make to the German Inundation Fund under the distressing circumstances of the time. Turning to the maintenance department, there is an additional outlay, consequent upon a reorganisation of the staff, of £1,608, which results in a lessened expenditure in the future. This will not recur. Turning to the traffic, I have to observe that it is from some points of view slightly discouraging, although, as you will observe, there is, on the whole, an increase. The one discouraging feature is, in fact, that the Indian traffic pure and simple does not bring us in now what we might reasonably have expected it would bring us in. The rate for Indian messages was lowered in the year 1886, and we have not benefitted; on the contrary, we have suffered from that lowering of the rate. The messages have not been increased as some expected they might have been increased. The increase to which I have referred, therefore, has been made up out of other than purely Indian messages—that is to say, trans-Indian, Australasian, Persian, and South Russian messages. It may be interesting to you also to know—which is again a somewhat discouraging fact—that the number of words per message is steadily decreasing. In the year 1880 the number of words per message was 18·83; it has gradually and steadily declined until in 1888 the number of words

Digitized by Google

per message was only 12·66. This must be attributed, we suppose, to the greater perfection in what is called "coding," whereby very much more is conveyed than the number of words employed. As respects the Indian messages, I have already mentioned that there is actually a falling off. This falling off is not only in the number of messages, but also in the number of words. This falling off in the number of words does not apply to our trans-Indian business. A review of all the circumstances drives us to the conclusion that it is not so much the tariff which regulates the traffic as the activity or sluggishness of trade or commerce. At these great distances, where the cost of telegraphic messages must be appreciable, owing to the enormous mileage traversed and the necessarily great outlay upon special lines of communication, which have to be maintained in the most perfect order, the tariff can never be so low as upon lines where messages travel longer and shorter distances indifferently, so that there may be a mean distance which may be comparatively short when all the traffic is taken into consideration. For instance, the minimum distance from this country to India is 5,848 miles to Kurrachee; but this distance is largely increased on the average because the bulk of the traffic is exchanged with Calcutta, 7,624 miles; or Bombay, 6,617 miles; or Madras, 7,337 miles; or Rangoon, 8,600 miles; or with the Presidency towns. Then, in the case of Australia, there is a minimum distance of 11,804 miles; but this distance is often very largely increased. For instance, Melbourne is 14,349 miles distant, and so on; so that looking at the large portion of the globe traversed by Indian and trans-Indian messages, it is certainly a cause for astonishment and congratulation to see to what marvellous perfection the Indian Government and Indo-European Company have brought the service, and the perfect state of communication with India by telegraph. Next year there will be a telegraph conference held in Paris, to which we look forward with feelings not altogether unmixed with anxiety. We never know quite what may be said or what may be done at these telegraph conferences, and we have, as you are aware, large interests to foster and protect. In the past the reductions which have been made at these conferences have not proved very fruitful, unfortunately; for the European telegraphs as a whole are worked at a loss. They are mostly in the hands of Governments as we know. I believe I am right in saying that our own British telegraph service is worked at a loss, and the question arises how far the senders of messages, who send them because they expect to make a profit out of the business they are conducting, are to be practically subsidised at the cost of the general community. It seems to me that this is a question which ought to receive the serious attention of the proper authorities. The telegraph, in fact, ought to pay for itself and return a fair interest upon the capital and labour employed, just the same as any other business, whether its proprietors are States or private individuals like ourselves. In conclusion, gentlemen, I can only express the satisfaction which you and we may feel at the very satisfactory manner in which the business has been done during the past year. That has been largely owing to the exertions and efficiency of the staff, which is second to none in the telegraph service. That staff has been watched over and looked after by our good friend, the managing director, Mr. Andrews, who devotes a very large amount of energy and business ability to the conduct of our affairs. We owe to him, as well as to the staff, a great deal of thanks. There is one other matter to which I must also allude before I sit down. You will have observed the report states that Colonel Holland was compelled to resign his seat at the Board. That he did, to the great regret of his colleagues; but since then he has died. His colleagues regret his death exceedingly, and you, gentlemen, I am sure will also regret it extremely. Most unexpectedly he has passed away from us, and it will be your wish I am sure that we should express to his family through his son, who is not able to be with us to-day, the sincere sympathy which we all feel with the family at the loss which they have endured. Colonel Holland was Chairman of this Company for nearly twenty years; we could not have had a better Chairman, or one more conversant with its affairs or more experienced in Indian business. We shall feel his loss very much indeed. Gentlemen, I beg to move the resolution which I have already read to you. That resolution has been seconded by Mr. Weaver; but before I put it, if there is any gentleman who wishes to make any observations or ask any questions, I shall be happy to hear them.

Mr. JACKSON: Mr. Chairman, may I be allowed to intrude for a few minutes to ask a question with reference to the possible future of this Company—I mean in view of the expiry of its concession. I think we all ought to feel, as I have no doubt we do all feel, that the admirable management in the past and the sound judgment of the Board has secured for us a very satisfactory return; but I think, sir, it must be patent to everybody that the assumption by Government of the telegraphic service as part of the postal service of every country is but a question of time, probably only of a short time. I would very respectfully, on your accession to office, ask your serious attention to that point. While I feel the validity of your remarks with reference to our late Chairman, I also feel that we have reason to congratulate ourselves on having a gentleman of your position and financial ability to take his place. But I think the matter I have referred to is one we may in all respect ask the Board to take into their consideration in view of the future. We have seen in reference to our neighbour, the Submarine, that there has not been that consideration or solicitude for the interests of shareholders exhibited by the Governments concerned that we might naturally desire or expect for the pioneers who have undergone—perhaps not so much in their case as in our own—all the brunt and the heat and burden of the day. Still, I think forewarned is forearmed, and I think the Directors might very fairly consider the advisability of returning, in whatever form they see to be possible, a portion of the capital to the shareholders, so that when the time does come we shall not, at all events, be caught in the toils of diplomacy and have to suffer in our pockets by the resumption of this concession by a Government concern. I see that we have something like 25 per cent. of our capital in the reserve fund. Of course, that is necessary for the backbone of the Company in order that you may be able to meet every possible casualty or contingency; but, at the same time, many of us shareholders would like to see some portion of the money "in fisto." In what way that can be done must, of course, depend on the judgment and care of the Board; but still, it is a matter which we ought, I think, to deal with. I took the liberty of writing to your predecessor, Col. Holland, but his health was infirm, and he was unable to give the matter attention. I have nothing further to say, except to express the satisfaction of myself—and, I think, of every shareholder—at the excellent results shown. I should like to say just a word with reference to the Indian traffic. Of course, as you have pointed out, it depends more on commercial activity and prosperity than on the reduction of the traffic; but it is an abnormal thing that a reduction of tariff should not lead to increased trade. Of course, ultimately we may hope for that. However, I should consider that you might freely dispose of a portion of the reserve fund, because with a smaller amount of capital the same dividend might be paid, and in such a way we might safeguard the interests of the Company. I am much obliged to you for your attention to my remarks.

The CHAIRMAN: No other gentleman rising to put any questions, I will reply to Mr. Jackson. I think Mr. Jackson was one of the earliest shareholders in the Company, and he will remember that there was in the old Articles of Association a clause whereby we were obliged to establish a sinking fund; but under the force of circumstances to which he alluded when he mentioned the pioneers who have had to bear the heat and burdens of the day, it was impossible to carry out that arrangement during the first few years. When we made no money and paid no dividends it was impossible for us to start a sinking fund, but latterly we have been in circumstances which have enabled us to put by money until now we have something over 25 per cent. of our capital in reserve. That we must look upon partly as a fund against contingencies and partly in the light of a sinking fund. Our concessions come to an end in something less than 20 years. There is a clause both in the Russian and in the Persian Concession under which the Company is bound to come to terms with those Governments, and we hope and believe that that implies that the Governments will conceive themselves reasonably bound, in considering those terms, not to enter upon a course of confiscation. We do not for a moment suppose they would think of anything of the sort; but on our part we must also be reasonable if we expect them to be reasonable, and no doubt we shall find both parties to the Concession reasonable when the time arrives. The point has been constantly before the Directors. It receives and shall continue to receive our best attention; but whether or no it is possible to follow out Mr. Jackson's implied desire that we should actually divide up our reserve fund I cannot now say. My own feeling, both in this and other places, is that a body of shareholders is well advised in seeing that the directors so conduct their business that they are enabled to have a very substantial amount in reserve against contingencies of all sorts and kinds. That would be my own feeling very strongly both here and elsewhere. Gentlemen, I thank you for the patience with which you have listened to me, and for the way in which you have received the motion, which I now beg to put.

The motion was then put and carried unanimously.

The CHAIRMAN: I have now to state that in accordance with the Articles of Association the following Directors retire by rotation:—Mr. C. W. Earle and Mr. J. Von Berenberg Gossler. Both these gentlemen are eligible for re-election and offer themselves accordingly. If it be your pleasure I will put the resolution that these two gentlemen be and are hereby reelected Directors of the Company.

Major-General G. B. TREMENHEERE, R.E., seconded the resolution, which was carried.

Mr. WOODMAN next moved—

"*That Messrs. C. F. Kemp, Ford and Co. be re-elected auditors for the current year.*"

Mr. SMITH seconded the motion, which was adopted.

The CHAIRMAN: That, gentlemen, concludes our business, and I have only now to thank you for your attendance.

Mr. JACKSON: Gentlemen, I do not think we can leave this, the first meeting at which we have the pleasure of welcoming our new Chairman, without passing a vote of thanks to him and the Board, and I beg to propose—

"*That the best thanks of the shareholders be accorded to our Chairman and Directors for the conduct of our affairs during the past year.*"

Will some gentleman kindly second that?

The motion was seconded by Mr. WOODMAN, and adopted.

The CHAIRMAN: Gentlemen, I thank you for this renewed vote of confidence and thanks on your part. We shall continue to do our best to merit it.

The meeting then closed.

The Great Northern Telegraph Company of Copenhagen.

The following is an abridged report of the general meeting held at Copenhagen on April 27 last, under the presidency of Mr. F. Zahle. The report of the Directors was summarised in our issue of April 26.

The chairman of the Company, Mr. C. F. TIETGEN, in rendering an account of the working of the Company during the year of 1883, first referred to the state of the Company's cables, which had not been quite so satisfactory as in the previous year, as the interruptions had been more frequent. In Europe thirteen interruptions and in the Far East eight had occurred, without, however, affecting the receipts in any sensible degree. The Company's cable steamer in Europe, the "H. C. Orsted," had been employed for 143 days, including eight days in the laying of a cable in the

Digitized by Google

Baltic, between Gjedser in Denmark and Warnemünde in Germany, for the joint account of the Danish and German Governments. The repairing steamer in the far east, the "Store Nordiske," had been at work for 146 days, out of which 50 days had been for foreign account.

The Traffic Revenue had exceeded that of the year of 1887 by about £8,000. From this fact the shareholders would no doubt have drawn the inference that the losses anticipated as consequential upon the Chefoo Convention—a subject which was largely referred to in the last report—had not yet been felt. And so it was; because the Convention had not yet been ratified by the supreme authorities in Peking.

The Company's position in China.—It would have carried him too far here to enter into details of all the complicated phases through which this question had passed, a description of which might only prove misleading to the uninitiated. The fact was, however, that the Company had as nearly as possible come back to the point of departure of the previous year, viz.:—That all the parties interested sincerely desired a final solution; and since then it would appear that it had been more a question of form than of any substantial divergencies which had stopped the way of the ratification. With a little goodwill on all sides—and the Company had certainly shown much of this—the affair could no doubt at any time be settled very expeditiously.

Financial Considerations.—Meanwhile the Company remained in a state of uncertainty with regard to their future position in China, and considering the retardation which had taken place, and which left the door open to the unforeseen, they had considered it prudent to deal with the surplus revenue as nearly as possible as in the previous year; and further, to apply a part of that surplus to an increased amortisation of the 1881 Bonds. This measure would be understood by the shareholders when they considered that 5 per cent. is paid on these bonds. The unredeemed amount of the same being only about £40,000 it would hardly be worth the while or the expense to resort to a conversion. With regard to the 1883 Bonds the Company had in this respect no rights before 1898.

China, &c., Inland Enterprises.—The extension of inland Chinese telegraph lines had not progressed much during the past year, but in Corea a land line had at last been constructed and opened for traffic on the 18th July, 1888, to convey messages from the capital of Seoul to Fusan, which place was connected with Japan by means of one of this Company's cables.

Relations with Russia.—The Wheatstone system had been introduced and well organised on the Russian land lines from St. Petersburg to Wladiwostock (the terminal station on the Pacific). The results of the service on these lines had been satisfactory, and no doubt would still improve.

Extension of the Company's Lines.—In accordance with the agreements with the Eastern Extension Company, this Company had become co-proprietors of four short lengths of cable between the Colony of Hong-Kong and the opposite Continent of China at Kowloon. Two of the cables were worked in connecting Hong-Kong with Canton, and the other two served for telephonic purposes between Hong-Kong and Kowloon. The share of this Company's contribution towards the cost of these cables had been taken from

The Reserve Fund.—Out of this fund the cost of spare cable, manufactured in London, had also been defrayed, and it could be expected that the charge under this head might in coming years be larger, owing to the increasing danger to which the cables, particularly those in the North Sea, were exposed by the trawl fishing.

International Scandinavian Exhibition at Copenhagen.—The Company had carried out its intention of exhibiting on that occasion, and the result had been that not only the first prize had been awarded to them for telegraphic and electrical instruments, but that they had also gained a special honourable mention.

Famine in China.—The Company had contributed £500 towards the fund raised in London by the Lord Mayor for alleviating the distress of the sufferers.

The resolutions set out in the Directors' report (which appeared in our last issue) were unanimously passed.

Five shillings per £10 share, representing the final dividend for 1888, is now payable at the Company's bankers, Messrs. C. I. Hambro and Son, 70 Old Broad-street, London, E.C., against coupon No. 15.

The Brazilian Submarine Telegraph Company (Limited).

Report of the Directors for the half-year ended 31st December, 1888, to be submitted to the thirty-first ordinary general meeting, to be held at Winchester House, Old Broad-street, London, E.C., on Wednesday, the 8th inst., at 12 o'clock:—

1. The Directors' accounts and balance-sheet are for the half-year ended 31st December, 1888.

2. The revenue for this period amounted to £133,708. 15s. 1d., and the working expenses to £23,553. 14s. 8d. After providing £12,880 for debenture interest and sinking funds, and £1,985. 6s. 10d. for income tax, there remains a balance of £95,289. 13s. 7d.; to this is added £4,539. 3s. 7d. brought forward from June 30 last, making a total of £99,828. 17s. 2d. First and second interim dividends amounting to £39,000 have been paid, and £40,000 transferred to the reserve fund, leaving the sum of £20,828. 17s. 2d. to be carried to the next account. Of this amount the directors intend distributing £13,000 to the shareholders with and in addition to the quarterly dividend payable in June.

3. In accordance with the provisions for repayment of the first issue of debentures, dated July 31, 1884, 145 bonds, representing £14,500, were drawn on the 12th inst. for payment at par on July 31 next. This, with the previous drawings, will make a total repayment of £65,500, leaving £84,500 of the first issue of debentures outstanding.

4. The question of a reduced rate to Brazil has been under the consideration of your Board for some time, and it has been decided that reductions should be made in the tariff to Madeira, St. Vincent, and Pernambuco. It is anticipated the alteration will at the commencement affect the Company's revenue, but that the growth of traffic resulting from the reduced rates will greatly diminish the possible loss.

5. Under an arrangement with the African Direct, the West African and the Eastern and South African Telegraph Companies, additional traffic will be brought to this Company's lines between St. Vincent and Europe by the new cable now being laid to the Cape of Good Hope.

6. The various sections of the Company's line are in good working order.

The West India and Panama Telegraph Company (Limited).

Report of the Directors and the accounts for the half-year ended 31st December last, to be submitted to the twenty-fourth ordinary general meeting to be held at Winchester House, Old Broad-street, E.C., on Wednesday, the 8th inst., at 3 o'clock:—

1. The amount to credit of revenue is £43,061. 16s. 9d., and the expenses have been £21,425. 1s. 2d., leaving a balance of £21,636. 15s. 7d., which, with the balance of £1,255. 3s. 6d. brought from last account, makes a total of £22,891. 19s. 1d. Of this sum the Directors have placed £1,000 to reserve, leaving an available balance of £21,891. 19s. 1d., with which it is proposed to deal as follows:—

Payment of 12s. per share on account of arrears of dividend on the First Preference shares	£20,737	16	0
Balance to current half-year's account	1,154	3	1
	£21,891	19	1

2. The traffic receipts for the six months show an increase of £1,050. 9s. 3d., as compared with the corresponding period.

3. The directors are glad to state that comparatively few interruptions of the cables have occurred during the half-year, and that all sections of the company's system are now in working order.

4. The new line of cables mentioned at the last general meeting as having been laid by a French company to connect Santiago de Cuba with Hayti, San Domingo, Curacoa and Venezuela on the coast of South America, was authorised by the Spanish Government to be opened for traffic in February last.

5. Mr. Cyrus W. Field having resigned his seat at the board, the International Ocean Telegraph Company nominated as his successor Mr. George von Chauvin, the representative in England of the Western Union Telegraph Company of America, and the board have elected him a director of the company.

6. In accordance with the articles of association, Henry Holmes, Esq., and Henry Weaver, Esq., retire at this meeting, and offer themselves for re-election.

7. John George Griffiths, Esq., the auditor, also retires, and offers himself for re-election.

The West Coast of America Telegraph Company (Limited).

Report of the Directors to be submitted to the twelfth ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, London, E.C., on Wednesday, May 15th, at 1 o'clock.

The balance-sheet and revenue account show a gross income of £65,714. 15s. 4d. for the year ending 31st December, 1888, against £57,893. 9s. 9d. for the previous year. After deducting debenture interest and all other charges, there remains a nett profit of £30,646. 4s. 6d. for the past year, as compared with £23,114. 18s. 1d. for the year 1887. Adding the amount of £333. 19s. 3d. brought forward, makes a total of £30,980. 3s. 9d. Out of this the following dividends have been paid :—

In July, 1888	4s. per share,	£6,000
In January, 1889	6s. „	9,000
Total		£15,000

The directors now recommend a further distribution of 2s. per share, payable the 16th inst., making 6 per cent. for the year, to write off £500 from the value of the repairing steamer "Retriever," thereby reducing her valuation in the books of the company to £17,000, and to add £12,000 to the reserve fund, making the latter £39,000, which distribution will leave £480. 3s. 9d. to be carried forward. The earnings of the company have been materially increased by a satisfactory state of business in the countries served by its lines. In the month of December the directors purchased an existing land line between Valparaiso and Santiago, which by improved working is already giving good returns on the outlay of capital involved. They have also made arrangements for direct communication between Iquique and Pisagua, a port of increasing importance, by means of a land line. The cables and repairing steamer are kept in perfect working order.

The directors regret to have to report the loss of an esteemed colleague through the death of Mr. Thomas Fielden Campbell. They have filled the vacancy by electing Mr. Frederick Walters to a seat on the board. The members of the board retiring by rotation are Mr. Alfred Marshall and Mr. Frederick Walters; both being eligible, offer themselves for re-election. The auditor, Mr. J. Weise, of Messrs. Turquand, Youngs and Co., retires, and is eligible for re-election.

NEW COMPANIES REGISTERED.

BROMPTON ELECTRIC FITTINGS COMPANY (LIMITED).—This company was registered on the 20th inst., with a capital of £2,000, in £1 shares, to manufacture and supply electric light and the fittings for the same, and also electric and other bells, stones, and artistic work in iron, brass, copper, or other metals or materials.

GUTENSOHN AND JAMES.—This company is registered with a capital of £150,000, divided into 15,000 shares of £10 each. The objects of the company (amongst other things) are to purchase, or otherwise acquire, the Royal patents of Gutensohn and James for—(1) an invention for improvements in the process of pickling or cleaning the surface of iron or other metals previous to coating such surface with tin or other metal; (2) an invention of an improved apparatus for pickling or cleaning the surface of iron and other metal, to prepare the same for coating with tin or other metal; and to grant licenses in respect of such patents, and to purchase or hire land and to erect buildings for the purpose of carrying on the company's business of tin plate manufacturers and any other business. The application of electricity to tin plating is, we understand, the improved process referred to.

PATENTEES COMPANY (LIMITED).—This company was registered on the 18th inst., with a capital of £25,000, in £1 shares, to construct public works and conveniences of all kinds, including railways, tramways, wharves, embankments, sewage, drainage, sanitary, water, gas, electric light, telegraphic, telephonic, hydraulic, &c. The number of directors is not to be less than two nor more than seven; qualification, 250 shares; the subscribers are to appoint the first; the company in general meeting will determine remuneration. Registered office, Leadenhall-buildings.

CITY NOTES, &c.

THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION.—ISSUE OF DEBENTURES.—The directors of the above Corporation invite applications for an issue of £75,000 Six per Cent. First Mortgage Debentures in bonds of £50, £100, and £500 each, upon the security of the whole assets of the corporation, including the uncalled share capital. The subscribed share capital is £237,353, in shares of £5 each, of which 27,057 are fully paid, and 25,517 are only £4 per share paid. The debentures will be issued at par, and will carry interest at the rate of 6 per cent. per annum, payable half-yearly. The debentures will be redeemable at par in 1903, or upon the corporation giving three months' notice in writing, at the rate of 105 per cent. The object of the issue is to obtain funds for extending the business of the corporation.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The directors recommend a final dividend at the rate of 7 per cent., making, with the interim dividend, a distribution of 6 per cent. for the year ended March 31, 1889, after writing off £2,500 and carrying forward about £1,700. For the previous twelve months the distribution was at the rate of £5. 7s. per cent.

MESSRS. MIX AND GENEST, BERLIN.—The business till recently carried on by Messrs. Mix and Genest has now been constituted under the title of the Actien Gesellschaft Mix and Genest, Telephon-Telegraphen and Blitzableiter Fabrik. The capital in shares amounts to 1,200,000 marks. All the assets of the former firm, namely, 840,000 marks. have been transferred to the new company, and the remaining shares for 360,000 marks have been subscribed for cash payment. There are no mortgage debts or other liabilities. Of the sum paid, 160,000 marks will be reserved for working capital, and the remaining 200,000 marks will be devoted to greatly extending the works, more particularly as regards one of their specialities—the erection and working of telephonic installations. The financing of the company has been undertaken by the banking firm of C. W. Schnoeckel, of Berlin.

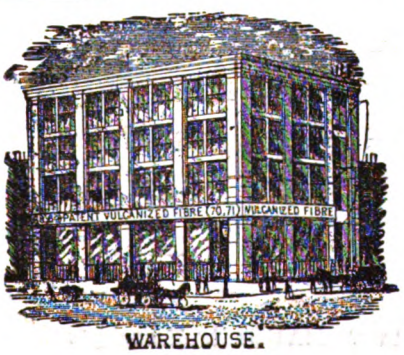
MR. SAMUEL ELLIOTT, manufacturer of electric wire casings, of Albert Works, Newbury, has taken offices and show rooms at 63, Finsbury-pavement, E.C.

PERSONAL.—Messrs. Thompson, Ritchie and Turnbull, of Old Broad-street, announce the retirement of Mr. R. O. Ritchie from the firm.

——— We are informed that Messrs. Roothaan, C. M. V. Roothaan and C. Alewijnse, of Nijmegen (Holland), have entered into partnership under the title of Roothaan and Alewijnse. This firm intends to occupy itself principally with the manufacture of incandescent lamps.

——— We are informed that Mr. Arthur W. Slater has withdrawn from the Galway Electric Company and has transferred his interest therein to Mr. James Perry, who assumes all liability in connection therewith, and continues the business on his own account.

THE NON-CONDUCTOR OF ELECTRICITY.



WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

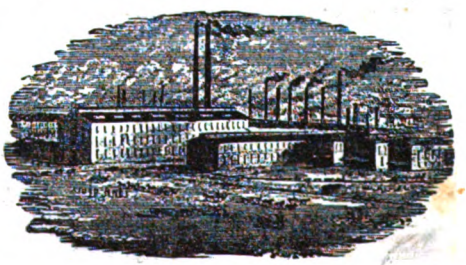
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.
